"Agriculture is the most healthful, most useful and most noble employment of man."—WASHINGTON.

THE

TROPICAL **A**GRICULTURIST:

(ESTABLISHED 1881.)

A MONTHLY RECORD OF INFORMATION FOR PLANTERS

OF

TEA, CACAO, COFFEE, PALMS, RUBBER, CINCHONA, SUGAR,
RAMIE, COTTON, TOBACCO, SPICES, CAMPHOR, RICE,

AND OTHER PRODUCTS SUITED FOR CULTIVATION IN THE TROPICS:

Circulating in India, Ceylon, Burma, Straits, Java, Sumatra, Borneo, Northern Australia,
Queensland, Fiji, Mauritius, Natal, West Indies, South and Central America,
California, Southern States, and throughout Great Britain:

EDITED BY

J. FERGUSON,

of the "CEYLON OBSERVER," "CEYLON HANDBOOK AND DIRECTORY," &c.

"It is both the duty and interest of every owner and cultivator of the soil to study the best means of rendering that soil subservient to his own and the general wants of the community; and he, who introduces, beneficially, a new and useful *Seed, Plant or Shrub* into his district, is a blessing and an honour to his country."—SIR J SINCLAIR.

VOL. XVII.

[Containing Numbers I to XII: July, 1897, to June, 1898.]

CEYLON: A. M. & J. FERGUSON, COLOMBO.

LONDON:

JOHN HADDON & Co.; KEGAN PAUL, TRENCH, TRÜBNER & Co., LTD.; LUZAC & Co.; &c.

HONGKONG AND YOKOHAMA:—KELLY & Co.—JAVA: MESSRS. JOHN PRYCE & Co.,

BATAVIA, G. KOLFF & Co.

MDCCCXCVIII.

THE

MONTHLY RECORD OF INFORMATION FOR PLANTERS

OF

J. ERB GUBSON,

VOL. XVII.

MEXICO 7 111

TO OUR READERS.

In closing the Seventeenth Volume of the "*Tropical Agriculturist*," we would as usual direct attention to the large amount of useful information afforded and to the great variety of topics treated in the several numbers. From month to month, we have endeavoured to embody in these pages the latest results of practical experience and scientific teaching in all that concerns tropical agriculture; and our ambition has been to make our periodical not only indispensable to the planter, but of service to business men and capitalists, never forgetting that agriculture trenches upon every department of human knowledge, besides being the basis of personal and communal wealth.

While directing our attention chiefly to the products prominently mentioned on our title-page, we have always taken care to notice minor industries likely to fit in with sub-tropical conditions; and our readers have an ample guarantee in the index pages before them, that, in the future, no pains will be spared to bring together all available information both from the West and East, the same being examined in the light of the teachings of common sense as well as of prolonged tropical experience in this, the leading Crown and Planting Colony of the British Empire.

Special attention has, during the past year, been given to the extension of the fibre industry (in rhea especially); rubber; cacao in Central America and the West Indies as in Ceylon; coffee and allied products in Brazil, Mexico, Costa Rica, East Java, Nyassaland, British Central Africa; Liberian coffee in Sumatra, Java, the Straits Settlements; and to other new developments in coffee, coconuts and tobacco planting, &c., in the Malayan Peninsula and North Borneo, as well as in this Island.

The Tea-planting Industry has sprung into so much importance in India (South as well as North) and Ceylon, as also in Java, that a considerable amount of space is naturally given to this great staple; and we think it will be admitted by impartial judges that the *Tropical Agriculturist* should be filed, for the convenience of planters, in every Tea Factory in this Island, in India and in Java.

A full and accurate Index affords the means of ready reference to every subject treated in this, the Seventeenth volume, which we now place in our subscribers' hands, in the full confidence that it will be received with an amount of approval, at least equal to that which has been so kindly extended to its predecessors.

To show how fully other Products besides Tea are treated in this volume, we may mention the number of entries under several headings as follows:—Coffee (including Liberian) 85; Cacao 25; Indiarubber 34; Coconuts and other Palms 30; and Miscellaneous Products nearly 1,000. In the 17 Volumes, the references to Rubber, Coffee, and Cacao number many thousands, as also to Coconuts and other Palms.

We are convinced that no more suitable or useful gift can be made to the tropical planter or agriculturist, whether he be about to enter on his career, or with many years of experience behind him, than the seventeen volumes of our periodical which we have now made available. They are full of information bearing on every department and relating to nearly every product within the scope of sub-tropical industries.

In conclusion, we have to tender our thanks to readers and contributors, and our wish that all friends may continue to write instructively and to read with approval; for then, indeed, must the "*Tropical Agriculturist*" continue to do well.

J. FERGUSON.

COLOMBO, CEYLON; 4TH JULY, 1898.

Errata.—Page 841, Dr. D. Morris's two Lectures are summarized under the one heading on pages 841-2, June No.

☞ All Planters of New Products or Pioneers in new lands should not fail to order this periodical as their best instructor.—Every Tea Factory, Coffee or Cacao Store, ought to have a file of the **TROPICAL AGRICULTURIST**, which contains a vast amount of information about Tea, and a Record of the Tea and other Produce Sales.

Among the **OLD COLONISTS AND PLANTING PIONEERS** whose portraits with biographical notices, are likely to appear in this new Volume, are Messrs. F. R. and W. SABONADIERE, THOS. WOOD, W. BOWDEN SMITH, C. TOTTENHAM, JOHN CAPPER, R. E. LEWIS, &c.,

ORDER FOR THE
“TROPICAL AGRICULTURIST.”

.....1898.

Sirs,

*Please forward the above publication from the beginning of
Vol. XVIII, 1st July 1898.*

Please send also (lettered as for.....Estate)
Vol. I, II, III, IV, V, VI, VII, VIII, IX, X, XI, XII, XIII,
XIV, XV, XVI, ^{AND}_{OR} XVII, for 1881-2, 1882-3, 1883-4, 1884-5, 1885-6,
1886-7, 1887-8, 1888-9, 1889-90, 1890-91, 1891-2, 1892-3, 1893-4,
1894-5, 1895-6, 1896-7, ^{AND}_{OR} 1897-8.

I am, Sirs,

Yours faithfully,

.....
To Messrs. A. M. & J. FERGUSON,
“CEYLON OBSERVER” OFFICE,
COLOMBO, CEYLON.

✽ "TROPICAL" ✽ AGRICULTURIST ✽

are reminded that with the June Number, already received by them, and the Index and Title-page now issued, the SEVENTEENTH VOLUME (1897-98) is closed.

SUBSCRIPTIONS are due payable in advance for 1897-98, at the following rates:—

For Ceylon { Yearly ... R12	For Europe, &c. { Yearly £1 6s.
and India { Half-yearly ... R7	

N.B.—Subscribers to the *Ceylon Observer* or *Overland Ceylon Observer* R4 (5s.) LESS per annum.

Single copies, R1; back copies, R1½.

Per Volume, R16; cash R15; or £1 1s. and £1.

✍ Those who have not settled for past subscriptions are requested to do so by return of Post, and to send Cheque, Post Office Order, or Bank Draft, in favour of A. M. & J. FERGUSON, Colombo.

Covers for binding the Seventeenth Volume, July 1897 to June 1898 (870 pages) can be obtained for R1.50. Cost of binding and cover R2.50.

WHAT IS THOUGHT OF

THE "TROPICAL AGRICULTURIST."

A gentleman resident in the Central Province, who has as good opportunities of knowing what is of benefit to Planters as anyone we know, sent us the following explicit testimony to the value of the *T.A.* :—

"Since its commencement, I have regularly seen and perused the *Tropical Agriculturist*. There can be but one opinion that its scope and object are highly important, and that it supplies a distinct desideratum, which it is to the interest of every estate proprietor to have available in the bungalow for the use of his *locum tenens*, or superintendent. As a magazine it provides varied and instructive fresh literature at intervals; deprived, as most in Ceylon are, of easy access to libraries; and as years go by it will growingly become 'The Ceylon Encyclopædia' with reference to agricultural operations. Viewing estate property as practically a permanent investment to any proprietor, the trifling charge of R12 per annum—a rupee a month—is certainly of no account, provided the separate numbers are kept, and bound together yearly as a book of reference, for the benefit of the manager and his successors. In that light, as the property of an estate to be handed over just as much as its office furniture, few proprietors would probably refuse to authorise its being taken and filed regularly (if the periodical was brought under their notice), more especially as on looking over the most recent volume one cannot fail to see how much valuable information on 'Tea' has been collated. In the belief that 'Tea' has restored prosperity to Ceylon, and that plantation property is a good investment for capitalists, such should not omit the office and connected equipment so advisable on all 'pucka' estates, a part of which should be the *Tropical Agriculturist*. I find I have gone on writing, but, as I am getting the numbers for the past year ready to be bound, the volume is before me."

THE VALUE OF THE "T.A." TO CEYLON ESTATE OWNERS.—A planting correspondent wrote some time ago:—"I think proprietors should supply every tea estate with the *T.A.* The information in it with regard to everything in connection with tea &c. is invaluable: it would pay its value over and over again. Owners of estates should not leave it to hard-up superintendents to take it in."

A Correspondent writes:—"I venture to say the volumes of the *Tropical Agriculturist* will be at a premium a few years hence: it is a book which is bound to rise in value as time rolls on, and subscribers will probably, if they so choose, be able to sell at a handsome profit, besides having had the benefit of using the information in the meantime."

From a Proprietor:—"I wonder how many planters know what they lose in not subscribing to your wonderful publication? The cost is absolutely nothing, compared to the convenience of having in a bound book all that is interesting and necessary in the literature of their calling. Information culled from a thousand sources, price lists of all produce sold locally, and home advertisements not seen elsewhere, and a hundred other things necessary for them to see and to know. The *T.A.* is, in fact, a convenient file of useful information daily arising and permanently preserved."

Mr. W. T. Thistleton Dyer, F.L.S., C.M.G., of Kew Gardens:—"Sir Joseph Hooker and myself always look out for the successive numbers of the *T.A.* with eagerness, and I keep a file in my office for reference. It is impossible to speak too highly of the utility of such a publication and of the way it is managed."

Sir George King, late of the Calcutta Government Museum:—"I know your *Tropical Agriculturist* well, having carefully secured every number since the beginning. You have succeeded in making it a wonderfully useful magazine of information for planters."

Surgeon-Major Bidie, F.L.S., of the Government Central Museum, Madras:—"I find the *Tropical Agriculturist* a most interesting and useful publication. It finds a place on the table of our Public Library and is much prized."

SAMUEL BUTLER.

“PIONEERS OF THE PLANTING ENTERPRISE IN CEYLON.”

(*Second Series.*)

SAMUEL BUTLER,

PLANTER AND MERCHANT: 1837-1893.

THE late Samuel Butler was one of the founders of the well-known firm of Messrs. Darley, Butler & Co., of Colombo. He left Ceylon in the year 1858, though continuing to be a working partner in his old firm. Few or perhaps none of those who knew him in Ceylon remain, and very few even in England. Mr. Butler, a Worcestershire man, came to Ceylon in 1837 (a year which also saw the advent of the late R. B. Tytler and A. M. Ferguson) in the earliest days of Coffee Planting, and when opinions were unsettled about soils and climates suitable for the growth of the coffee shrub—especially in reference to climate as influenced by elevation. At that early time large clearings had been made and coffee planted at Udagama on the Gindura river in the Galle District, which ultimately had to be abandoned. Mr. Butler, if not the first, was one of the earliest to demonstrate practically that an elevation not under 1,500 to 2,000 feet was necessary for successful cultivation, by opening land in Sabaragamuwa near Balangoda with success. It may be observed that in later years, preference was given to an ever-increasing elevation, as more and more forest was cleared,—experience showing that the

quality of the berry improved in proportion to the elevation within limits. After his Sabaragamuwa experience of jungle life, Mr. Butler became the planting partner in the firm of Acland, Boyd & Co., who were engaged in the largest planting operations of that decade in Ceylon. When it may be said that, besides the high roads to Galle, Kandy, Pussellawa, Matale, Kurunegala and a very few more, no other roads worthy the name existed in the planting districts, the physical endurance and perseverance of Mr. Butler and the enterprising pioneers who penetrated the remoter forests and selected lands for cultivation, may be, in some degree, estimated. Mr. Butler possessed the qualities we describe, in a high degree, and the result of his labours remain to this day in fine properties on the Knuckles range,—where he was about the earliest to select land—in Dumbara and in Dolosbage, which he selected and brought into cultivation with the aid of a small army of young men under his direction. It may be added here, that a number of the men who passed their early days in this valuable school, became successful planters and proprietors in later years. Roads to the new properties were a first necessity, and Mr. Butler was their pioneer. Some, like the Knuckles road, he traced himself; others were traced under his direction, which though improved and added to afterwards,

owed to him their initiative. The value of the work of men like Mr. Samuel Butler, the Shands in Sabaragamuwa and others, besides the labours of officials like Major Skinner and Captain Evatt of the Public Works Department in opening up the wilds of the interior, cannot be properly estimated at the present day. The difficulties in connection with Supplies, Labour, Money, Letters, &c. (money had to be brought up from Colombo to the estates in hard cash monthly) are now comparatively unknown; but in the days we speak of they sorely tried the patience and resources of hardworking men to overcome.

Reference to the *Government Gazette* in 1841, 1842 and 1843 would probably show a larger extent of acreage of land put up for sale and bought for planting purposes, than in almost any three years later, until we get to the rush of the "sixties" and "seventies." In the following years much plantation-grown coffee began to reach England from Ceylon, adding to very sufficient supplies from the West Indies, which had not then declined in production, as they afterwards did, under the combined influences of Slave Emancipation and Free Trade. All this seriously affected prices in the home market, and brought trouble to the many pioneers engaged in Ceylon, both to proprietors and to those whom they employed. There were exceptions, but almost universally, economy had been disregarded, and lavish and indiscriminating expenditure had prevailed, so that a crisis was approaching, in which many estates had to pass into other hands; and all property in the country depreciated. Mr. Butler was, we believe, the first Manager or Inspector of Estates to draw up and print a form of plantation accounts, on the basis of analysis of expenditure, which with variations became generally adopted. Mr. George Crabbe, of Messrs. A. & R. Crowe & Co., at that time being one of the first to call upon superintendents to curtail expenses on weeding; an item which, for want of analysis, covered extravagance in many other directions.

The labours of Mr. Butler as a planting manager were now soon to cease; the house of Messrs. Acland, Boyd & Co. came down in the commercial crash of 1847, and Mr. Butler had to pass through the troubles resulting from the insolvency of his firm. This to him proved to be a not unmix'd evil. With his usual energy, he accepted a Power of Attorney from Mr. J. P. Simpson, then leaving for England, whose sister he had recently married. This introduced him to an acquaintance with the Import trade of which he did not fail to take advantage when the time came. Mr. E. J. Darley, another partner of Messrs. Acland, Boyd & Co., had retired from the firm before the failure, and had gone to England, where he found the greater number of the proprietors for

whom the old firm had acted as agents, only too glad to place their estates in his charge. Returning to Ceylon Mr. Darley established himself as Darley & Co., but shortly joined by Mr. Butler he constituted the firm of Darley, Butler & Co. The new firm's business consisted chiefly of Estate Agency and Commissions. At this time Mr. Butler paid a visit to England, which proved to be an epoch in the future prosperity of the house. Forming a connection with the financial house of Matheson & Co., of London, a large Import business was commenced, to which was soon added equally large transactions in Ceylon produce. Shipping, both consigned and chartered, naturally followed. About this time was established their branch house at Cochin on the Western Coast of India, and ably conducted by Mr. Stephen Darley, brother of Mr. E. J. Darley, it proved a successful venture. Early in 1856, Mr. E. J. Darley, the senior partner, left Ceylon for a trip to England, which was lengthened out to three years, Mr. Butler conducting the business in the meantime; but falling into bad health, in 1858, under medical advice he went home in October of that year, Mr. Darley returning three months after. A short time before, the Governor Sir Henry Ward had placed Mr. Butler in the Legislative Council where his energetic character and abilities for business would soon have distinguished him, had not his departure for Europe, necessitated by ill-health, put a premature end to his career in that position.

This visit home proved to be a permanent stay, and also proved another important epoch in the fortunes of Messrs. Darley, Butler & Co., by the ultimate establishment of a house in London with the style of Darley & Butler. Mr. Darley, senior, returned to England about four years later, his son Edward being sent to Bombay to join Mr. Stewart of Manchester in establishing a branch there, while Mr. Stephen Darley returned to Colombo as partner with a chief assistant in Mr. W. W. Mitchell, who soon after became partner in the firm, with which he has been identified ever since. These were the years of the American Civil War and the consequent Manchester Cotton Famine. The firm, led by Mr. E. J. Darley, went boldly into the purchase of Tinnevelly cotton, both in the first and second years of the strife. These transactions resulted in handsome fortunes for themselves and their two partners, Messrs. Edward and Stephen Darley. The two latter shortly after left the firm, and Mr. Mitchell became the sole partner in Ceylon, both Messrs. Darley and Butler continuing in business in London. Early in 1870 Mr. Darley, senior, died, his share and capital passing out of the concern, and Mr.

Butler taking upon himself the responsibility conducted the London business, until his retirement in 1895. Mr. Butler's spirit of enterprise was not ended by the removal of Mr. Darley. On the failure of Messrs. A. and R. Crowe & Co. soon afterwards, his firm took over their premises and Cotton Agency at Tuticorin. After the cotton gains he purchased the estate of Combe Hay, near Bath, which he greatly improved with his usual thoroughness, at a considerable additional expense to the first cost of the property. He discovered a deposit of Fuller's-earth on the land, which when he came to sell the estate not very long before his death, assisted to break the fall in the value of land, which has taken place during the last twenty years. He was a Magistrate of the County of Somerset and a most energetic member of the Bench. Some years ago, he offered himself as Member of Parliament, but without success, for Chippenham and in the Liberal interest. His first wife died in 1887, and he married again in 1889, and soon after, accompanied by his wife paid a visit to Ceylon and India. He died after a short illness on the 27th September, 1893, aged 78, retaining all his faculties to the last.

Mr. Butler as a man of business was bold, enterprising and decisive, holding to the maxim "Nothing venture, nothing have." Generous by nature, liberal in business, reserved to strangers and even to intimates, but genial to his friends, he possessed in a marked degree commercial genius, sagacity and initiative, and a wonderful discernment of character.

We are indebted to a very old friend of Mr. Butler—one who had been a colleague with him in business in Ceylon in the early days—for the above interesting account of his career, written *currente calamo*, but which has required very little emendation at our hands. We observe only one notable omission, namely, the connection of Mr. Butler's nephew, Mr. Theodore Stretch, with the Colombo Firm thirty years ago, and the fact of Mr. Stretch returning home to join the London house where he is now sole representative of Messrs. Darley & Butler of London and Tuticorin. Mr. Butler left Ceylon before our day; but we were much struck during an interview in his London office, with Mr. Butler's grand physique even in his old age, with his continued interest in Ceylon affairs, and his thorough acquaintance with the development of the Colony. To Mr. Butler, more than to most men in our gallery of portraits, belongs the designation "Pioneer" in its most literal and honorable sense; for he contributed very largely to the raising of Ceylon from a military dependency to a great plantation settlement

and the first of Crown Colonies; while his whole planting and mercantile career was marked by unwearied perseverance, lively intelligence and strictest sense of probity. The name of Mr. Samuel Butler as Colonist, Planter and Merchant is one well worthy of being recorded in the annals of the Colony.

EDWARD J. DARLEY, MERCHANT:
1836-1869.

Although we have no portrait available, nor such facts as would be required for a regular memoir, still a few words may be permitted about Mr. Butler's partner—another old mercantile Colonist—Mr. Edward J. Darley. Mr. Darley came to Colombo originally in 1836, as a trained Assistant to the firm of Messrs. Acland, Boyd & Co., and the story of his starting on his own account on the failure of his employers, is narrated above; as also how he took Mr. Butler into partnership; but it is more fully related in the following communication from an old friend:—

"What can be said of Mr. E. J. Darley?—except that he was a good and kind man greatly respected and popular with all classes; industrious, painstaking and honourable in business. He was for many years a member of the Legislative Council in which capacity he was most useful. Mr. Darley came to Ceylon about 1836. He joined the firm of Acland, Boyd & Co., chiefly taking charge of Manchester Imports. He married a relative of Mr. Acland. He left Acland, Boyd & Co. in 1845 or 1846 and went home. The firm of Acland, Boyd & Co. failed in 1847, when the whole of the estates in which they were concerned and some others were placed in Mr. Darley's hands by the proprietors in London, whereupon he returned to Ceylon and established himself as Darley & Co. In the following year Mr. Samuel Butler joined him and the firm became Darley, Butler & Co. The new firm did not retain the agency of all the estate properties; but on Mr. Butler's return from a trip home at that period, there came to be a large accession of business in Imports with more than a corresponding Export and Shipping trade. Mr. Darley and his family went home again at the end of 1855, and returned at the end of 1858—in which year his partner left Ceylon for England not to return until lately when he paid a short visit to the island. The success of the firm was substantial from first to last, culminating in large gains in cotton in the years of the American Civil War. Mr. Darley finally left Ceylon during 1862, joining Mr. Butler in London as Darley & Butler. He never retired from business, but died in harness at the close of the year 1869 at East Sheen."

Mr. Darley always maintained the highest reputation, in Colombo, as a merchant of the old, reli-

able and regular, but tolerant and dignified school. We well recall during our first year in Colombo, the handsome figure, highly intellectual countenance and cool attire—dressed all in white even to the short “white jacket” now only seen at dinner time—of Mr. Edward Darley as he moved about the Fort during business hours. He had previously taken a prominent part in the Colombo Chamber of Commerce and served for a time in the Legislative Council. He was in somewhat close communication with the late Sir R. F. Morgan and A. M. Ferguson, all three being selected as his Executors by Dr. Christopher Elliott; and we know what a very high opinion was entertained by our “senior” then and always, of the probity, keen sense of honour and great shrewdness of Mr. Darley. After some 26 years of good work in Ceylon, Mr. Darley—having made his fortune by investments in Tinnelly cotton during the American War—finally retired to the old country, carrying with him the esteem and regard of all who knew him as essentially a useful Colonist, an honest merchant and a good man.

VII.

APHIDES, SCALE INSECTS, PLANT-BUGS, &c.

This tribe includes the Corn Aphis (*A. granaria*) which infests the young stems of corn and the growing wheat-ears; the green dolphin, as it is called, of the peas; the collier of the beans; the hop aphid, which in 1892 caused a loss of more than a million and a half pounds sterling to this country; the turnip and cabbage aphides; the black cherry-tree aphid, and many other kinds too numerous to name at present, besides the white cottony aphid of the beech, and the genus known as pine aphides, some of which are cottony, and some have a hairy covering. With regard to what we know at present of means of prevention, our best course is, if we can, to nip the evil in the bud by destroying the very first aphides that appear. This plan is constantly carried out in field management with regard to the bean aphid. When the colliers, as they are called from their black colour, appear on the tops of the bean shoots, these infested shoots are cut off. If the shoots and colliers on them are destroyed, the attack, or at least a great deal of it, will be stopped; but if, instead of carrying off the fragments and destroying them, they are only thrown on the ground, the black aphides will walk, or fly, back again to the growing beans, and the labour will have been in great part lost.

This same plan is useful throughout the summer for all plants or trees, such as apple, plum, cherry, or others, in which aphides, or green fly, as they are often called, collect in great numbers on shoots, which may be cut off without hurting the plant. Thus, if the shoots and aphides on them are properly destroyed at once, we get rid of centres from which attack is constantly spreading to do present harm. Also we may thus lessen the amount of next year's attack. It is the autumn brood of males, and females which provide the eggs to start the attack of the following year; and, therefore, anything which lessens the production of broods is

useful. The shoots, however, should always be destroyed at once, not merely thrown aside to wither gradually, whilst their infesting hordes gain wings to go home again. A healthy, yet not rank growth, is one great means of lessening the bad effects of aphid attack; as in the case of other insect attacks, the plant is thus supported through its troubles. But there is a further reason. It has been found that aphides come to maturity more rapidly when the plant growth is stunted, or the aphides themselves are so numerous, that it may be presumed the nature of the sap is different to that in the full flow of the healthy shoot, or the aphid is rather shortened of its food. Necessarily, maturity coming sooner, the successive broods are more rapidly produced, and the numbers greater.

Where we can tell with certainty that some species of aphid migrate at a special season, from one kind of plant or tree to another, we have a most serviceable method of prevention in our hands. It does not seem now to be open to doubt that a great part of the yearly attack of hop aphid, or “fly,” comes on the wing from sloe, damson, or plants of the plum tribe. This was long ago stated by German entomologists, and laid down by at least some of our hop-growers; and in 1884, after careful examination of specimens of aphides both from hop and plum, and reports from hop-growers (noted at length with figures in my Report for that year), I mentioned that there appeared to me to be reason to believe that the great attack, which usually occurs in the form of “fly” about the end of May, comes on the wing from damson and sloe, as well as from the hop.

In 1887, the late Professor Riley (Entomologist of the Department of Agriculture of the United States), set the matter of migration from plum to hop beyond doubt by his observations, of which a part was read before our own British Association; he stated that:—“*Thorodon humuli* hibernates in the winter egg state, this egg being fastened to the twigs (generally the previous year's growth) of different varieties and species of *Prunus*, both wild and cultivated.” From the winter egg Professor Riley found the female, the mother of the coming tribe, was hatched, the winged descendants of which female take flight to the plum. The existence of many generations on the hop, during summer, we are all well acquainted with; but during Professor Riley's stay in Europe, and more especially in England, he personally observed the point not previously worked out, of the autumn migration of the hop aphid, back from hop to plum, at the close of autumn. These observations, coming from such a high authority as Professor Riley, give thorough confirmation to the belief previously held as to migration; but still, I do not think that in this country the whole of the attack comes on the wing from plum, damson, or sloe, because (amongst other reasons) we have found aphides—that is, wingless females and lice—on hop as early as the end of March and the beginning of April, long before the attack coming on the wing made its appearance.

The hop aphides may be distinguished from the plum aphid, and from others of the *Aphidinae*, by the horns being hardly longer than the body, together with the lowest joint being toothed, or gibbous, and the tubercles on the forehead each having a strong tooth. The legs are short, and the honey-tubes long. Where there chance to be a large quantity of sloes, as, for instance, sloe hedges in the neighbourhood of hop-gardens, these at least might be got rid of without loss.

The number of remedies—such as solutions or mixtures of tobacco, paraffin, quassia, or other applications in the form of washings or syringings—are endless, and recipes are not given here, as these applications lie in the special province of the hop-grower. It may, however, be noted that sometimes washes fail in effect from the operator not being aware that in the case of many aphides the skin is covered with a kind of mealy coating, which throws off watery applications. Consequently, it often happens that unless the washing lodges amongst the aphides so as to kill them, or, again

the syringing is given with such force as to knock them from the plants, the insects are but little hurt. It is for this reason that soft-soap is so largely used, especially by hop-growers, for the washes: it is sticky, and thus adheres, in some degree, to the aphides; also it may be made the vehicle of any other application with which it may be desired to poison the aphides; and, thirdly, it is a good fertilizer, which, as we have observed, is important in aphid attack.

The great thing, however, that we need to know in order to check aphid attack, is where and how each kind spends the winter. Meanwhile, our best hope as to prevention lies in allowing as few shelters as possible on trees, or in neglected bark (in fruit or tree attack), or at the roots of wild grasses round fields, for possible shelter of grain aphid, and, generally, being alive to the necessity of not letting everything drift without thought of the reason how, or why, things happen; and, for remedy, in use of washes which are known to be suitable for the purpose in hand.

The woolly aphid, or American blight, is chiefly to be found in neglected orchards. The aphides shelter themselves for the most part in crevices of the bark, or where a bough has been injured, or under young bark healing over wounds; but they may be found on the young shoots, and the leaves, and are distinguishable by the white cottony material which surrounds them. I have also found this kind of attack on the rootlets. The piercing of the aphid-sucker causes the growth just below the bark to become swollen and pulpy; then the cells divide, and the bark above splits, and thus openings are formed, which give the aphides new hiding holes; and the diseased growth from their punctures is continued, until large tumour-like masses are formed, and the trees are very seriously injured.

The best method of checking attack is to keep the bark of the apple trees in such a healthy state—by means of proper pruning, the clearing away of injured branches, and useless and cracked bark (and other measures)—that there may be as few cracks and crannies, and half-healed spots, as possible, consequently, as little as possible of the shelter in which this aphid delights. Also, when the white wool in any nook or on any soft shoot in summer time, shows the presence of the pest, the shoots should be at once cut off, and some remedy should be well brushed or rubbed into infested nooks.

The number of different kinds of applications advised are almost beyond counting, though the principle throughout is one. But anything will be of use which will stifle or poison the aphides, without hurting the bark of the tree; and probably common soft-soap, or soft-soap with a little sulphur dissolved in it, or paraffin or tobacco-juice added to it, and well rubbed or washed in, so that it may be sure to reach the pests in their sheltering nooks, will answer as well, or better, than most of the many suggested applications. Some of the applications said to succeed should be applied (if at all) with great caution, or they may do more harm than good by soaking into the bark. Tar is especially to be suspected, for it is apt to melt in the heat of the sun; and turpentine, resin, and fish-oil, mixed and put on warm, and, in fact, anything that will thus choke the bark, is an unsafe application.

For attack below ground, the best treatment seems to be the clearing away of infested roots and soil round them, and drenching the spot well with soft-soap washings or drainings from stables.

The fifth tribe of aphides (the *Rhyzobiine*) feed mostly on grass-roots, and are wingless; should they be found troublesome, the use of the cultivator, plenty of gaslime, and similar measures, would probably clear them out.

It is exceedingly difficult to give any clear view of aphid life, or means of prevention, for few are known, excepting in cases where the plants are under cover, and where, therefore, fumigation can

be brought to bear. But the principle throughout appears to be this:—Check attack by diminishing lurking-places, and also by pruning off and destroying infested shoots and parts of plants, or infested leaves (as with cabbage), as much as you can; and where you can bring washes to bear, use soft-soap as a foundation; but where the application may be run into the ground, and thus remain round the insects, ammoniacal water, or drainings from stables, lime-water, or other drenchings poisonous to insect-life, and that will not hurt the plant, have proved useful.

The "scale insects" are the third section of the *Homoptera*. These insects do great harm by drawing away the sap by means of their suckers. There are many kinds, differing in various points of structure, as well as form; but in the case of the apple mussel scale which is sometimes very hurtful in orchards, this shell-like husk, which is in shape like a minute mussel-shell, adheres firmly to the bark during winter; and under it, but not attached to it, there lies the dead body of the female scale, and fifty or more eggs. In spring these hatch, and from them come small white flat insects, furnished with eyes, horns, six legs, and a sucker. These are very active at first; but presently each scale larva runs its sucker into some spot it can pierce, begins to feed, and ceases to move. A secretion of waxy material takes place on its back, beneath which the scale forms; and after various moults, and additions by secretion to the size of the scale, the change of the insect under it takes place to the perfect state. This, in the female, is to a shape like that of a globular flattened maggot, greenish in colour, without joint limbs, which lays eggs and dies. The males (I believe, in the present case, first observed not long ago by Prof. Riley) have one pair of whitish wings, and no proboscis.

The best method of getting rid of these scales is to prune off infested boughs, where this can be done. Where it cannot, rubbing off the scales by means of cloths or brushes, after moistening the bark with water, or scraping them away with a knife, gets rid of many; and, generally, the same kind of remedies are useful as are applied for American blight, such as soft-soap, with some mixture of paraffin, kerosine, or other addition, which may stifle the scale insects which have been disturbed, and make the bark unsuitable for attack.

The order of plant bugs includes both plant and water insects, which may be known by a kind of leathery patch at the base of the front wing, "dis-similar" from the rest of the substance, whence the order takes its name of *Heteroptera*, or "dis-similar-winged." The long-legged insects known as water measures, which we see skimming about on the surface of ponds, and the water boatmen, which by the help of their long oar-like front legs sweep through the water like insect skiffs, are common examples of the water frequenters of this division.

The plant bugs sometimes do harm by sucking the juices of plants, especially by *Lycophotus solani*, which attacks potatoes; but they are, so far as I am aware, rarely injurious in this country to any serious extent. Some kinds, of a longer narrower shape, are to be found on wheat and barley. The wheat bug (*Miris tritici*) has also often been found on grass in marshes; the barley bug (*M. dolabratus*) is exceedingly common in barley, and on flowers of grass near.

Some of these various out-of-door bugs probably do good, by means of their carnivorous habits; and with regard to the wingless kind, which, to our misfortune, occasionally teaches us that feeding on animal juices, by means of a sucker, is a characteristic of this order, I think we need not enter on its prevention here.

The remaining order is that of the thrips, *Thysanoptera*. These are very small insects, which sometimes do much harm to corn. They are

nearly alike in shape in all their stages, but they are scarcely large enough to be seen by the naked eye.

The perfect insect of the corn thrips is blackish, but in the first state of larva or grub it is of a deep yellow; in the second it is of a paler yellow, with whitish wing-cases. These thrips are to be found from June onwards in the growing wheat ears, and sometimes in the sheathing leaves of the stem. They feed on the corn grain, by piercing into it with their sucker-like jaw apparatus, and thus draw away the juices and cause the grain to shrivel.

Another kind infests the potato, drawing away the juices in the same way as the corn thrips; as do also the aphides, scale insects, plant bugs, and some others, which we have just noticed, with their variously formed sucking apparatus. In the case of the potato thrips, dusting with dressings of lime and soot, or other mixtures, might do good; but for the corn thrips it seems impossible to find any application, as any of those used to destroy the thrips would hurt the corn. The chief means of prevention seems to lie in clearing stubble or in deep ploughing to get rid of thrips which may, be wintering at the roots of the removed crop, or in destroying wild grasses on which the eggs may be laid round the fields.

The knapsack sprayer is a very convenient form, and is noted here as being serviceable for distribution of washes and sprays for destruction of aphides, scale insects, &c.; as well as for the distribution of Paris-green, mentioned previously.

A CEYLON PLANTER IN GERMAN EAST AFRICA.

THE CLIMATE—FEVER—LEAF DISEASE.

I was tired of Ceylon, and got an offer of a good billet in German East Africa, and being told the climate and shikar were good, I jumped at it. The climate is rather warm in the plains, and delightful in the hills; until you stir up the soil, when it's fearfully feverish: pucca black-water fever. And as I came out as a planter, the results were inevitable. First thing I had to do was to drain out a lot of swamps, which was something like cleaning out cesspools. The planters are mostly Germans of sorts. One was a very decent chap, rest were an awful lot of bounders. A brother Englishman made me a trifle ashamed of my nationality. I landed at Tanga on the coast in October, 1893. Lovely harbour, Tanga, land-locked on 3½ sides, large enough to float ships of 4,000 tons at present. I marched up country: took me 2½ days in the very long marches of 20-30 miles a day.

First thing I did after planting up a ten-acre patch was to go down with fever for a fortnight. I got better, and the other Englishman on the tote had a row with the Javanese labour and left for the coast. I couldn't speak a word of the language, but quickly gathered they thirsted for the other man's blood. The plantation was only 90 acres planted, 50 more ready to plant, and at the end of the year we got it up to 350 planted. The "reserve" was a block of 275,000 acres. Lots of room for extension. All coffee, except two acres of wretched tea. Grew lots of native food, arrow-root and so on for estate consumption. Leaf disease first appeared some three months after I arrived, on the oldest coffee, about 15 months' old. Started on one or two trees, and I promptly spotted it and reported it to my boss and in fact the whole district. No one believed it at first and said I was drivelling. I burnt the affected trees at once, and sent specimens of the leaves to Kew and Berlin. Before we could get an answer, the pest had increased to such an extent that confirmation of my surmises was no longer needed. On making enquiries I find that the seed had been purchased in Colombo by the German Consul. It was reported that he bought the seed ignorant that it was to be used for planting. Ten per cent. at least was light. Of the balance only about 30-40

per cent. came up fairly strong plants. The best of these were planted out, with the above result.

The course of the disease ran curiously. It took a strip away from the lines right down a field. Then it worked back over a ridge through a break in the wind belt to another clearing, where there were two very large nurseries. There it played mischief with. These plants were put out and the whole estate got affected. I left before the full results could be seen, but I noticed the only unattacked portions were some line coffee and a little bit of a shade clearing. Nearly all the rest of the coffee was in the open, pucca Ceylon style, barring a few odd trees some 40 to 60 feet apart, that were only left because they were too big and expensive to cut down.—*Planting Opinion.*

COFFEE PLANTING IN NYASSALAND.

FROM AN INTERVIEW WITH MR. G. M. CRABBE.

Mlanji is fifty miles from Blantyre, and is situated on a plateau at an elevation which rises to 3,000 feet, though the Nyassaland Coffee Company's place is only from 1,500 to 1,800 feet high. This plateau is overlooked by Mlanji mountain, which rises to 10,000 feet. The country is undulating, like the Assan district, and it has a rainfall of about eighty. The temperature is cool and equable, but the place is particularly unhealthy from the middle of November to the end of February, which is the planting season. The pioneer of Mlanji is Mr. Henry Brown, who was formerly an Inspector in the Ceylon Police. When he left here, in 1890 or 1891, he went to Central Africa in connection with the work proceeding at the Lakes; but in a short time he took to coffee planting.

Mr. Crabbe said: "Well, when I left the Company's property they had 240 acres opened, and last year they opened another ten acres, making 250 acres opened, but another 250 is to be opened this year. The jungle which has to be cleared is very heavy, but the soil is by a long way the best soil that can be found there, and is very dark-red in colour. My place has been taken by Mr. Moggridge, who was formerly with Mr. Cotton, on Demeira, Passara. He has with him as assistant Mr. Robin, who also hails from Ceylon, having been a planter with Mr. Metcalfe in Punduloya. They came out to me a year ago last May. Robins has suffered very badly with fever. Five miles off our place was an estate belonging to Mr. Moir, who was formerly Manager of the African Lakes Company. He had about 180 acres opened in coffee. On the other side of us our nearest neighbour was Mr. Henry Brown, who had about 200 acres opened. He had some coffee in full bearing, and he had also a few tea-bushes, but they were not a good job. Then about ten miles off us Mr. Bradshaw had about 180 acres. His was a very good place. His oldest coffee was about five years of age, and he got a crop of 30 tons last year. He has just left on a trip home, but he has certainly done the best of anybody there. Then, there is a small estate of 60 acres belonging to a Mr. Simpson, who, in addition to coffee, has gone in for a few native products. I think that is about all. Of course there are a good many plantations round about Blantyre; but with the exception of the Buchanans' property which is managed by Mr. Hunter, they are all small holdings. There are no factories, and all the pulpers are worked by hand with the exception of those at Mr. Moir's place. He has the only water-wheel in the country."

But the great thing they have to contend against, is the want of good seed. Of course, the coffee is of the Arabian sort, but this want is greatly felt, and something will have to be done with regard to getting better seed. The Nyassaland Coffee Company did try to introduce Brazilian seed, but it didn't answer—it failed to germinate. All the seed we had was what we got locally. No coffee seed from India or Ceylon, you know, is allowed into the country on account of leaf disease, nor is tea seed allowed, though some sent by Mr. Carson from Ceylon managed to get in and it turned out a failure

It was Indian seed; but it got in as the Commissioner at that time was anxious it should be started. The coffee is planted under shade there."

"Then the administration seem to have done very little for the country up to date,—I mean as far as helping the planter goes. There is a great want of roads and transport facilities. We sent all produce to Chiromo on the river Zambesi. That is 70 miles away, and all the produce had to go down on niggers' heads as, though there was a river near us, and it led to Chiromo, it was not navigable. From Chiromo our produce went to Chinde; Beira, of course, being the port of export. There were two steamer lines which took our produce away, namely, the German East African line, which goes by way of Aden, and Rennie's line, which runs south round the Cape direct home, and which took the bulk of what we sent. The steamers of these lines call alternately once a fortnight. But Beira is just the same primitive place it always was. Not a single thing has been done in the way of making proper warehouses there, and what is exported and what is imported lies about on the shore till removed, and is exposed to all sorts of weather.

"Labour is plentiful. At least it is plentiful with the exception of the four wet months. That time the natives mostly employ in working their own gardens. A lot of the labour comes from Lake Nyassa, the people coming down a distance of over 200 miles. We sent Kanganies to recruit them, and when we got the labourers we paid them, in calico, three shillings a month, so they were cheap. The local labourers only got two shillings' worth of calico a month. We had no trouble either with advances or tendus. The language spoken in Mananga, it is very easy to learn, and all of us spoke it. The Angonis are the best labourers, and when we got them we had to get the Mananga language interpreted, but that was generally easily managed. The great want was native artisan.—"Local Times."

COFFEE-GROWING.

C. SKELTON.

My attention having been drawn to a paragraph advertising to a sample of coffee having been forwarded to the Department of Agriculture from the Clarence River district, as an ex-Ceylon coffee-planter, I felt interested in the fact that coffee could be produced in New South Wales, and called upon Mr. W. S. Campbell—of the Department—who was kind enough to show me the sample, which though only partly cured, being in the "parchment"—which, together with the silver skin having to be removed before it would be considered a marketable commodity—goes to prove that a fair quality of coffee can be grown in the Colony. The bean seems full, and of a tolerably good colour; so far as I can judge it would fetch from 65s. to 70s. per cwt. in the London market; were it cured in "plantation style" it might realize from 20 to 25 per cent. more. The question to be solved is, what yield per acre can be obtained from the plant in the latitude of the district where the sample was produced, for coffee is indubitably a tropical product and requires plenty of heat and moisture. What I am afraid will be found most detrimental to the success of coffee in this Colony are the frosts that even in the most northerly parts of the Colony are occasionally experienced. In Ceylon I once saw a field of coffee killed right out by one night's slight frost; it was at a very high altitude, about 5,000 feet, and it must have been of very rare occurrence, for the trees were ten or twelve years old when they were bitten. However, if that difficulty can be surmounted and labour obtained at a reasonable figure, the coffee would have to yield from 50 to 60 bushels of "cherry" coffee per acre—equal to about 6 cwt. per acre, or about $\frac{1}{2}$ lb. of clean coffee per tree—to pay working expenses and leave a fair profit.

To the intending planter a few hints from one with seventeen years' experience at coffee-growing

may not be amiss. Choose, if possible, land naturally drained, a gentle slope is preferable, so that surface water will not lie and sour the soil. Good friable soil, of course, is a desideratum, it need not necessarily be very deep, as coffee is a surface feeder. Avoid cold, wet clay sub-soil, as immediately the tap root reaches such a subsoil the tree will be observed to decline and ultimately die of what Ceylon planters used to technically term "wet feet"; the only cure for it is sub-soil draining, and that runs into a lot of money. The land obtained, the next thing is to make a nursery. Clear a piece, sufficient to raise plants for the area you intend to open, which, planted at 6 feet by 6 feet, runs to about 1,200 plants to the acre. Trench the ground and lay it out in beds, as you would a vegetable garden. Procure some coffee in the "cherry"—a bushel of cherry coffee will yield somewhere about 30,000 seeds, sufficient to plant about 25 acres—and pulp it by squeezing between the fingers, plant the seeds in the prepared beds 9 inches by 9 inches apart, with just a covering of earth over them. Water every morning and evening, unless it rains, and continue to do so until the plants are 3 or 4 inches above ground, and afterwards, should the weather be dry, give them a good watering every alternate evening or so. Meantime, while the plants in the nursery are coming on, your land is supposed to be in process of being cleared. Let the logs that have not been consumed by the fire remain on the ground; stumping also is unnecessary, as there is no ploughing to be done. Get some thousands of pegs cut, about 15 inches long; with these and a lining rope (an ordinary clothes line will answer), marked at every 6 feet with a piece of rag, or something let into the twist, proceed to mark off your ground in parallel lines 6 feet apart. Keep your lines as straight as possible by using three ranging rods, or wadd sticks, as they are usually called here. You will find the benefit of having your trees in straight lines afterwards in working the place; besides, nothing looks so bad as an irregularly lined field of coffee. It may sometimes be found necessary to cut or roll a log out of the way in order to get the peg in its proper place. When all the lining is done proceed to dig a hole 18 inches deep, by the same in width, at each peg, leaving all the soil dug out in a heap at the lower side of the hole. Scrape all the surface soil and ashes left from the burning off into the hole till it is heaped up, as it will sink considerably, then stick back the peg into the heap to mark the hole. After the holing and filling in is finished, seize the opportunity of the first wet weather to plant out your nursery plants, which, we will suppose, are now five or six months old, as it will take about that time to prepare the land for their reception. Lift each alternate plant, either by pulling them up and carrying them out to the field in bundles, or, if you have time and labour to spare, lifting each with a ball of earth at the root and taking them out to the field on trays of some sort. The latter way is the best when it can be done, but if you have a large field of 80 or 100 acres to plant up it takes a lot more labour to do it. Be sure not to put the plant in too deep, but only to the same depth that it stood in the nursery; it is a mistake that is often made to plant too deep, the leaves grow yellow and the plant seems strangled, and often takes a long time to recover. It is a good plan to put the plant in a little deeper than you intend to leave it, place the earth round the roots, then stand with a foot on each side, and give the plant a steady, gentle pull upwards—that brings all the roots straight. If you have favourable weather probably most of your plants will come on all right, but there are sure to be some failures, and filling up vacancies with the plants left in the nursery should be carried on at every opportunity, that is whenever you have wet weather. Planting completed, there is nothing much to be done except keeping the place clear of weeds, cutting any roads or drains that may be found necessary, and erecting some sort of temporary house accommodation for self and labourers; which should be of the cheapest, until such time as you can see

how things are going to "pan out." In eighteen or twenty months the plants will have grown sufficiently high to be topped—that is, cutting the top off the plant at 3 ft. 6 in. or 4 feet, according to soil and aspect, if at all exposed to wind the former height is the best. Topping has the effect of making the tree spread out laterally, covering the ground from the sun, thus tending to prevent the growth of weeds, besides facilitating the gathering of the crop. Trees grown in the "native" style—namely, allowed to grow to their full height, never bear more than half the crop they otherwise do, having so much useless old wood to sustain, besides the difficulty of gathering crop from branches 8 or 10 feet from the ground. In the third year the "maiden," or first crop—generally amounting to 2 or 3 cwt. per acre—may be expected, and preparations accordingly will have to be made for it by erecting the necessary pulping-house, store, and platforms for drying the coffee upon, purchase of machinery, &c. I may here state that in selecting a site for the works it is absolutely necessary to fix upon one to which it is possible to lead a stream of water, and if practicable, sufficient to drive a water-wheel, which will be found a very great convenience and saving of labour; in fact, if any considerable area is to be put under coffee it will be found almost impossible to get through the work without one; in any case water is indispensable for pulping and washing the crop. To give directions for the erection of the necessary works, to be of any practical use, is scarcely within the scope of an article of this sort. Illustrative diagrams would have to be given and the most minute details entered into to make it intelligible to the ordinary understanding. Messrs. John Walker & Co., Bogambra Mills, Kandy, Ceylon, supply all the machinery necessary on coffee plantations, and if applied to, I have no doubt will be glad to forward price lists. A Walker's disc palper, sufficient for the crop to be obtained off 25 or 30 acres of coffee, can be purchased for about £15; laid down in this Colony for about £17 10s. In Ceylon and Southern India the usual estimate for bringing coffee into bearing was £10 per acre; that embraces felling, clearing, planting, and general maintenance till the coffee begins to yield returns, namely, in the third year after planting. As previously stated the first or "maiden" crop is usually from 2 to 3 cwt. per acre; it goes on increasing up to the sixth year, when the tree is supposed to be in full bearing, when with good soil and favourable seasons it may yield 10, 12, or even 15 cwt. per acre. Under these circumstances it is not difficult to see

how paying a speculation coffee-growing is, with annual working expenses at £8 or £10 per acre, and London ruling prices for "plantation" coffee at 100s., and sometimes over that, per cwt. Unfortunately, results do not always come up to expectations; the coffee planter, like the farmer, has many difficulties to contend with, white bug and black bug, too much wet or too much dry weather, scarcity of labour at critical times when he most requires it, and, sometimes, that which is worst of all, scarcity of money. However, taking it all in all, a little discomfort and hard work is easily borne when there is a prospect of making a competency, of which I do not think there can be much doubt should judgment and care be exercised. It is as easy to lose money at coffee as it is at almost anything else with a reckless hand at the helm.—*Agricultural Gazette.*

THE DIMENSIONS OF TREES.

In our last issue we called attention to some trees, of extraordinary dimensions, recorded in Kerner and Oliver's *Natural History of Plants*: we now add some notes of measurements of large trees of Indian species which may be of interest.

Cedrus Deodara.—A section of a Deodar tree from the Jaunsar forest in the Forest School museum measures 27 feet in girth and shows 655 annual rings.

Cupressus torulosa.—Brandis' Forest flora mentions a cyprus tree measured by Dr. Steward which was 27 feet in girth near the ground.

Tectona grandis.—Teak trees of enormous size are not infrequent in Upper Burmah. A felled log in the Yamethin forest measured by S. Carr was 64 feet long and 13 feet 9 inches in mean girth; it was perfectly sound, and, when found, was in process of being split up to build a Buddhist monastery. In the Myittha—Paulanug forest there are two immense teak trees standing side by side, the largest of which was found by H. Calthrop to be 20 feet in girth at 6 feet from the ground with a height 60 ft. to the first branch; and at Alaungdaw-Kathaba in the Chindwin a tree measured by C. E. Murid girthed 17 feet 4 inches at 5 feet from the ground.

Bombax Malabaricum.—We have a photograph of a tree said to be 87½ feet in girth one foot from the ground, but it is believed that the measurement was taken along the contour of the buttresses.

Santalum album.—As a record measurement of a tree of the smaller classes may be mentioned a sandal tree felled by A. E. Lawrie in Coorg which measured 5 feet 6 inches at 5 feet from the ground.—*Indian Forester.*

TRADE OF INDIA : 1896-97.

As we anticipated, a recent post has brought us from the Government of India, a copy of the "Accounts relating to the Trade and Navigation of British India for the month of March 1897, and for the Twelve Months, 1st April 1896 to 31st March 1897, compared with the corresponding period of the years 1894-95 and 1895-96." This is a bulky, but handy-sized statistical return of 118 pages giving full details of all the Import and Export Trade of India for the year ending with March last; and yet the press and merchants of Colombo have not yet (at end of May) got the local Customs Accounts for the year ending 31st December last. We quote the grand totals of the Trade of India :—

	FOREIGN TRADE.		
	1894-95. R	1895-96. R	1896-97. R
IMPORTS.—Total Merchandise..	725,239,926	729,367,533	762,158,352
Total Treasure..	95,812,073	133,679,854	130,845,635
Grand Total of Imports ..	831,101,999	863,047,387	893,003,987
EXPORTS. Foreign Goods ..	50,574,144	47,175,159	40,336,372
Indian Produce and Manufacture ..	1,037,575,846	1,095,456,241	998,801,824

Grand Total for Exports ..	1,171,398,499	1,185,945,489	1,089,211,139
Grand Amount of Import Duty collected, including Salt ..	54,368,245	65,743,137	61,390,392
Ditto, Export Duty Collected ..	9,034,881	9,292,242	7,525,600

We shall discuss some of the details very soon.

DESICCATING MILLS.

A Marawila correspondent writes :—

The Superintendent and Engineer of the Veyangoda Desiccating Mills were here some time ago prospecting for a site it was said to start Desiccating Mills. They fixed on a spot at Kudaveva near the 42nd mile on the old road bordering the canal. The more mills the merrier for estate proprietors.

CURIOUS PRECIOUS STONES.

A Bangalore Correspondent sends us the following interesting communication :—

"In your issue of the 20th April para 3, particulars regarding a star sapphire from Ceylon are giving at some length. Several royal personages, whose names are mentioned have seen this gem—which is now on view in London—between two lighted candles. The stone is said to be worth several thousands of pounds. I have got a star sapphire, set in a large gold ring, and I wish it were worth even a few hundreds of pounds. Nevertheless if the stone is held between two lighted candles, it likewise shows 3 separate stars with rays; but in any other light only one star is visible; but embellished with 6 rays. If the

stone is held some distance from the eyes with the sun shining upon it, the star will appear to advantage, in fact much more distinct than if looked at in any room, but between two lighted candles in the day-time the stars are brought prominently out even when held quite close to the eyes. Such being the case, the stone is certainly an uncommon one. Evidently the London jeweller knew what he was about when exhibiting the gem between two lights. Many years ago the great jewellers, P. Orr. and Sons, of Madras, advertised in the Madras papers a star sapphire for sale. The advertisement was intended for Rajahs and capitalists, and it must have been a beautiful gem or it would not have been so advertised. I do not know who purchased the stone, but after reading your paper regarding the one now in London, it struck me that it might be the same stone, and that the exhibiting of it between two lighted candles with the result shown was in all probability a new discovery.

"I have probably the best cat's-eye stone in Southern India. It is set in a large gold ring, and it has been in my possession for a quarter of a century. I purchased it from Agurchand, the rich Madras Sowcar who died a few years ago. It is nearly as large as the human eye, and in some lights—say in a small room with windows all around it, no less than 6 opalescent rays are visible. In a room with fewer windows, 3 or 4 rays are visible. A few years ago particulars of a large cat's-eye stone were given, that was on show at the Melbourne Exhibition. I read accounts of it in the Madras papers. It was the property of a Ceylon merchant, who wanted £3,000 for it, and it was stated that the Governor of the colony, whose name was mentioned, had offered £2,000, but his offer was refused. It was also said that it was the only stone in the world that had 4 or 5 opalescent rays in it, but this statement was untrue. My cat's-eye stone is evidence to the contrary. Dealers in these gems say that the more opalescent rays there are in a specimen, the more luminous will be the single ray observable in the stone when examined with the sun shining upon it. This is no doubt correct. For my stone is worth looking at when the sun is shining straight down upon it,—when the single ray in the centre of the stone appears alive with light, and is something to be remembered. Many years ago I sent it to London with a gentleman who is now in this country and who was going home on six months' leave. I did this at the suggestion of Surgeon-General Furnell and Surgeon-Major Luke Hackett, who were much interested in precious stones and who were anxious to know what the London jewellers would value it at, and in two of the largest shops in that great city the same valuation was given, viz., £100, and good cat's-eye stones have risen in value since. I examined the stone yesterday, between two lighted candles, simply out of curiosity, when two well-defined and luminous opalescent rays appeared. The distance between each ray was about one quarter of an inch, and the sight was worth seeing. Of course at any time of the day and in any room with daylight in it the stone is worth looking at. I am convinced that this gem was once worn in the earring of an idol in some temple, as there is a gold pin running through the bottom of it, and this drilling of the stone would not have been done for any other purpose than the wearing of it in an earring, but the gold pin is not visible except on close inspection; and this reminds me that the Orloff diamond served as the eye of an

idol in a Trichinopoly temple, and was stolen by a French soldier who sold it to the captain of a ship for 50 rupees. It then passed into the hands of a German Jew, who paid, I think, £4,000 for it, but the Jew knew what he was about, as he sold the stone to the Empress Catherine of Russia for £80,000, an annuity of £8,000, and a title of nobility. I could have sold my cat's-eye ring many times had I wanted to part with it, for it has been seen by many officers, both Civil and Military, of high rank, and it was always very much admired. It would make a handsome brooch stone, if surrounded by diamonds, rubies, or emeralds, and would then grace the neck of the fairest lady. I have had in my possession many years a very good fire opal. It is set in a massive gold ring, nearly all the colours of the rainbow are visible in this stone. A large spot of red is often seen in it of such brightness that to look at it is like looking into a furnace, the colour is so vivid. This gem has also been much admired by many people, and a District Sessions Judge some years ago was anxious to become its possessor. I applied the two lighted candle test to this stone also, and the different colours that came out by simply changing the position of the stone by a slight turn of the fingers was something marvellous, and brought back to memory what I had read of the fire opal the size of a hazel nut, that Nonnius, the Roman Senator, had in his possession. It was valued at 50,000 sesterces, and rather than part with his gem to the Emperor, he suffered exile, and took his beautiful opal with him. A rich lady, the wife of a gallant officer of Cavalry, who was in this station last year, had in her possession a very large fire opal—something really worth looking at, and worth having also; for a Delhi jeweller, who was at this station for a short time, offered 15,000 rupees for it, but the offer was not accepted. I have a small cat's-eye stone set in a gold ring that will give two opalescent rays. The little gem is worth looking at, and is of nearly the same colour as one belonging to a gallant colonel, now in Madras which he wears set in a scarf pin surrounded with small diamonds. I saw this stone a few years ago, and was told by the Colonel that he got it direct from England and gave £75 for it. Alexandrite is not a very common stone. I have got a well cut one that was brought from Ceylon. It is a dark green stone, but will turn of a red colour from reflected light; the light from a lucifer match is sufficient for the purpose. The stone was named Alexandrite after Alexandra the Princess of Wales, and is only a recent discovery. I saw a very large uncut one some years ago in Madras. It was shown me by Streeter's agent, who was spending his Xmas holidays that year with a friend of mine a few years ago. I read in the English papers that the Maharajah Dhuleep Singh had purchased in London some handsome opals as a present to his mother, as there were no opals in India. I could have told Dhuleep Singh whom I had seen in this country when he was a boy, that he was under a wrong impression, for opals are found in India, for I picked up a very good one in the Nirmul Jungle in Feb. 1858, which I gave to Capt. Robinson who commanded my company as something that would remind him in after years of the long march the regiment had during the Mutiny from Madras to Calpee. During the Mutiny I purchased a few stones of Banda, Kirwee, Sangor, and other places, but of no particular value, except a few rubies at Saugor for two officers of

the regiment. Some beautiful moss agates, onyx, sardonyx, carbuncles, topazes and other stones I came across. Some of them are real curios. I have in my possession a large piece of stone so ugly that no one would ever think of picking it up. Yet, nevertheless, it is really worth having, as a half score of brooch stones and a score of finger ring stones could be cut from it; the polish it takes, and the beautiful colours in it then come grandly out. It is probably a blood stone, but the blood stones seen in rings are nothing in comparison either in richness or colour to the ugly looking treasure I have. I have all sorts of corundum, but the greatest curio is a ruby corundum 4 inches long, hexagonal, or six-sided (the true formation) and weighing over two pounds. This is no doubt the largest ruby, not a crystal ever found, and it will take a fairly good polish of a cloudy ruby colour. If it was a pure crystal it would be worth millions of pounds. The weight of this stone would not be credited by anyone not knowing the relative weight of the different kinds of precious stones. Probably the best judge of precious stones in England has stated that he has seen £1,000 paid for a good cat's-eye ring stone. Some jewels were sold lately at the Mysore Palace and 4 cat's-eye stones were sold for 8,000 rupees by a jeweller from Bombay. An engineer officer who saw the stones spoke anything but in praise of them at the trial of Mr. Jacobs, at Secunderabad (the great diamond case). I read in the Madras papers that he had two cat's-eye rings on his fingers when in court which were much admired by those present. One of these stones was valued at 8,000 rupees. Nearly all large diamonds have eventful histories. The Kohinoor (mountain of light) now worn by Her Most Gracious Majesty the Queen-Empress has a wonderful history, so has the Pitt or Regent diamond. Pope in his Man of Ross, I think, would lead his readers to believe that it was stolen by Mr. Pitt when Governor of Madras:

"Asleep and naked as the Indian lay
An honest factor stole the gem away."

Mr. Pitt wrote at length to prove the accusation false, stating that he had purchased the stone from one Helmachund, and mentioning the number of pagodas he paid for it; the purchase nevertheless was a profitable one for he sold the stone to the Regent Duke of Orleans for £120,000, and it was worn afterwards by the Emperor Napoleon in the pommel of his sword. The De Farcy diamond has probably the most wonderful history, as it was the property of King Charles of Sweden, and he had it with him at the battle of Pultowa, where he was killed. Afterwards John De Barley, Count De Farcy, became its possessor, and he sent it as a present to the king, but the mounted servant to whom it was entrusted was attacked by robbers and killed; the diamond, however, was recovered, the faithful servant having swallowed it. The largest diamond in the world belongs to the Rajah of Borneo; it is uncut and in shape like a pear. There have been large sums offered for this stone, especially by the Dutch, but the Rajah will not part with it, as it is a treasure mine to him. Water is put into a small hole at the top of the stone and the people of Borneo believe that the touching of this water with the finger and putting a drop to the forehead will cure the worst diseases. In this belief all those who can afford it try this water cure. A very rich man could, if he wished buy a small basketful of diamonds from 4 to 8 carats weight each but he could not buy a basketful of rubies or

good cat's-eyes; for these stones, of good quality, are not procurable in the market, and it is almost an impossibility to buy a large emerald, as a large one free from flaws is rarely met with. The largest ruby in the world is not much larger than the egg of a pigeon."

Our correspondent's letter is apparently not written in a purely literary spirit, for at the end he asks us to add that lovers of gems and curios who may wish to purchase the stones described by him are invited to address him on the subject. The communication, notwithstanding that it is a sort of catalogue of his wares, is, however, interesting, so we are not unwilling to do what he requests, and forward him any letters that may be addressed to him at our office under the initial "T." We know more of our correspondent than his name and address.—*M. Times*, April 29.

CEYLON TEA IN THE STATES.

Mr. Kenyon Parsons writing to our contemporary says:—

"Since Mr. McKenzie has taken up the work of pushing teas here there has been a great desire on the part of the trade to pay attention to Ceylon Teas. This is owing I am convinced to the way Mr. McKenzie has advertised the tea in the trade papers, and I may say also in the magazines and periodicals. The expenditure of money in this direction is just beginning to make itself felt, and if it were stopped now, it would be equivalent to throwing seven-eighths of the money spent in advertising away. The value of advertising is in proportion to the length of time you advertise. Every year will show a greater return over the previous year, and to stop now, would be like, after you have cleared and planted up an estate to withdraw your labor, and let the tea plants grow up as best they could, and though I have not had the pleasure of meeting Mr. McKenzie, I think the thanks of all interested in Ceylon tea are due him. To my mind the best way to push tea in this market is to advertise in the trade papers and a few magazines as Mr. McKenzie is doing now. You will find that the trade will take hold of the tea. It is the 'trade' you wish to get."

This most fully confirms the view we have held all along as to the greater value of advertising—rather than of subsidising.

AMERICAN NATIONAL BOARD OF TEA EXPERTS.

The American Government is determined to secure the purity of the tea imported into the States, and having passed a law on the subject, it now follows this up in the following practical way:—

The Secretary of the Treasury has appointed A. P. Upham and E. A. Schoyer, of Chicago; Herbert G. Woodworth, of Boston; T. A. Phelan and W. P. Roome, of New York; Andrew P. Irwin, of Philadelphia, and Robert B. Bain, of San Francisco, as a Board of Tea Experts, under the act of March 2, 1897, to prevent the import of impure and unwholesome tea into the United States. The Board has held several meetings at the Appraiser's stores, and is gathering information and seeking aid in order to fix a satisfactory standard. A report has been submitted to the Secretary of the Treasury, which states that the Board has selected such standards as, in its opinion, will represent the intention of the bill regarding purity, quality and fitness for consumption. The reports adds:—

The Board recommends, first, that the comparison of standards with teas delivered shall be made not only with regard to flavor, but particularly with regard to the appearance of the leaf after infusion.

In color of infused leaf and in freedom from admixture with black and decayed leaf all teas should be equal to the standards, but any consideration of the make or so-called style of the dry leaf should be omitted. The leaf of the infusion must equal the standard in freedom from scum, gritty substance and leaf made up of dust and congee (*i.e.*, rice paste). The Board further recommends that your Department issue instructions that all teas shall be labeled with their proper trade names, so as to avoid palpable fraud in the use of false labels. The importance of this point has been pressed upon it by the trade, and it cannot too strongly emphasize it, particularly referring to green teas, of which the Pingsuey kinds have been heretofore labeled Moyune, the former being an inferior and the latter a superior tea. The Board therefore respectfully urges upon you as of supreme importance that the examiners should be not only thoroughly honest and trustworthy, but also experts in tea. That the present incumbents at New York and Chicago meet these requirements the Board has no question, but as the examiner at San Francisco is not an expert in teas, but a chemist having insufficient knowledge of the article, it is absolutely necessary that a person possessing the proper qualifications should be appointed at that port

AN AERMOTOR FOR COLOMBO.

The first of the variety of wind mills known as Aermotors in Colombo has just been erected at Devon House by Messrs. W. H. Davies & Co. It is a wheel of 8 feet diameter, made of galvanized steel and mounted upon a galvanized steel tower 60 feet high. In an extremely light breeze it was pumping 200 gallons of water per hour to a height of 30 feet, and as this was too great a quantity for the requirements of the bungalow the length of the stroke of the pump has been reduced by one-half. In Colombo we have an average diurnal movement of air varying from 150 to nearly 300 miles according to the season of the year. This means from 10 to 20 hours' full work. The mills are so regulated that they go out of the wind when it exceeds 15 miles per hour and no danger therefore exists of their being blown over. The towers being of steel, galvanized after being made, are practically indestructible, and their gracefulness and airiness greatly beautify the landscape. This is the first, as we have said, to be erected in Colombo; but Messrs. Davies have another of the same make in Chilaw, presently being erected for the purpose of pumping water from a river on to some arid lands, and thus converting them into paddy fields. The Devon House one supplies water for domestic and bathing purposes in the house, as also to the stable and coach-house, duck-pond, fountain, and for sprinkling the lawn. In America there are small town water supplies consisting of windmills mounted on large tanks and capable of pumping and storing the water for 800 to 1,000 inhabitants. This would be of great benefit in many towns in Ceylon:—Negombo, for instance. In America also these "Aermotors" are erected at most railway stations.

ARTIFICIAL MANURES.

Brazil.—With a view to preventing the numerous falsifications noted of late in chemical manures, imported from abroad or prepared in Brazil, the Farmers' Association of the State of St. Paul have just petitioned the Congress of this State to pass a law for stopping the sale of these fraudulent makes.—*Belgian Consul at Saint Paul.*

"Now Thunder and turf!"

Pope Gregory said
And his hair raised his triple
crown right off his head—
"Now Thunder and turf! and
out and alas!

A horrible thing has come to
pass!

What!—cut off the head of a
reverend Prior.

And say he was *only* (!!!) a
bare-footed Friar!

'What Baron or Squire,
Or Knight of the shire
Is half so good as a holy
Friar?

O turpissime!
Vir nequissime!

Sceleratissime!—quissime!—
issime!

Never, I trow, have the *Servi*
servorum

Had before 'em
Such a breach of deco-
rum,

Such a gross violation of
morum bonorum,

And won't have again *secula*
seculorum!—

Come hither to me,
My Cardinals three,
My Bishops in *partibus*,
Masters in *Artibus*
Hither to me, A. B. and
D. D.

How a Planter Terrifies a Crimp!

Doctors and Proctors of every degree!
Go fetch me a book!—go fetch me a bell
As big as a dustman's!—and a candle as well—
I'll send him—*where* good manners won't let
me tell!

TEA IN AMERICA.

NEW YORK, April 7th.

Elsewhere we print from a copy of the official report the recommendations of the Board of Experts to the Secretary of the Treasury, regarding tea standards to foreign importations. They practically exclude two-thirds of the Pingsuey teas and many low grade Oologs. A protest has been filed with Secretary Gage by Mourilyan, Heimann & Co., of Japan, through their local office as follows:—

Dear Sir,—In the matter of the recent act "to prevent the importation of impure and unwholesome teas," we beg to protest against the adoption by the Department of the standards recently selected for Japan teas, for the following reasons:

First.—That all Japan teas, being prepared from one and the same leaf, it is not necessary to establish more than one standard.

Second.—That the three standards, as selected by the Commissioners, represent three different qualities of this one leaf, the sundried tea being better in cup quality than the pan-fired tea, the basket-fired tea still better than the sundried. The effect of this confusion will be detrimental to the Western trade, where sundried teas are used and will favor New York, where the trade is almost entirely pan-fired tea.

Third.—That the standard of pan-fired tea as selected, is apparently early second crop tea mixed with first crop leaf, the result being that in a number of successive drawings the cup quality varies from 1 to 3 cents per pound.

Fourth.—As in the preparation of Japan teas the same tea is frequently subjected to both the pan-fired and the basket-fired process it will be manifestly impossible for the examiner to determine by which standard such tea should be tested.

We have for many years been importers of Japan teas, and under the old law never had a tea rejected at any port in the United States; consequently, we have no interest in the "importation of impure and unwholesome tea," and we only ask that one fair and proper standard be selected in accordance with the spirit and letter of the law.

The present standards, although selected, no doubt, with care on the part of the Commission, are calculated to seriously disorganize the trade in Japan tea, and will greatly curtail the amount of business that could legitimately be done under a proper standard. The market is steady on low-priced teas, particularly Pingsuey. Several lines have been sold the past week, but the aggregate of transactions has been light. The distributive demand is slow.—*American Grocer.*

BRITISH NORTH BORNEO: TRADE RETURN 1895-6.

The total Exports amount to \$2,420,234'39 against \$1,962,350'19 for 1895 or an increase of \$457,884'20. Out of 38 headings 28 show an increase. Tobacco showing the largest, and accounting for one-third of the total increase on exports for the year, 8,700 bales were shipped in 1895, \$10,448 in 1896, and it is estimated that the 1896 crop shipped in 1897 will amount to 14,500 bales.

Rattans, cutch, timber, guttah, coffee, dried fish, copra, live stock and gambier come next; and the increase of export in each of the above over 1895, is,

Tobacco	.. \$311,008 or about	.. 32 per cent
Coffee	.. " 11,295 "	.. 73 "
Gambier	.. " 2,609 "	.. 270 "
Copra	.. " 3,408 "	.. 54 "
Cutch	.. " 28,668 "	.. 25 "
Timbor	.. " 20,620 "	.. 26 "
Dried fish	.. " 9,694 "	.. 136 "
Rattan	.. " 83,852 "	.. 87 "
Guttah	.. " 11,456 "	.. 27 "

The exports have fallen of principally in camphor, damar, sago and sundries, but the decrease in damar is partly accounted for by a decrease of the import from outlying islands more especially Palawan. The Gross volume of trade has risen from \$3,626,256'83 in 1895 to \$4,302,423'03 in 1896 or a gross increase of \$676,166'20 which is rather more than 18 per cent.—*British North Borneo Herald*, April 16.

MOLLENDO RUBBER IN LIVERPOOL.

The grade of crude rubber indicated here derives its name from the port of Mollendo, on the Peruvian coast, whence it is brought by rail from Lake Titicaca, its original source being the section of Bolivia which lies above navigable portions of the river Beni and the streams running parallel to it. It is only a year or two since Mollendo rubber began to make its appearance in the Liverpool market, yet in their latest annual review Messrs. Kramisch & Co. say:—"An important feature during 1896 was the increase in the imports of Mollendo sheets and biscuits. The inquiry was only moderate during the first few months, in keeping with the supply, which was then only small. It was during the latter half of the year that the imports increased considerably. The lots brought to market were quickly bought up, so that the increase in the supply did not depress the value of this rubber; on the contrary, the margin between Mollendo and the ordinary soft-brown-cure fine decreased; and we see as much as 3s 5½d paid for Mollendo fine in July, at a time when the same price was quoted for soft-brown-cure fine, and 3s 4½d to 3s 5½d in November, when the value of soft-brown-cure was barely ½d more. About 1,500 bales have changed hands during the past six months, 3s 2½d being the lowest and 3s 5½d the highest prices realized." A recent report by the British consul at La Paz, Mr. Alfred St. John, states that rubber trees are abundant throughout the Bolivian forests, but every port of the republic is difficult of access. La Paz is reached by four days travel from Mollendo, by rail and lake steamer, after which twenty-two more are required to reach the Beni rubber region. The amount of rubber exported via Mollendo in 1894 is stated at 85,000 pounds.—*India Rubber World*, April 10.

NATAL BARROWGREEN TEA.

It will be remembered that, about three months ago, a successful Ceylon tea-grower (Mr. John Fraser) visited Natal, and inspected all our tea estates. He readily recognised that Natal was favourably situated for the growth of tea, and suggested points for improvement in manufacture. He little thought at the time that he would himself be connected with the industry in this Colony, but, just before he left, after arranging to send a practical man from Ceylon, he was prevailed upon to promise to return himself and take over the management of the Barrow Green Estate. He returned from Ceylon a few weeks ago, and at once set to work in putting that estate in order, and manufacturing a tea that he felt would recommend itself. Desirous of proving the quality of the tea by the first public test, he determined to exhibit at the Johannesburg Agricultural Show, and he did this with tea that was only picked at the beginning of March, a fortnight or so before the date of the show. Despite the "newness" of the tea, he has had the satisfaction of returning from the show with three first prizes and also a gold medal for the best exhibit of tea, and the samples he took were readily purchased at good prices. If so much can be accomplished in so short a time, it is evident the experience and knowledge of men like Mr. Fraser should have valuable effect on the tea industry of this Colony. Calling upon us the other day, he pointedly asked how it was that Natal, with two years' start of Ceylon, had not yet turned out a million pounds' weight of tea per annum, while last year Ceylon's output was 100,000,000 lb. and this year it would be 115,000,000 lb. Answers to that question might elicit useful information. Mr. Fraser brought us samples of the prize-winning teas, which we put to practical test by trial on the domestic table. With the exception of the "newness" referred to, and which, of course, was to be expected, the teas were exceedingly good. The Pekoe Souchong is the one of common demand, and properly aged (as Mr. Fraser says all the Company's teas will be before being permitted

to leave the estate), it is sure to be in much favour. The Orange Pekoe and Golden Pekoe are, of course, higher grade teas, and they are decidedly real good teas to drink. Of nice colour, there is body and flavour in them without harshness. While Natal tea as a whole has undoubtedly improved, there is still room for progress, and the time is not far distant when the yield and sale should be considerably increased. Competition will certainly do good.—*Natal Mercury*, April 9.

CATTLE PLAGUE (RINDERPEST).

Rinderpest, commonly referred to as "mur-rain" (a term which is unfortunately sometimes confused with foot-and-mouth disease) has been one of the chief subjects with which agricultural and veterinary papers have been occupied, since it began to be the cause of so much devastation in South Africa, where the loss of cattle by this epizootic has been something appalling. Here, in Ceylon, cattle plague may be said—like the poor—to be always with us, and it is a question whether the aggregate of our annual losses from this plague (say for 25 years) does not exceed the loss caused by a visitation such as has occurred at the Cape. It is well-known that the Government of Cape Colony engaged the services of Dr. Koch, the eminent Berlin scientist, to investigate the cause of rinderpest and, if possible, discover a means of cure, and later on we were informed by telegram from Reuter that Dr. Koch—who is now in India—had discovered a preventative against the plague.

Hitherto, the only effectual method of dealing with rinderpest has been by slaughtering both the infected animals and those which have been in contact with them, combining with this the strictest quarantine regulations. In this way rinderpest was once and for all stamped out of Britain, and in those districts in which the same treatment was adopted at the Cape, the losses were considerably less. For instance, in the district of Mafeking where cattle were not shot down, there were no less than 80,000 deaths from the plague, while in Barkly West, where 12,000 diseased animals and animals in contact with them had been shot and the disease so prevented from spreading, only 600 died of plague, making a total loss of 12,600 head of stock. It is not every country, however, that can adopt such drastic but effectual measures; but where they can be enforced, as in India, very energetic action in enforcing quarantine rules is necessary to localize and check the spread of cattle plague. It has been truly said that to attempt anything like medical treatment is only "playing with fire."

The local *Agricultural Magazine* included in our monthly T. A.—has been reprinting the interesting reports made by Dr. Koch on his investigations at the Cape, and those who have read these reports will have some idea of the delicate nature of the work which the great scientist has had to face. The details certainly afford most interesting reading. We would, therefore, wish to refer, not to the various trials which had to be carried out before the successful attempts to prevent liability to the infection of rinderpest were arrived at, but to the successful results themselves. The following extracts from Dr. Koch's fourth and most important Report will speak for themselves:—

"In my last report I was already in a position to inform you that blood-serum of cattle which have recovered from Rinderpest had a certain immunising

effect upon healthy stock when inoculated with it. Its protective properties however are not very great, for 100 ccm. of such serum are required to protect an animal against an inoculation with a small dose of Rinderpest-blood. This immunity is in its nature merely a "passive" one and will only last during a short period. For protective inoculation on a large scale such serum is not applicable, but I succeeded in immunising within a fortnight several animals by means of a mixture of serum and virulent Rinderpest-blood to such a degree that they were enabled to withstand an injection of 20 ccm. Rinderpest-blood, a ten thousandth part of which is a fatal dose. From this fact I judge that the immunity of these animals is of a much higher degree and I believe it is an active immunity, equal to that of a beast which has contracted Rinderpest and recovered. It is particularly important to know that only 20 ccm. of such serum are required to immunise one animal, and therefore one litre (nearly 1½ imperial pint) suffices for fifty head of cattle. My further investigations concerning this *modus operandi* will aim at finding

If this immunity is obtainable in a still shorter period;

If a still smaller dose of serum will suffice and if it may be attained with but one injection.

"A second and equally important fact is that one is able to render immune healthy cattle with the bile of such that have succumbed to Rinderpest. In this case only one hypodermatic injection of 10 ccm. is sufficient. This immunity sets in on the 10th day at latest and is of such an extent that even four weeks afterwards 40 ccm. of Rinderpest-blood could be injected without any injurious result. I therefore conclude that the immunity produced in such manner is of an 'active' nature. The local result of an injection is merely a hard, somewhat painful swelling of the size of a man's fist and which gradually disappears in the course of a few weeks, provided, however, that the bile is not in a state of decomposition as is not uncommon when an animal suffers from Rinderpest. Under such circumstances an abscess may form, which, however, does not seem to be detrimental to the process of immunisation.

"Both these above-mentioned facts convince me that Rinderpest can be eradicated with but little difficulty, and within a comparatively short time, by putting these methods into practice. The method of immunising cattle with serum may be used in order to separate from infected areas those tracts of country which are still free from the scourge by means of forming a broad belt between them in which all the cattle are inoculated with the vaccine. The protective properties of the bile will be of inestimable service in infected parts. Nearly every case of Rinderpest supplies a greater or lesser quantity of vaccine for those animals which are still healthy. I cannot but urge upon you the importance of bringing this method immediately to the notice of those cattle-owners whose animals are suffering from, or threatened with, the disease, as I am sure thousands of cattle may daily be saved by its application."

"The *modus operandi*," adds Dr. Koch, "is very simple in both these methods." We hope to hear before long that the Government Veterinary Surgeon has begun acting upon the results of Dr. Koch's important work in a systematic manner. So far we are not aware that any systematic veterinary investigations have been carried out in the island. The life of a Veterinary Officer in an island like Ceylon, if he is to prove really useful, must needs be a very active one, as active if not more so, than that of a medical inspector. We learn that in the Cape the services of the Government Veterinary Surgeon are available to anybody in the Colony, and that that officer must attend upon, or give advice regarding any case reported to him free of charge.

This is as it should be, provided that the officer is well remunerated by Government and that all cost of travelling is also refunded.

There is no gainsaying the fact that the prevalence of cattle plague in the country divisions (reports of which are given month after month in the season reports published in the *Gazette*) accounts for a good deal of the failure which frequently attends cultivation in our villages. We trust, therefore, that Government will see fit to direct the Colonial Veterinary Surgeon to carry on his work in connection with the suppression of Cattle Plague, on the lines indicated by Dr. Koch, and to make a report on the results of that work.

PLANTING IN BRITISH CENTRAL AFRICA.

The first foal born and reared in British Central Africa is now being broken in at Zomba for riding. It is a very tractable little animal and promises to turn out useful. It is a stallion, and we will hope may be the sire of a future Shire Highland breed.

During the last few weeks plantations in the Zomba District have been simply flooded with Anguru, Anyasa, and Mangoche men. This is a new departure at this time of the year, we understand, and no doubt those planters who benefit by it will welcome it.

Nkanyela, a chief on the shores of Lake Chilwa, has of late been sending in messages to Zomba and assurances of his desire to be great friends with the Europeans. His assurances have also been accompanied by a fair number of workers, Anguru. From the Namaramba country, north of Lake Chiuta also labourers are beginning to come in.

The African Trans-Continental Telegraph Company have very liberally offered, if the Collector at Chiromo will from time to time wire to Blantyre the movements of steamers, mails, &c., on the lower river, to send out notices to the different offices at Blantyre and Zomba. This no doubt will be a great boon to all Blantyre and Zomba residents.

The Telegraph Company are making excellent progress with the construction of their line towards the north. The wire has now reached the Upper Shire and will before long be at Fort Johnston; and Major Forbes hopes that the present year, the "Soixantaine," will before its close see the north of Lake Nyassa in telegraphic communication with London.

On the Mlungusi Estate of Messrs. Buchanan Bros. a number of orange trees are now in full bearing.

Out in the Mlanje-Zomba plains, on the Ntondwe river, there were recently found a number of lemon trees bearing heavily. As they are near to the site of the original "Magomero" Mission station it is supposed that the trees must have been planted by the first missionaries established in B. C. A. The fruit though very large and of good flavour, has an unusually thick skin.—*B. C. Africa Gazette*, April 1.

POLISHING A PAIR OF HORNS.

Remove all the rough outer part with a rasp, followed by a file. Then well scrape with a knife, steel scraper, or side of a steel chisel to remove all file marks. Then standpaper off with various sizes of sandpaper, finishing off with the finest. Now carefully dust to remove any particles of sand, and repeat this dusting between every two of the subsequent operations. To polish the horns, apply, by means of a rag dipped in linseed oil, some of the horn-dust saved during the previous processes, and rub smartly. Next apply some putty-powder or rottenstone by means of a flannel damped in water, and again use plenty of rubbing. Whiting is next employed by the aid of a rag damped in vinegar. Follow this with a chamouis leather and a little oil, then with a clean dry leather, and finish off with a sharp rubbing with the bare palm. Or a lathe and various "bobs" can be used in polishing.—From "*Work*" for April.

“QUININE AND CINCHONA BARK.”

We have been greatly interested in a very full and carefully prepared historical and commercial *resumé* recently published under the above heading by the New York *Oil and Drug Reporter*. It begins with 1871, the year when the journal was first issued, and it deals freely with the American quinine manufactories, at Philadelphia and elsewhere, all of which we personally visited in 1884. In 1871, quinine was about 11 shillings an ounce, protected in the States by a duty of 45 per cent; reduced in August 1872 to 20 per cent. “Chills and yellow fever raged in the summer of 1872,” we are told and the consumption of the alkaloid was large. It was even proposed to grow Cinchona bark in the South Western States of the Union; but Ceylon and India, with their cheap supplies, soon settled that. In 1877, however, the cost of quinine advanced to 18 shillings an ounce—but only very temporarily. Early in 1879, the price began to go down and the tax on imported quinine was abolished. The New York *Sun* then published the following poem on the “emancipation” (?) of that portion of the human race domiciled in the United States:

Rejoicings ring throughout the land.
Quinine is free! Quinine is free!
Its bonds are burst, its shackles fall.
Send the glad news to one and all,
Through shanty, tenement and hall—
Quinine is free! Quinine is free!

Malaria flies in wild alarm.
Quinine is free! Quinine is free!
And fever hides her burning head,
And ague totters off in dread—
Economy quinine had wed!
Quinine is free! Quinine is free!

* * * * *

Now all one saves in Jersey rents—
Quinine is free! Quinine is free!
In dollars, dimes, in cents and mills,
Won't go to pay the doctors' bills,
Or druggists' for Peruvian pills.
Quinine is free! Quinine is free!

Hope dawns again upon our land.
Quinine is free! Quinine is free!
All joyful shout from near and far,
“Hail, quinine, sugar-coated star.”
And ague trills “Hurrah! Hur-r-r-rah!”
Quinine is free! Quinine is free!

Some of the minor alkaloids came into use after this and still further affected the price of quinine pills of which, however, were getting into universal use throughout the States. The demand in 1881 increased by 25 per cent, and American manufacturers turned out 1 million ounces—other makers' returns being as follows:—

	Ounces.
Howard	350,000
Whiffen	122,000
Jobst	315,000
B. & S. Mannheim	315,000
Brunswick	210,000
Zimmer	210,000
F. Koch Oppenheim	52,000
Pelletin	140,000
Trillardieo	140,000
Schissmann	55,000
Dufour Fratilli (Genoa)	105,000
Lombard, Milan	1,400,000

The capital stock of the last-named concern was \$800,000.

Here is one interesting bit:—

Early in the year 1884 Stallman & Fulton became agents for Zimmer's brand, which was put out in an entirely new dress. On Feb. 28 occurred the fire in Powers & Weightman's factory, which started in the bark grinding department. The damage amounted to \$300,000, and affected the quinine factory, the bark mill and the opium and morphine warehouses. Mr. Alexander Boehringer had just arrived from Europe, and been taken off on a tug in the lower bay, by his friends, so that his presence here might not be generally known. He went direct to Philadelphia and offered the use of the Milan factory to Powers & Weightman, pending the rebuilding of the works. His offer was accepted, and in March Dr. John F. Weightman sailed for Europe to perfect arrangements for placing goods on the market as soon as possible. In the summer the Milan factory failed, with liabilities of 18,086,043 francs, and assets of 12,617,489 francs. The capital of 6,000,000 francs had disappeared.

Our proposal at this time in the *Ceylon Observer* to introduce quinine into China as a substitute for opium, and also to use it for horses and cattle, is specially noted by the reviewer. A little later, the price was down to 2s 3d the ounce and the yield from the Ceylon barks alone was five times the consumption. In 1887, we read:—

Toward the end of the year people began to talk of a combination. Kcasby & Mattison issued a circular, in which they stated that quinine could, and would, be sold at 25c. (1s 1½d) at a profit, and that Java barks would make this possible.

Passing on to 1892:—

Apparently the Java planters did not tire trying to improve their position, as they formed a syndicate early in 1892, to which 500,000 florins was contributed which was to be used to bolster up the bark market at the auctions. They succeeded in bidding up the price, but it appears that the higher bark went the lower quinine went, as there seemed to be no prospect of a combination of the manufacturers being formed. Furthermore, the Baring failure had compelled the throwing on the market of a large lot, which had a depressing effect.

Finally, of 1896, we read:—

The year just closed witnessed a complete collapse of the market, in spite of which the agreement between the manufacturers remained unbroken. While Ceylon had become of little or no account as a producer of bark, the exports from Java had increased enormously, and manufacturers found that they could not take all that was offered. They therefore allowed the market to take its course, with the result that the lowest price on record was reached during the year. European competition was threatened, and with a promise of the early operation of the Java factory, they determined to reduce the price of the alkaloid as a measure of self-protection. As indicating the view of the situation which was held by dealers, large sales were made at 25 cents in July from second hands. The first official drop was announced Aug. 17. It amounted to 3 cents, which brought the price down to 25@27 cents, according to brand. A week later there was a further drop of 3 cents, and on Nov. 2 the price was still further reduced, this time 4 cents, making it 18@20 cents. Second-hand holders were completely demoralized at each successive drop, but they followed the market in its downward course. There are several holders of quinine who purchased large quantities of it on speculation at prices ranging from \$1.50 down to about 30 cents, and many of them still hold their stocks, in the hope that some day or other conditions will improve to such an extent that they may be able to dispose of them, if not at a profit, at a smaller loss than they would be compelled to submit to if they sold at the price at the close of the year.

MEXICAN INDIA-RUBBER.

The popularity of the cycle and the introduction of electric motor cars has caused such a "run" upon India-rubber that those engaged in the manufacture of tyres have begun to realize the great risk there is of supplies becoming exhausted. The formation of the India-Rubber (Mexico) Coy. Ltd., will therefore be hailed with satisfaction, by the "trade," and we should fancy that the promoters will have no difficulty in disposing of all the available shares. The Company has been formed to acquire plantations in Mexico (known as "La Esmeralda" and "Llano de Juarez") of over 440 square miles of freehold land with 350,000 India-rubber trees already available for tapping. The estates also carry a great deal of valuable timber, and certain portions of them appear to be adaptable to the purpose of growing cacao trees and coffee plants. There are also large plantations of chick gum trees, which produce the chewing gum so popular in America. The share capital is £406,000, divided into 400,000 ordinary shares of £1, and 6,000 deferred shares of £1 each. The latter will not be entitled to participate in the profits of any year until fifteen per cent. for that year has been paid on the ordinary shares, when they will be entitled to one half of the remaining profits distributed as dividend. There is also an issue of £200,000 seven per cent. first mortgage debentures of £50 each, redeemable after five years by annual drawings at £60 each, at the option of the directors. A working capital of £50,000 is provided for, and the vendors take £556,000 for the properties, payable as to £150,000 in cash, and as to the balance in cash or shares, or partly in both, at the option of the directors.

Turning to the details given in the prospectus we find it stated:—

The consumption of india-rubber by six countries now exceeds 100,000,000 lb. per annum, worth about £10,000,000, and during the last few years the demand for it has increased enormously, and is still increasing; whilst hitherto practically no steps have been taken to meet this growing demand, or to provide for the world's future requirements. Up to the present time nearly all india-rubber has been obtained from wild trees, but it is admitted by those most competent to give an opinion that such a source is barely adequate to meet the present demand, and that the supply of the future will have to come largely from trees properly planted and cultivated. This view is corroborated by the following extract from a recent report to the Foreign Office:—"Judicious 'tapping,' with due regard to the life of the tree and its future usefulness, is the exception; rubber-bearing trees are ruthlessly sacrificed by irresponsible seekers after wealth, and dead trunks are becoming a too familiar feature in the landscape of the productive districts. Sooner or later a purely destructive policy or this kind must exhaust the richest country."

SUBSIDY TO PLANT RUBBER TREES.—A subsidy has been granted to the owners of the "Llano de Juarez" by the Mexican Government, providing for a Treasury payment of 3 cents for every india-rubber tree planted which attains a certain growth up to a limit of 15,000,000 trees; equal to about £3,000 per million trees, the trees to be planted at the rate of 1,050,000 per annum. The first year's yield in 1905 from the million trees to be planted this year should be £250,000 rising in 1908 to £500,000. The first year's yield in 1906 of the million trees to be planted next year should be £250,000 rising in 1909 to £500,000, and so on. Under the concession granting the subsidy, the Government has the right of pre-emption at the end of 99 years of the lands planted (with the buildings and utensils) at a valua-

tion less an amount equal to double the amount paid by way of subsidy under the concession.

If from any unforeseen causes the estimates of revenue contained in the prospectus, and upon which the directors are proceeding, should not be realised in their entirety, there is an ample margin shown in the estimates to provide for every contingency, after payment of handsome and yearly increasing dividends.

DEMAND.—India-rubber has become absolutely indispensable to the cycle tyre, electrical motor cars, cab, and innumerable other manufacturing industries. It is a matter of common knowledge that the consumption of india-rubber in the manufacture of cycle tyres alone has grown by leaps and bounds. In 1886 there were 68 cycle factories in England—there are now more than ten times that number. In France, America, Germany, Australia, and other countries there has also been a large development of the cycle trade. In 1896 no less than 262 undertakings dealing with the cycle and motor industries were registered in London alone, with a total capital of £19,898,464. The increasing demand for India-rubber has caused manufacturers to awake to the problem of a threatened exhaustion of supplies; it is, therefore, beyond question that this Company will supply a want distinctly felt by all manufacturers using india rubber and that it has every reasonable prospect of richly rewarding its shareholders.

TREATMENT OF RUBBER.—It is intended that the rubber shall be collected and treated under the care of a resident rubber expert on the most approved scientific principles, so as to command the highest market price quoted for the best samples of raw rubber. Such rubber on the market is worth about 3s 6d per lb, and its superiority over other rubbers is due to the scientific methods employed in its collection ensuring freedom from dirt and impurities. It is anticipated that by the adoption of similar means in gathering the product of this Company's estates it will, instead of realising 1s 8d per lb net, find a ready sale at 2s 6d per lb net. Hitherto there has been but a comparatively small output of india-rubber from Mexico, collected in a most primitive fashion, and although in addition to the Company's plantations wild rubber trees grow in great numbers upon their lands, no organised efforts have been made to exploit the industry. No comparison, therefore, can be justified between the raw rubber which this Company proposes to put upon the market, and that of any other rubber which has ever come out of Mexico.

TEA AND COFFEE IN CEYLON.—A colonist of the "forty-fifties" writing from London by a recent mail, gives some advice to planters:—

Tea Company forming, I notice, still goes on and large prices continue to be given for estates. I met Mr. Tom Gray just before his last visit to your side, and was glad to find his great confidence in the tea enterprise. There will be ups and downs as in all enterprises. There will be those who have paid too much for their whistle; many who have cultivated without proper regard for economy; and wiser men who worked cautiously, careful of expenditure, avoiding as much as possible loading their properties with debts for advances from capitalists. The same varying fortune will characterise the tea as formerly the coffee enterprise.

When I arrived at Colombo in 1841 in Messrs. Tindall's ship "Achilles," there was another ship, the "Euphrates," also owned by Mr. Tindall, destined for China, with one more vessel, a charter for oil by Wilson & Co., afterwards Wilson, Ritchie & Co.; 3 ships in all! How many now? The reply will show the advance Ceylon has made.

In the present day, our harbour has often, 18 or more large ocean-going steamers at once within its bounds at anchorage.

ROSES IN CEYLON.

(By a Practical Horticulturist.)

May 10th.

Of all plants grown in Ceylon for their flowers none gain so much the admiration of lovers of flowers (and who are not?) as the Rose. It is not therefore surprising that queries regarding it are so frequent and varied; and "Lady Horticulturist" in your issue of the 26th ult., renews the subject. There is probably no household in the island possessing any piece of a garden, large or small, who does not find a corner therein for *Rosa*; yet it is but comparatively few years ago that the introduction of this favorite into Ceylon would have been considered as unlikely as that of the Scotch heather would be nowadays. Temple offerings of flowers of the jasmine and the temple-tree, which with true followers of Buddha have always been considered indispensable at temple ceremonies, seem now to be giving way to the more delicate charms of *Rosa mal* (rose flowers). When paying afternoon visits, incorporated in the conversation about tea, labour, and cacao disease, must assuredly be "Our Roses."

The Thistle it must be admitted has charms all its own, the old Shamrock recalls the hearts of the truest patriots; and the gallant little Leek is doubtless useful in its own sphere, finding as it does particular favour under the name of *Lumi* with curry-stuff connoisseurs in Ceylon; but the Rose has floral beauty that is at once striking and superlative, and is justly designated the queen of flowers. It is the national emblem of England; it is the favourite flower of Queen Victoria and also, I believe, of her representative in Ceylon, Her Excellency, Lady Ridgeway. It stands as the head (or type) of a family unsurpassed for beautiful and fragrant flowers and luscious fruits; e.g., the peach, pear, apple, strawberry, not forgetting our familiar loquat.

Probably no other genus of plants has received so much attention from authors and poets of all countries as has *Rosa*. To Aurora, it was dedicated as the emblem of youth; to Venus, of love and beauty; to Cupid, of fugacity and danger. The latter, according to classical writers, gave it as a bribe to Harpocrates, the God of Silence, hence the saying, "under the rose."

The rose is almost as cosmopolitan as a Scotchman. Left to itself it finds a congenial home as far north as the sub-alpine zone, and by cultivation it flourishes in equatorial regions. Apart from its floral attractions, it forms an important factor in commerce, the manufacture of rose-water and attar alone giving employment to perhaps millions of persons. This is an industry which should be peculiarly adapted to the Sinhalese villager, and as roses may well be grown on a large scale up-country, who can say but the precious and expensive attar may in the no distant future, figure prominently in our sources of revenue.

Rosa contributes largely to our *Materia Medica*. "Dr. Lindley, one of the most earnest defenders of its powers, has not hesitated to assure the world that the Pharmacoposia should be formed of roses alone."

It has been well said that a garden without roses is a misnomer. The fine display of these at the recent Nuwara Eliya Show was in itself proof of the success that can attend their careful cultivation in the island. Roses are not so difficult to manage as is generally supposed, the chief difficulty, in the low country, really consists in suitable soil not being available in large enough quantities. In selecting a site for a rose-bed, or beds, it is a mistake to choose a shady place, as some people do with a view to sheltering the plants from the sun and heavy rains. An open airy situation is best; trespass of roots from surrounding trees which impoverish the soil and rob the plants of the manure intended for them is to be guarded against; it being often necessary to cut open a deep drain to check their transgression. Roses delight in a loamy and somewhat tenacious soil,

which should be enriched by occasional applications of farm-yard manure. As to pruning, they yield best to this operation at the beginning of the monsoons. It is a great mistake, as many find from experience, to prune severely if any, in the hot and dry months which is practically winter here (paradoxical though it sounds), because growth is then more or less inactive. At this time they will also greatly benefit by having the earth about them covered with dead leaves or litter to prevent excessive evaporation of moisture from the soil and check the penetration of the fierce sun's rays to the roots.

PROPAGATION.—It is comparatively easy to propagate roses by means of "cuttings." There are two distinct ways of performing this operation: the right and the wrong way; the latter being generally followed by our garden wallah if left to himself. Send him to plant a bed of rose cuttings, and ten chances to one he will proceed something after this fashion. He will carefully stir the soil with his mamotte, and will then assume the sitting posture peculiar to his class, i.e., by resting the posteriors on the heels with wonderful agility and perfect ease; after taking considerable pains to make a smooth surface by means of a splinter of bamboo he will proceed to insert the cuttings (merely sticking them in the soil) packing them together in the line as closely as possible, and taking particular care to have all the upper ends on a uniform level, but paying little or no heed to the position of the cutting in the ground. Most probably not more than one per cent of these will grow, and as decay sets in, white-ants begin to make food of them; consequently *Termites fatalis* is severely railed at for having "destroyed the rose-cuttings," which, as a matter of fact, are dead before they are thus attacked.

It need hardly be said that if we wish for better results a different method must be adopted, and Ramasamy will have to be taught by practical demonstration that a roseplant requires to be differently treated from a tea-bush. Get him, if you have not the time or inclination yourself, to dig the bed quite a foot deep, at the same time mixing in some manure and a quantity of leaf-mould, if available; rake over the surface, not too finely, but evenly; open across a shallow trench about 6 inches deep; place the cuttings sloping-wise against the steeper side at least 4 to 5 inches apart, about which sprinkle some sand (river-sand preferably) and fill in with the soil, pressing it moderately firm around the planted cuttings; open the next line about 7 inches distant, and proceed in the same way. In preparing the cuttings all the buds should be carefully preserved, and it is not by any means necessary to strip off all the leaves which are to be above ground; these had better be left to wither away of their own accord, for as long as any green is left they will supply some nutriment to the cutting, and when withered will afford shading to some extent. It is of course essential after planting that the cuttings be kept shaded (cadjan leaves being most convenient for this purpose) and the ground moist until they show signs of making young growth.

VERMIN.—In this country no enemy of the Rose has a worse reputation than the white-ant; yet, as is already pointed out, on careful examination I have no doubt it will be found that all healthy plants are altogether secure from its attacks, its ravages being confined to diseased or decayed vegetable matter; so that it may really be regarded as a useful scavenger. However, the presence of white ants in a garden is by no means to be desired. The most reliable means of diminishing their numbers is by digging up their nests or haunts and destroying the queen-ants. Roses that are infested with thrip, black-fly, and such like, should have frequent syringings, morning and evening. If that is not effectual, dilute a wine-glassfull of kerosine oil to a gallon of hot water, and apply quite hot by a syringe. But roses are said to be as yet more free of insect pests and parasites in Ceylon than in any other country in which they are cultivated, and that they may long continue to be so will be the wish of all of us.

ANNUAL RINGS IN THE NIM TREE.

In Gamble's Manual of Timbers it is remarked that it is not known whether the rings in the wood of the Nim tree (*Melia indica*) are annual or spurious. There is a forest plantation of Nim at this place (Tunmuru Kodu) in which Nim trees were planted 14 years ago. I had some of them felled lately, and examined the rings. I found that the 14 annual rings were clearly marked, but that in addition there were other spurious rings which however did not go round, but merged into the annual rings. In fact the spurious rings seldom went more than a quarter way round. If the rings of the Nim are counted care will have to be taken about these spurious rings.
A. W. LUSHINGTON.—*Indian Forester.*

THE PALMYRA PALM.

How very closely palmyra leaves can sometimes pack themselves on the stem. Of course the majority of the leaves die off, only about 6 or 8 remaining alive at a time. The diagram is supposed to represent the unrolled circumference of the tree, and in a height of 3 inches from base of petiole to base of petiole 17 leaves were crowded together. The young leaf petiole, when green, is sheathing, but when the leaf dies and the stem distends, the sheath splits, making the base of the petiole appear forked. A scar is left behind on the stem the whole horizontal length where the leaf has at any time adhered. The leaf scars form almost continuous spirals round the tree, and I fancy that by their means a rough approximation of the age of the tree can be made. Here the trees yield on the average 10 leaves per annum; 17 leaves gave 11 rungs of the spiral ladder, so that there would be 6 such rungs per annum. This requires further elaboration, but I thought perhaps this might be of interest to you. Since writing the above I have had the opportunity of examining a great number of palmyras, and find that almost invariably the leaves come off the stem in whorls of 3, the bases of their petioles either touching or slightly overlapping. This fact is rather interesting as an extension of the trimerous formation of the floral organs of most monocotyledons. Of course the three leaves of the whorl in palmyras are not synchronous, one develops after the other. Since writing I have also come across the following, in Luedley's Introduction to Botany:—"It is said that the number of external rings which indicate the fall of leaves from the trunk of the Palm Tribe coincides with the number of years that the individual has lived. There is, however, no proof of this at present; such statements 'must therefore be received with caution.' If, as is said, from 10 to 12 leaves form in each year (I am now making experiments to test the accuracy of this), then, as three leaves go to form one of the external rings above referred to, from three to four of these external rings coincide with a year's growth, and not one only.

CEYLON TEA PLANTATIONS COMPANY.

(Special Report for "*Tropical Agriculturist.*")

The annual ordinary meeting of shareholders was held at the offices of the Company, 20 Eastcheap, London, on Thursday, April 29th, the Chairman, Mr. H.K. Rutherford presiding.

The CHAIRMAN, after saying that, though the accommodation was smaller in the new offices than they had been used to, there seemed to be ample room for all the shareholders who cared to attend, and remarking that if the smallness of the number of shareholders attending the meetings was a gauge of the prosperity of the Company the Directors would never want to see more gentlemen present than were there that day—(laugh and hear, hear)—said:—In submitting

the Report and accounts for your consideration (which I presume you will as usual take as read) it has been my pleasant duty on previous occasions to congratulate you not only on the favourable results of each year's working, but also on the sound financial position of the Company: and I venture to think on reference to the balance sheet now presented you will consider the traditions of the Company have been maintained. There is I think nothing in the figures of the balance sheet or profit and loss account requiring elucidation, but I would draw your attention to the fact that the capital cost of the tea properties with their buildings and machinery remains at practically the same total amount as last year notwithstanding we have added 265 acres to our tea acreage and also to our factory accommodation and tea machinery. Allowing for reserve fund and depreciation, the cost of the tea estates stands at about £22 per acre. The net profit for the year amounts to £48,986 10s 8d and we have placed £4,000 to depreciation, and added £15,000 to the reserve bringing this fund up to a total sum of £85,000 or £3,920 over the par value of the preference share capital. At the end of the year we had £34,469 of this reserve in good securities and £38,403 invested in coconut properties. The balance is at present being utilized in the general business of the Company, but will be invested as opportunity offers. We have planted up 572 acres with coconuts during the year and we are fortunate in having a most favourable season for putting out the young plants. The lands we have in bearing gave us a profit of £1,139 and we confidently look for a steadily increased return as with the better system of cultivation now adopted in comparison with the native treatment the trees should give a larger yield of nuts. We are now completing the erection of a fibre mill on the Mawatte Estate which we trust will be in working order next month. As the coconut lands come into bearing the profits accruing from our reserve will very materially increase and it is our belief that we have placed these funds in an investment which will not only prove profitable, but which also affords you as safe a security as can be found in agriculture, while at the same time having it under your own control. Turning now to the working of the tea properties, it is gratifying to find that there is no diminution of yield as the trees increase in age. The crop harvested was equal to 470 lb. of tea per acre over say 8,000 acres—a yield which is the highest average we have reached, but which, although an exceedingly fine out-turn over such a large area, will, I am sure, be eclipsed when the considerable acreage of comparatively young tea, especially on Glenlyon and Tangakelly estates are more mature. On the question of crop as far as we can see we have but little to fear. As to price, notwithstanding that Ceylon and India's crop last year exceeded all previous years by 17½ millions of pounds, the price of this Company's tea was not affected by this considerable excess as its average price was slightly better than that of 1895. Exchange, entirely beyond our control, affected us adversely as compared with 1895, diminishing our profits by about £5,000. Our teas cost somewhat more to produce last year which is accounted for by increased cost of firewood, in the plucking, owing to a prevalence of wet days, in expenditure on manuring, buildings and machinery and also the increased

cost of rice to our coolies owing to the Indian Famine. (Cheers.) The labor in Ceylon has lately become somewhat unsettled and this is attributed, I believe, in great measure not so much to a shortness of supply as to the action of certain new estate owners holding large interests in tea. (Hear, hear.) These proprietors or their representatives, either through ignorance or a total disregard of the system and customs hitherto in force as unwritten laws, have, by the heavy advances paid to secure coolies, while these coolies are employed on other estates, so unsettled the whole labor force of the island that it is to be hoped that some energetic steps will be taken by the planters of Ceylon to mitigate the evil, before it assumes greater proportions and thereby becomes even more serious than what it is at present. (Applause.) I am glad to say the labour force on the Company's estates is reported as being ample at the present time. To those shareholders who do not know the extent to which we are employers of labour it may be interesting to them to learn this Company employs 9,000 coolies and this army has to be provided by us with rice, their staple food, and when this commodity reaches famine prices, the loss does not fall on the labourers but on the employer. I may here incidentally state that the directors subscribed on the Company's behalf £50 to the Indian Famine Fund which I am sure will meet entirely with your approbation. I merely mention these various details affecting the cost of production as it might be thought by shareholders not conversant with tea planting that if we can produce a pound of tea at a certain low figure one year we should be able to do so every year. Fluctuations there will always be, but we can only hope that a high cost of production, together with a high rate of exchange and low prices will not come in conjunction (Hear, hear.) As you are aware our Company acts as agent for several smaller tea Companies and private proprietors, and, business resulting therefrom to a large extent provides for the London expenditure in working the C. T. P. Company. This branch of our business has increased so much that it has been necessary for us to move into the somewhat larger offices than those we formerly occupied, and to which we welcome you today. The interesting record of our ten years' work, which is shown in the statements attached to the report, is the best evidence we can give you, not only of our own work in your interest, but also of all those in our service in Ceylon, and you may rest assured that the same care and vigilance to secure the best results will be exercised in the future conduct of the affairs of the Company as has been in the past. (Hear, hear.) It is highly encouraging to our enterprise that the consumption of British grown tea is steadily increasing outside of Great Britain. (Hear, hear.) Indian and Ceylon teas in 1894 were taken by other countries to the extent of 27,000,000 lb. and in 1896 to 40,000,000 lb. or an increase of fifty per cent; and it is a further matter of congratulation for Ceylon growers to know that 70 per cent of this increase was contributed by Ceylon. America and Canada in 1894 took 4,700,000 lb. of British grown teas, and last year 9,500,000 lb. so that if the combined efforts of India and Ceylon are continued with persistency we may hope to see in a few years' time a very greatly increased volume of our teas being taken by these countries. Mr. Talbot, who has just returned from Ceylon, is here today, and is in

a position to tell you how your various properties were looking, as he visited all the estates in which we are interested. (Hear, hear.) We shall be very pleased to reply to any shareholder who wishes for information on the subject of the report and accounts which I may have omitted. The Chairman then moved the adoption of the report and the payment of a dividend of 8 per cent, making a total of 15 per cent for the year. (Applause.)

Mr. G. A. TALBOT seconded the motion. He said he had been all over the properties in Ceylon. The points to which one looked for the permanence of tea on the continuance of good bearing were chiefly, the way in which the bushes were plucked, and the way in which they were manured. The plucking, he had no hesitation in saying, was very carefully done in 1896. The bushes had not been hard plucked. As regarded exhaustion, only the minimum had been taken out of them, and if for any reason the Company wished to get more out of the bushes and decided to pluck them hard they could very greatly increase the yield. As to young tea, the policy they pursued before had been carried on—letting it come to full size before being plucked at all. Their fields were healthy. They had not done much artificial manuring. During the past two years they had done a good deal in the direction of natural manuring; they had planted grass and built cattle sheds, and the present manager and the superintendents under him were anxious to extend this system as far as possible. As to the coast advance question, which was a burning question for them, he would explain that the coolies came from Southern India and the planters gave coast advances to men to bring them over. When the coolies left the Ceylon estates they had only to pay for the debt incurred in bringing them from India. For some years the system worked well, as the amount of advance was not excessive. But some capitalists had lately come to Ceylon anxious to open large acreages for tea, and had offered large sums for coolies to go into their employ. £100 had been offered. This was more than the average Oriental could ever pay back, and the result was very demoralising. (Hear, hear.) He felt sure those interested in these Companies at home were not aware of the evils of this system, and that was why he spoke out so fully about it. It was obvious that if one advanced to any labourer more than he could ever pay back, it was demoralising because he knew all his wages would be taken to pay the debt, and he was therefore not anxious to do any labour at all. The people who had paid these big sums had recently written them off in many cases, he was told. If those who advanced money knew they would not get it back, it became a bonus, and gave a dangerous advantage to one estate over another. He was told the system was temporary, and he hoped it would soon be stopped. The present advance paid by the C. T. P. Co. was £16 per head. If the system were to continue the amount they would have to advance to retain their labourers would be very considerable, and the cost of producing tea must of necessity increase. He would like to add that he was very well pleased with the feeling amongst their superintendents in Ceylon. They had their estates in good order, and he believed they were proud to be Superintendents of the Ceylon Tea Plantations Company. (Applause.)

The motion was carried.

The CHAIRMAN proposed the re-election as a director of Mr. David Reid. This was seconded by Mr. W. Herbert Anderson and carried.

On the motion of the Chairman, seconded by Mr. D. Reid, Mr. G. A. Talbot was also elected a director.

The Auditors were re-elected on the motion of Capt. Fuller, seconded by Mr. W. M. Leake.

A vote of thanks to the Chairman closed the proceedings; the vote being made to include the staff in Ceylon, on the suggestion of Mr. Dangerfield.

[It is certainly no wonder that this premier Ceylon Tea Company should be considered to occupy a position of unequalled stability when, as its Chairman shows, the capital outlay only represents £22 per acre of tea! Recalling besides the profitable use made of the reserve in coconut plantations, the growing income therefrom and the extension of business towards desiccating mills as well as general Agency for small Companies and business concerns,—it is a question whether, even now, the shares are up to their real value. The high average yield per acre of tea is, as might be expected from the splendid condition of the estates as reported on by Mr. Talbot. This is still further shown, as well as the good management in field and factory, by the fact that the Company's teas realized rather better prices last year than in 1895, notwithstanding adverse exchange. We suppose of no other Company connected with Ceylon can this be said? Finally, the Chairman and Mr. Talbot made reference to labour difficulties and spoke out plainly about the upsetting of old arrangements by newcomers to the island anxious to get through a great deal of work and to gather together as much labour as possible on the spot. But we are not sure of this story and the inferences therefrom being altogether correct. At any rate, we have heard another version with quite a different appearance from the Visiting Agent of the new enterprise, who pleaded that the average of advances was, considering all things, fairly moderate. The Ceylon Tea Plantations Company, with its army of 9,000 coolies, has certainly a vital interest in maintaining the regularity and sufficiency of the labour supply on which the prosperity of Ceylon so greatly depends.—Ed. T.A.]

THE COCONUT MARKET.

The tone of the market shews a tendency to weakness, but high prices are still demanded for properties and there is an increasing demand for land for cultivation. In the Kurunegala District, the price per acre has run up to three or four times what it was about three years ago. The European market is flat for this line, and the bulk of our shipments find an outlet in America. It is said though, that there will be a less demand there for desiccated coconut from Ceylon before very long.

The market in copperah is also flat, and there is just enough produced for local consumption by the millers, while a few hundred candelies are purchased now for direct exportation by Messrs. Volkart Brothers. Prices in this line range from R32 to R43. Jaffna and Batticaloa copperah fetches the biggest figures. Oil is selling at R13 per cwt. (naked), and sellers are not very keen. The heavy drop in oil is attributed to the fact that a large quantity of tallow in Europe is admirably replacing our produce. In poonac (mill) the market is steady. Latest quotation is R65.

Nuts are selling at R35 to R40, with very little demand for them.

In the fibre business, the market is practically lifeless. A couple of years ago, there was a rush at fibre and yarn making, and everybody who could command a little capital went headlong to manufacture. Many were the little stations along the Negombo and Kandy roads where fibre was turned out. The stocks, were, of course, of all qualities, and in Colombo found many a purchaser who consigned the stuff to both the European and Australian markets. Most of the shippers were from the Pettah, and their stocks glutted the market in London so much that a heavy drop in price was inevitable. How the transactions turned out, the Pettah shippers will best be able to tell! Most of the "fibre mills" have stopped work, after teaching a capital lesson at some expense.

The immediate prospects of the market are poor, but there is sure to be a "turn in the tide" before very long.—*Cor. Local "Times."*

INDIAN PATENTS.

Applications in respect of the undermentioned inventions have been filed, under the provisions of the Inventions and Designs Act of 1888, during the week ending 24th April 1897:—

Improvements in tea dryers.—No. 157 of 1897.—Frank Edmund Winsland, tea planter, Joyhing, North Lakhimpur, Assam, for improvements in tea dryers.

The fees prescribed have been paid for the continuance of exclusive privilege in respect of the undermentioned inventions for the periods shown against each:—

Improvements in the method of an apparatus for drying tea leaf.—No. 80 of 1888.—Henry Thompson, engineer of Trinity Street, Gainsborough, in the county of Lincoln, for improvements in the method of and apparatus for drying tea leaf. (From 17th April 1897 to 17th April 1898.)—*Indian and Eastern Engineer*, May 8.

COCONUT PRODUCTS.

The announcement made of the probability of another establishment for desiccating coconuts being presently started in the Chilaw district, has some bearing on the position and prospects of the great coconut industry. Its development and extension within the last 15 or 20 years has been remarkable, if not phenomenal. Until 1890, after which year it was that desiccated coconuts began to have a place in the Chamber of Commerce Tables of Export, coconut oil was the chief, if not only, considerable product of the palm which was booked for export. To be sure, coir in its various forms of rope, fibre and bristles, and poonac, formed part of our exports for considerable periods; but even then aggregate value did not count for much. In later years, coconuts themselves, husked and unhusked, came to be exported to the Continent and the United Kingdom, but the highest record has, we believe, been during last year, when close on 14,000,000 nuts were exported. But even that represents but a fraction of our total produce of several hundred million nuts. As we have said, it is only during the present decade that desiccated nuts entered into our Export Tables; and yet from before that period the extension of plantations had grown to be considerable for several years. There can be no doubt that the desiccating business gave an impetus to the industry; but, as we saw in an article last January, the falling-off in the exportation of oil has more than counterbalanced the advantage gained through the new manufacture.

The total quantity of desiccated coconuts exported last year was over 10,000,000 lb. which would be equivalent to about 30,000,000 nuts. The falling-off in the export of oil, however, represents about 100 million nuts! Thus, last year we sent away only 343,000 cwt. of oil—the lowest figure for the past ten years, if we except 1887. In 1892 the exports amounted to 550,000 cwt. The difference, therefore, between 1892 and 1896 was as much as 217,000 cwt., and each hundred-weight of oil may be taken to represent 500 nuts. The present year shows no improvement in the demand for oil. On the contrary, there is a falling-off, though not very considerable, up to date; while the price has been about the lowest on record. The explanation of the last-mentioned fact is that tallow has been uncommonly cheap in Europe and in America, naturally affecting the demand for oil for soap-manufacturing purposes. Happily, India has come to the rescue, and taken away much more than America and the United Kingdom combined. And Singapore, too, has proved a good customer, having taken away over 15,000 cwt. as against 10,000 by America and 20,000 by the United Kingdom. The leap by India, from 16,000 for the first 4½ months of last year to 47,000 cwt. for the corresponding period this year, is promising; but still, both the total quantity of oil exported and the prices which rule, prove that the markets of Europe and America must govern prices; and the prices of nuts must be largely governed by the ruling price of oil. We are not of those who believe that the desiccating business has no influence on coconut prices. Such a belief is obviously untenable, in presence of the facts and experiences of the past few years. Still the 250,000,000 nuts which may be taken as a high average for the oil we export, must have a greater influence on the market than the 30,000,000 which the desiccating business represents. The fall in prices of nuts this year, as compared with last year, represented by R5 to R6 per thousand, illustrates and gives point to what we mean.

This fall cannot but be due to a very great extent to the restriction of business caused by the tightness of the money market. But for this stringency, we fancy Messrs. Akbar's Mills at Negombo would have continued to work—notwithstanding the sad death of their proprietor. One other establishment at least, not far from Colombo, owned by natives, has been obliged to stop work, owing to the stringency of the money market, during the whole of this year. Naturally, this has told on the local demand for nuts, of which the working mills took advantage. The resolution of the Orient Mills to have an establishment in the Chilaw district, supplementary to the large and flourishing concern which has existed for several years at Veyangoda, is in imitation of the example of Messrs. Vavasen & Co., who last year opened a branch establishment in the same great coconut district, where the ruling price for nuts is controlled to a great extent by the cost of transport to the port of shipment. Establishments like those we are considering take count of the lower cost of transport of the manufactured article—the cost of manufacture itself being lighter in the rural districts where labour is cheaper than in Colombo and the neighbourhood. A large proportion of the nuts of the Chilaw district, which found its way to Colombo in the shape of copra, will now go to the two desiccating mills there; and if copra becomes scarcer (and dearer) the re-

action must be in favour of nuts which will thus command a higher price! At least such is the hope of the coconut proprietor; while the calculation of the mills is said to be that prices will be easier, when the nuts of one district are not wanted for the manufactories of another. The reasoning would be intelligible if there is to be no advance in the quantity of desiccated coconuts; but so long as the new mills lead to larger exports, there must be keener competition for nuts, and with it better prices. Another fact which should cheer the hearts of coconut proprietors is the purchase of the Akbar Mills at Negombo by the Ceylon Tea Plantations Company. We suggested a couple of years ago, that this flourishing and wealthy Company, which has been investing its reserve in coconut estates, is not likely to be content with disposing of their produce to manufacturers. Its enlistment among manufacturers is to be welcomed by estate proprietors; and if only the demand for oil is fairly maintained, prices for coconuts may rise again to the figures of last year. But the oil market is ever a slippery one; and we would prefer not to prophesy before the event!

CEYLON AND ORIENTAL ESTATES COMPANY.

There is no indication in the Annual Report of the Directors of this Company—given on page 23—of a change of name as recently intimated in a local print. It will be seen that the Report is a full and satisfactory one giving due details as to selling price of tea, exchange, yield, &c., and the latest statistics of each estate as to cultivated area, &c. The dividend declared—aggregating 7 per cent for the year—must be considered satisfactory in view of the strong position taken by the Company with its 4½ per cent debentures. To have the Chairman of the Bank of England on the Board is a great advantage and no less to have Mr. Huntly Thring for Managing Director; while among the Directors are such well-known and esteemed names in Ceylon as Messrs. T. J. Lawrance, Reiss and Hancock. The Company has our best wishes for its continued prosperity.

FREE GRANTS OF LAND OFFERED IN BRITISH NORTH BORNEO FOR PLANTING.

We direct attention to the notice, in the daily issue of the *Ceylon Observer* from the British North Borneo Company, offering free grants of land to young men with a capital of £2,000 and upwards. The grants of land are of 500 acres each suitable for the cultivation of coffee, tea, cinchona, etc. Other lands suitable for tobacco, rhea and Indian rubber can also be had on favourable terms.

PRODUCE AND PLANTING.

LIBERIAN COFFEE.—The production of coffee in Liberia is increasing enormously. The coffee exported during the fiscal year, 1896, amounted to 600,000lb, while the exports for the year ended June 30, 1896, amounted to 3,000,000lb. Farmers, merchants, and people generally have turned their attention to

coffee growing. While no American ships touch at any Liberian ports, yet more than one-fifteenth of the coffee produced is shipped to the United States via Liverpool. Coffee is the largest export.

PLANTING IN SALVADOR.—As British capitalists are turning their attention to South America and its planting resources, they might favourably regard Salvador, says a correspondent. It is one of the richest countries in the world, and one of the most densely populated. There are no people of great fortunes like the Vanderbilts and Astors there, but a great many who have large estates that yield handsome incomes. Coffee is, of course, the big industry, and the crop is worth annually about 7,000,000 dols in gold. There is also a large amount of indigo exported. Almost the entire country is under cultivation. The only drawback to life in Salvador, and we should say it is a very serious one, is the constant dread of the ravage of yellow fever.

THE SPICE TRADE.—Ceylon cinnamon, notwithstanding the liberal supply and diminished delivery, shows a decrease in stock, and quotations are higher than they were a year ago. There are still plenty of cinnamon chips on hand, notwithstanding a decrease in the imports, and the value does not improve. The movements of black pepper at the port of London have been the very opposite to those in 1896, for whilst the landings during the first seventeen weeks of this year have been double what they were in 1896, the deliveries have fallen off by 220 tons, and the present stock exhibits an excess of 1,750 tons; but, strange to say, prices of Singapore and Penang are ½d to ¾d per lb above those in April last. White pepper, however, appears in a healthier position, as although there have been heavier landings, they have been largely outweighed by the quantity delivered, and the stock is 740 tons lighter than in 1896, thus warranting the rise of ¾d to 1d per lb that has been established on the leading sorts.

THE COOLIES OF JAMAICA.—There are about 10,000 East Indian labourers (coolies) in Jamaica, some of whom are still indentured upon the estates, and some of whom are now free. They are more intelligent and reliable workmen than the negroes. Without them it is claimed the managers of estates would often be at a loss to get their work done. The pure whites of Jamaica number about 12,000, and are chiefly British colonists and officials and their descendants, with a few hundred Americans.—*H. & C. Mail*, April 30.

NUWARA ELIYA TEA ESTATES COMPANY, LTD.

The first annual general meeting of this Company was held at Winchester House, 50 Old Broad street, on 30th April. Mr. C. A. W. Cameron presided. The Chairman in proposing that the reports and statement of accounts be adopted, stated that the Directors regretted that it was not possible to propose a dividend for the year at a higher rate than 6 per cent, especially as the first six months working allowed of an interim dividend being paid at the rate of 8 per cent per annum. But the rise in exchange, specially during the last six months of the year, the extensions to existing, and the erection of new factories, as also changes in the system of working, all combined to seriously interfere with the proper manufacture of the teas, and further, the later purchased estates were not at once in a position to do their share of profit-earning. However, the Directors were satisfied with the accounts under the circumstances, and hoped that the shareholders would also consider them as satisfactory, especially bearing in mind that nearly £1,000 has been applied out of the year's profits, towards writing off formation, expenses and cost of leases. The estates are now being brought rapidly into thorough order, and improved results are expected for the current year. The crop of tea to 21st April was 324,000 lbs against the estimate from all the estates

of 785,000 for the year, so that prospects were in favour of the estimates being exceeded. Besides the estates of Park, Concordia, Pedro, Larver's Leap, Kenmare and Naseby, and the leases of Fairy Land and Mazewood, the Co., had acquired Court Lodge with Excelsior, and Hillside estates. The area of land under tea was 2,174 acres, besides which about 60 acres, of good forest land was available for tea. The yield from the estates would increase as young tea came into bearing. The amounts £2162 15s 2d and £1,109 2s 1d would gradually disappear from the Balance sheet, as the Directors proposed apportioning a portion of each year's profits towards their liquidation. In conclusion the Chairman remarked that the carrying through of negotiations for the purchase of the estates had been a very difficult matter, owing to the great demand for Tea properties in Ceylon, and specially for such estates as those owned by the Company. The board was well satisfied that the Company was possessed of properties than which there were none better in Ceylon, and which should yield steady dividends.—Also that this Company is in a position, owing to the high prices their teas command, to meet possible set backs.

Mr. Oscar Thompson seconded the motion, which was unanimously adopted, and resolutions were afterwards passed declaring a dividend at the rate of 6 per cent. per annum on the ordinary shares; and the re-election of the retiring Directors, and Messrs. Cooper Brothers & Co. as auditors to the Company.

BRAZIL COFFEE NOTES.

A group of coffee plantations in S. Manoel, S. Paulo, belonging to the Queiroz family, has just been sold to a Dutch syndicate for the sum of £500,000. The sale of the Dumont plantations to an English syndicate, of the Queiroz plantations to a Dutch syndicate and the reported sale of another large property to a German syndicate, are significant indications of coming changes. If the government would reduce the tax on transfers, many small properties would also change hands at once, to the great advantage of the country.—*Rio News*, April 6.

THE COFFEE SITUATION.

Brazil coffee has dropped to the lowest point since 1886. The decline within one year has reached 6 cents per pound, and is due to increased supplies throughout the world. The full benefit of the lower prices has been given to consumers, largely through the war between coffee roasters. The result of lower prices is an increased consumption, which, for the first nine months of the trade year, shows an increase over the previous year of 362,163 bags.

The world is absorbing 1,000,000 bags per month and stocks are increasing. The visible supply of the world on January 1st, 1897, was 4,024,968 bags, against 3,552,792 bags at same date last year; on April 1st, 4,181,529 bags, against 2,634,670 bags on April 1st, 1896, an increase in one year of 1,546,859 bags—sufficient reason for a drop in prices.

An era of cheap coffee has been entered upon. Extreme low prices will check new planting enterprises, but we must bear in mind that 1896-97 marks the first tangible results of the last five years' extension of the planting industry.—*American Grocer*, April 14.

CINNAMON AND GRASS.

We direct attention to an extract from the local "Examiner," given on our third page, which affords some curious information. First, it appears that land cultivated with cinnamon near Colombo yields a return from two half-yearly harvests of R16 per acre per annum; while, on the other hand, land cultivated with grass—"Mauritius" or "Guinea"

grass, most likely the former,—within or near the city, gives a return of R8 per month or R96 per annum for each acre! Grass is, therefore, six times more profitable than cinnamon. How are the mighty fallen!

Now, it seems that the Government—or rather the Government Agent, W.P.—had recently to lease 300 acres of cinnamon and 200 acres grass for a period of five years (1897-1902) and how this was done, can best be learnt from our extract elsewhere. Suffice it to say, that while our contemporary estimates that the cinnamon should yield R24,000 in the five years and grass R96,000 or a total of R120,000, the 500 acres were at first, very nearly leased out for R20,000! But more sagacious counsels prevailed and the offer was raised to R55,000. Still, this is thought to be too low. But that depends. True, on the estimates, R65,000 will remain for the lessee; but what about his looking after 500 acres of cultivation for five years and the risk incurred, year by year, of a failure of crop or failure of market in that time. We scarcely think the margin too great from this point of view.

THE CEYLON & ORIENTAL ESTATES COMPANY, LIMITED.

REPORT OF THE DIRECTORS.

The Directors beg to submit the Audited Accounts for the year 1896.

The Tea crop (including 23,088 lb. made from bought leaf) totalled 1,542,754 lb. against 1,332,142 lb. in the previous year. The average price of the Tea sold in London was 8.07d. per lb., against 8.44d. per lb. in 1895, which depreciation is on a parity with that of the general average of Ceylon. The average exchange for the year was 14.68d. as against 13.56d. in 1895.

There has been charged to capital during the year the cost of the half-share of Denegama estate, and a small purchase of land at Keenakelle together with the sum of £1,320 2s 3d for new buildings and machinery, and £2,534 19s 7d for planting and upkeep of new clearings.

Upon renewals and repairs to buildings and machinery the expenditure was £1,125 13s 0d, and this outlay has, as usual, been defrayed out of revenue, while £500 has in addition been written off for depreciation. A liberal expenditure upon manure, considerably in excess of any previous year, has also been charged to the working account, and the full advantage of this has yet to be experienced. The estates have been well kept up in every respect, and according to the most recent reports are looking promising.

To provide funds towards payment of the second half-share of Denegama estate, an issue of £6,000 of 4½ per cent. First Mortgage Debenture Stock was made on the 1st October last. The price obtained for the stock was £103, and the premium thereon has been applied in part payment of the legal expenses and stamp duties attending the conversion of the 6 per cent. Debentures into 4½ per cent. Debenture Stock.

Owing to the higher exchange and a lower market for tea, the profits for the past year are less than in 1895. This deficiency was further increased by reason of the small crop of coffee from the 120 acres still in bearing on Keenakelle estate. The Directors are glad to say that a better revenue is expected from this source in the current year, as also from the increase of crop from the cocoa now coming into bearing.

In pursuance of the policy which the Directors have followed from the beginning, further small clearings of tea will be opened this year—in all about 100 acres.

The balance at credit of Profit and Loss Account, after paying all charges, including Debenture Interest,

writing off £437 12s. 11d., the expenses at tending the conversion of the Debentures, and £500 for depreciation of Buildings and Machinery, is £7,831 12s. 4d., and deducting therefrom the Interim Dividends paid in November last, there remains a balance of £1,945 3s 5d., which the Directors recommend be apportioned thus:—

To Reduction of Debenture Issue		
Expenses Account ..	£1,250	0 0
To Payment of the Preference Dividend for six months to 31st December 1896 (making 6 per cent. for the year), less tax ..	1,334	0 0
To Payment of an Ordinary Dividend at the rate of 4 per cent. (making 7 per cent. for the year), free of tax ..	2,210	11 2
To Carry Forward to next Account ..	150	12 3

The Directors again desire to express their satisfaction with the work done by the Staff in Ceylon. HUGH CHAPMAN, Secretary.

HUGH C. SMITH, Chairman.
J. HUNTLEY THRING, Managing Director
London, 24th April 1897.

CEYLON ASSOCIATION IN LONDON.

REPORT OF THE TEA AND PRODUCE COMMITTEE MAY, 1897.

The Committee has held six meetings during the year.

Special attention has been given to matters in connection with the public sales of tea in Mincing Lane so that the arrangements and conditions of the sales may as far as possible meet the convenience of buyers.

The limits for small breaks were extended to 18 chests, 24 half chests, and 40 boxes, on 1st October last; and these sales have since that date been of sufficient importance to attract buyers of every class.

At one of the large Tuesday sales of Ceylon tea, in October last, some delay was caused by the interposition between the large breaks and small breaks, of a sale of Java teas. On the attention of the Committee of the Tea Brokers' Association of London being called to this, a recommendation was issued by it to Java brokers to endeavour to induce their merchants to issue catalogues for Thursdays only.

In January last a circular was issued by the Tea Brokers' Association of London announcing that, in accordance with a resolution carried at the annual

meeting of the Association and with the concurrence of the London Wholesale Tea Dealers' Association the public sales on Moudays and Tuesdays would begin at 11-30 a.m., instead of 12 noon, on and after 1st February. This circular was quickly followed by a strong protest against the change, addressed to your Committee by twenty-one brokers and dealers, among them many leading men in the trade. The Committee considered the question as one mainly of convenience for those (brokers and dealers) who actually take part in the sales. The proposed change was not made and the Tuesday sales continue to be protracted to a late hour.

Much dissatisfaction has recently been expressed by the Wholesale Tea Dealers at the failure in many cases on the part of importers of Ceylon tea to comply with the requirements of clause 4 of the conditions of public sales, which states that the teas put up for sale have been "inspected" and "bulked (if necessary)." The Committee, having ascertained that the complaint made was not altogether without foundation, issued a circular letter inviting the attention of importers "to the imperative necessity for complying with the conditions of the clause referred to, so that buyers may operate with the fullest confidence in the future."

The Wholesale Tea Dealers' Association has since made a further request that in every catalogue each parcel shall be marked either "bulked in Ceylon," or "inspected and bulked in London."

In dealing with these matters connected with the public tea sales the Committee has been guided by the conviction that the interests of Ceylon producers can best be advanced by giving every possible facility and security to buyers.

Much damage was caused to the teas brought home last summer by the Orient Company's steamers "Anstral" and "Cuzco" owing to taint from apples carried in these vessels. Those who had suffered damage appealed to the Committee, who appointed a sub-Committee to deal with the matter. Protracted negotiations ended in a compromise, under which Messrs. Anderson, Anderson & Co., the agents for the Orient Company, agree to settle the various claims by a payment of three-eighths of their amount.

Messrs. Joseph Tetley & Co. brought to the notice of the Committee a case in which the Russian Customs authorities had charged a heavy duty on Acme tea chests entering Russia, as on tinplates, in addition to the duty payable on the tea packed in the chests. The matter was referred by the Committee to the Board of Trade, and a reply has been received from that department from which it would appear that in the case of large packages, such as chests or half-chests, tin casing is not liable to duty.

The Committee has watched with interest the constant increase in the demand for Ceylon teas in countries other than the United Kingdom. Mr. W. MacKenzie has attended several of the meetings and given information as to the progress made in the United States and Canada, while written communications have been received from Mr. M. Rogivue in regard to the growth of the tea trade in Russia, and from Messrs. Joseph Tetley & Co. as to prospects in Switzerland and the South of France. In each case the reports are encouraging.

The prosperity of the Ceylon tea industry has been well maintained during the year, though the profits of 1896 show, in many cases, some falling-off as compared with those of the previous year, owing mainly to the increased value of the rupee.—Local "Times," May 17th.

EASTERN PRODUCE AND ESTATES COMPANY'S MEETING.

The ordinary general meeting of this Company was held at Winchester House, London, E.C., on Wednesday, April 28th.

Mr. C. J. Lindsay Nicholson presided, and said that when he last had the honour of addressing the shareholders he was able to assure them that the

Company was prosperous, strong, and well. Today he was able to assure them that the Company was still better and in a stronger and more prosperous position. If they referred to the accounts it would be seen that the Company had some £55,000 to deal with, out of which all interest and liabilities had been paid. From the balance the Directors proposed to pay a dividend of 6½ per cent. for the year, to place £5,000 to the reserve fund, and to carry forward the balance of about £12,000 to provide for the debentures falling due during the year. The Company had expended slightly more on buildings and machinery, and, as was well said by a gentleman in that room last year, there was no inducement not to make good provision for the machinery, and each year they wrote off a good amount for the depreciation of machinery. The produce in hand on December 31st last was £21,495, which had all been realised at a profit. He could not help thinking that the position of the Company at the present time, in comparison with what it was at its commencement, was really surprising. Eight years ago, when the Company was started, they had debentures amounting to £200,000, carrying 6 per cent. interest, whilst at the present time they had only £100,000, at 4½ per cent. interest. The Directors could, if they desired, reduce that rate of interest, but they were more anxious to see the debentures cleared off entirely, and he believed that as time went on the Company would be able to pay off those debentures. At that time they had 8,000 acres of tea estates, whilst at the present time the number of acres under cultivation was 10,535. The reserve fund of the Company amounted at the present moment to £20,000. Eight years ago the average sale price was 1s. per pound, whilst today it was something a little over 7d. per pound. They had had a great deal of anxiety at times, and the success had not been unaccompanied by anxiety. If Ceylon tea was to continue to be prosperous it would be very necessary to keep up the quality of the tea. It was absolutely necessary that that should be done, and so keep them in the first rank to command good prices. It would not do for the Managers to be carried away by a loud boom, because after a boom invariably came a reaction, and they must use all their exertions to the making of good tea. At the present moment their factories and gardens were second to none and their Managers equalled by none.

The report was adopted, and the dividend approved.—*Morning Post.*

TANNING BARK AND ACACIA DECURRENS.—We attract attention to a letter on this subject elsewhere. At the recent Nuwara Eliya Show, Mr. A. J. Kellow exhibited Acacia bark on which he had a most favourable report from Colombo tanners, and a price which did more than cover expenses. But even here, the carriage of heavy bark must be the drawback, and "T" himself has pointed out to us the following paragraph which shows how that difficulty is overcome in Australia by the bark being "boiled down":—

"The bark of the Australian, 'black wattle' has been shipped from Ceylon experimentally from trees planted six years ago on estates as boundaries and break-winds. Each tree stripped gave 22 lb. dried bark. It is a question whether the value of this bark as a tanning substance will enable a price to be realised sufficient to do more than cover railway and steamer freight. In Australia the cost of carriage from the interior, where no water transport exists, is so heavy that the bark is there boiled down to a thick substance in a highly concentrated form, which of course reduces the cost of freight on the solid tanning principle. Were this system adopted in Ceylon, it might be found to effect a great saving in cost of transport."

Perhaps Mr. Kellow will give a trial to this plan in Ceylon and report the result.

LARGE BRAZILIAN COFFEE PLANTATIONS.

The largest coffee estates in Brazil comprises 110,000 acres of which 13,000 acres are planted with coffee, and 20,000 more are suitable for coffee trees. This plantation was sold to an English syndicate for \$5,338,000.

The United States Vice-Consul at Santos furnishes the following statement of the trees in bearing and of the yield and profits from 1892 to 1896 and estimated profit for 1896:

Year.	Coffee trees in bearing.	Yield pounds.	Profit dollars.
1892	.. 1,300,000	3,897,603	269,895
1893	.. 1,400,000	4,200,000	349,645
1894	.. 1,500,000	5,107,000	432,946
1895	.. 2,069,700	8,400,000	637,266
1896	.. 2,476,500	9,000,000	*711,133

Estimated.
The total number of trees in this plantation was, in June, 1896, 4,426,604, of various ages, including 194,000 planted in October and November, 1895, and it is estimated that two-thirds of the trees being new, from 1897 on an average harvest of 100,000 bags (13,200,000 pounds) may be expected, and that, when all the trees will have arrived at an age of three or four years, the yield may increase to 250,000 bags of coffee, or about 32,500,000 pounds per annum.

The next largest estate is owned by Carlos Schmidt, who arrived in Brazil from Germany some thirty-five years ago. The area of his property is 9,785 acres, with 1,800,000 trees, populated by nine colonies with 250 families, furnishing some 1,500 labourers. There are several other plantations on which grow more than 1,000,000 coffee trees.—*American Grocer*, April.

THE INDIA TEA TRADE.

Reuter informed us yesterday that a motion to reduce the duty on tea to 2d per lb. had been rejected by Parliament by 209 against 95 votes, a result which is not extraordinary, considering that the adoption of the motion would have involved a diminution in the revenue during the current official year of, roughly, 1½ millions sterling. The present duty on tea imported into the United Kingdom is 4d per lb., and the total imports during 1897-98 are estimated at 270 million lb., which gives £4,500,000 as the amount of the duty to be received. The Chancellor of the Exchequer has estimated for a surplus during the year of £1,569,000, so the reduction of the duty on tea would have swept away all this, as well as a further largessum, assuming, that is, that the estimates were not exceeded. The advocates for the reduction of this duty have been rather too precipitate, and placed their demands too high. If they had moved that the duty should be reduced a penny per lb., it is possible that success might have crowned their endeavours to secure this further and important advance towards a "free-breakfast table." The time may come when this will be brought about, but it is not yet. Since 1711, the duty on tea imported into the United Kingdom has been altered very many times. Commencing in the above year at 5s 6d per lb., it continued that figure until 1750 when it was reduced to 3s 4d. In 1760 it was reduced to 3s and to 2s 6d in 1770. In 1780 it was raised to 3s 4d, but in 1790 it was reduced to 7d. In 1800 it was increased to 1s 6d and to 3s 10d in 1810, but in 1820 it was reduced to 3s 2d and at the end of the four following decades the duty was as follows:—2s 6d, 2s 1d, 2s 2d and 1s 6d. In 1870, the duty was reduced to 6d, at which figure it remained until 1890, when it was reduced to the present figure, 4d per lb. As regards the average price of tea per lb. in the United Kingdom, it has fallen from 18s in 1711 to 9½d in 1896, while the consumption has risen in the same period from 142,000 lb. to 258,000,000 lb., the record, which will, if the estimates are worked up to, be largely exceeded during the current year.

We have in previous years contrasted the remarkable increase in the production of British-grown teas with the equally remarkable decline in the production of China teas, and the partly estimated returns for 1896-97 show a continuance of the one and the other, for while the former figure at 223,000,000 lb., an increase over the previous year of about 22,000,000 lb., the latter figure at 35,000,000 lb., a decrease of about 6,000,000 lb. The following statement, compiled from Messrs. Geo. White & Co.'s interesting annual report, showing the fluctuations in the production of tea, is instructive:—

	India.	Ceylon.	China.
1875-76 .. lb.	25,500,000	200	149,000,000
1885-86 .. "	67,250,000	5,361,000	143,000,000
1895-96* .. "	118,182,000	83,388,000	40,859,000
1897-98* .. "	135,000,000	100,000,000	30,000,000

* Estimated.

As regards last year's crop of Indian tea, the quality appears to have been ordinary, with some very choice descriptions in the autumn, and the average price for eight months was 9½d, compared with 9d in the same period in 1895 96 and 10½d in 1894 95—the Ceylon average for those periods being respectively 8½d, 8½d and 9½d. During the current year, no advance in price is anticipated, and Messrs. Geo. White & Co. consider that the tendency is to a lower range, the demand being for a cheap, i.e., low-priced, tea, a large proportion of the imports going into consumption at the retail price of from 1s to 1s 4d per lb., while 1s 6d to 1s 8d is considered a liberal figure for the better descriptions. This being the case, and with a possible higher rate of exchange, this firm regards it as "more than ever a matter of necessity that the sale of British-grown tea should continue to be pushed in countries other than Great Britain with all possible vigour." Much has already been done in this direction, and the shipments of India tea to Australia, to countries in Asia, to America and to the Continent of Europe have increased from 9,406,000 lb. in 1894-95 to 12,648,000 lb. in the past year. But this is not sufficient, especially as the exports to the same countries from Ceylon have increased in the same period from 9,091,000 lb. to 14,532,000 lb., the exports of Australia last season having been very nearly double those from India. The great Indian and Ceylon Tea Associations have worked with a will in the past to push sales in new fields, but it is of paramount necessity, as Messrs. George White & Co. remark, that their efforts should be persisted in with even greater stress than heretofore if they do not wish prices to fall, owing to the supply exceeding the demand.

India and Ceylon may again have a formidable competitor in China, where modern machinery and modern systems of manufacture may shortly be introduced. What the ultimate result of this up-to-datedness on the part of China will be, remains, of course, to be seen; but from the opinion which tea-brokers in the United Kingdom have expressed about some of the "new-process" tea from Foochow, the reformed methods of manufacture may exercise a powerful and maleficent influence on the consumption of the British-grown article. From a circular issued by Messrs. F. Cave-Thomas & Co., of Foochow, we learn that Messrs. Andrew Melrose & Co., an old established firm of tea dealers in Edinburgh, have stated that "if John Chinaman sends Home all his tea as strong as this"—a sample of the machine-made tea which had been submitted to them for their opinion—"he will very soon give a good account of himself against the overwhelming flood from India and Ceylon, because there is in this sample much more of what the public consider the style and taste of tea than much of the woodytasted stuff that comes from many of the Indian estates especially." This sample, it appears, was ordinary third-crop Peking leaf, and it is fondly anticipated by a China paper that first-crop leaf from the leading districts in the Yangtze Valley, prepared according to the new method, would be infinitely superior thereto. A Shanghai firm in commenting on the enthusiastic manner in which

this "new process" tea from Foochow was received in England and reported upon by leading distributors, states that there is a "strong hunching for something in tea which is lacking in India, and only partially found in Ceylon produce. This something is the 'flower' flavour which only China leaf possesses, and our opinion is confirmed that China leaf made by machinery would be the ideal tea that is wanted. The market is ready for it as soon as it is produced." These no doubt, are the opinions of those whose interests are chiefly centered in China tea; but there can be little doubt, we think, that, given such a strong tea as that referred to, India and Ceylon will have to look to their laurels. However, the time is not yet to despair—there is a peculiar excellence in the British-grown article which will require a deal of beating, and that is, a little goes a very long way, a fact which appeals strongly to the public.

That the method of manufacture in India and Ceylon is not perfect is shown in Messrs. Geo. White & Co.'s report, where they state that "there is still room for the application of science to some of the stages of withering, fermentation and drying." And in view of the large quantities of leaf that are spoiled for want of knowledge in the details of curing, they repeat the suggestion which they made in 1883, that a specialist should be appointed to experiment with a view to afford information to garden managers in these points. The *Produce Markets Review* has also expressed the opinion that it would amply repay planters to engage the best scientific assistance to study the chemical constituents of the leaf under different conditions of soil, weather and blights, also of the various changes it undergoes in withering, drying, rolling, etc. With reliable information on these points, uniformity of quality throughout the season might be secured, and violent fluctuations in value thereby avoided.—*M. Mail*, May 13.

MISSIONARY COFFEE PLANTATION.

Bishop Hartzell, of the Methodist Episcopal Church, is now visiting the missionary stations established by Bishop Taylor on the west coast of Africa. In a letter to the *New York Christian Advocate*, Mr. Hartzell says: "The movement inaugurated by Bishop Taylor ten years ago for a great advance among the native heathen of Liberia will stand out in history as one of the really heroic movements in missionary annals. In ten years fifty stations were opened and eighty-eight missionaries brought from foreign countries, most of them being from America. In the effort toward self-support fully 45,000 coffee trees have been planted, and large expenditures made in the way of stock, fencing, sugar mills, transportation, etc. Of the fifty stations opened twenty-nine are now occupied. Two which had been opened on the east side of the Cavalla River were abandoned because of the French taking the territory. Of the twenty-nine now occupied fully one-half, for lack of workers and means, are doing but little. Of the 45,000—probably 50,000—coffee trees planted, scarcely 15,000 have been saved being choked to death by grass and bushes. American farmers can have no conception of the abundance and rankness with which vines and bushes grow in this country, or with what rapidity buildings will disappear. Leave a well-cultivated farm to itself three or four years, and every vestige of the buildings, except the stones and the few hard native timbers used, will be gone, eaten by insects; and the land will be one mass of vines and bushes, so intertwined and tangled that to pass through them is impossible, except as natives cut the way before you. It requires much labour and expense, as well as business push and judgment open and maintain a coffee farm in Liberia. "I have visited our best stations, and made diligent inquiry of those in charge of others to find out how much coffee will probably be sold from the twenty-nine stations now occupied this year. The amount will certainly not exceed \$200, and half of that from Barraka, our best station."—*American Grocer*, April 14.

THE AMSTERDAM BARK MARKET.

One Amsterdam correspondent writing on April 27, states that at the Java cinchona-auctions to be held in his city on May 6th, 5,691 bales and 233 cases, weighing in the aggregate 524,362 kilos of bark will be offered. They represent a total of 28,892 kilos of sulphate of quinine, or an average for the Manufacturing bark of 5.60 per cent, which is above the average. The Pharmaceutical bark consists only of 17,255 kilos, representing 485 kilos of quinine. The general position is extremely firm, and it is expected that there will be a very good competition at the sales, and that the unit will again exceed that of the April auctions. Provided the April shipments from Java remain moderate, there will only be sufficient first-hand stock in Amsterdam to provide for small auctions in June and July. At present it would seem that there are only small Java shipments in prospect. The demand for quinine is said to remain very good and rumours are current that the price will again be advanced. The next cocoa-broker auctions will consist of 40 tons of Van Honten's, 10 tons of Hamer's, 10 tons of Dutch factory, and 7 tons of foreign brands. The market is firm, but the demand is small.—*Chemist and Druggist*.

COFFEE MILLS.

Brazil.—Coffee mills have a very wide sale in this country. Formerly they were largely of French origin, but we have now been distanced by Germany, owing not so much to cheapness as to the active way in which the Germans push their trade.—*French Consul at Sao Paulo*, August 30, 1896.

ANNUAL REPORT OF TEA SALES IN MINING LANE.

A planter writes:—"Messrs. Wilson, Smithett & Company's big list is very interesting reading, but there are evidently several rather large errors of quantity. Could not this be remedied by getting the quantities checked by the selling brokers for the several estates before printing?"—Certainly this ought to be done.

COFFEE.

HAWAIIAN ISLANDS.—Under the provisions of the Land Act, 1895, a large area of Government land has been leased to small holders, with privileges of home-steading and eventual purchase, principally in view of its probable adaptability to the cultivation of coffee. The experiment is still in process, as a year or two more must elapse before any considerable result of systematic planting can receive a fair test.—*British Consul-General at Honolulu*, Nov. 29, 1896.

COPRA.

Zanzibar.—The cultivation of copra is still gradually increasing, the owners of plantations probably finding that, in view of the very small amount of attention that has to be bestowed on the growth of the coconut tree, the increasing scarcity of labour, the absence of any duty on this commodity, and the low price of cloves, the production of copra is as remunerative to them as that of the last named article. France takes practically the whole of the copra produced, a small quantity going to Germany and very little elsewhere. English merchants, who in former times used to transact an extensive business in this direction, state that they cannot attempt to compete with the prices that are now readily paid by French and German houses.—*British Consul at Zanzibar*, May 23, 1896.

THE SPIRITS OF Cinchona Planters must be rising. Since February the price of the bark has gone up about 45 per cent.—*Pioneer*.

THE CINNAMON GARDENS LEASE

1897—1902.

A HINT TO THE GOVERNMENT.

The mistake that Government may make in sanctioning leases of Crown lands with only imperfect and untrustworthy information is upon us never better illustrated than in a recent instance when it was asked to part with some six hundred acres of land in the Cinnamon Gardens, in the Colombo district of the Western Province for R20,000 for five years from March 1897. The Government it seems was almost persuaded to approve of the offer; but most fortunately it resolved to call for tenders; with the result that, instead of R 20,000 it secured R 55,000 an increase of R 35,000. We learn that had notice of this sale been published in the local papers, and had the lands been properly described as being partly under grass and partly under cinnamon, and definite information given as to the acreage under each instead of the lands being vaguely called "cinnamon lands," the price they would have realised would have been not R55,000 but over R100,000. From information which has reached us, the value of the lease for 5 years appears to be nearer R120,000. The nett return from an acre of grass or cinnamon land it is well-known is between R8 and R10; the only difference is that in the case of grass the return is a monthly one, and that in the case of cinnamon it is half-yearly. This being so, and taking the acreage under grass and cinnamon at the figures reported to us, namely 200 and 300 acres respectively, the nett profit from 200 acres of grass at R8 per month for five years amounts to R96,000, and the nett profit from 300 acres cinnamon at R8 per acre, as the cutting is half-yearly, amounts to R24,000 making a total of R120,000. In the face of these facts what shall we say of the private offer made to Government of R20,000 for 5 years which it narrowly escaped accepting? In this connection we should like to know why no stress was laid by Government when it called for tenders, on the important fact that half the area of the "so-called Cinnamon Gardens" is now, and has been for years past, under grass. Fortunately grass has proved a good substitute for cinnamon, and it is well that it is so; but it is to be regretted that the Government and the public were not aware of it earlier, or both would have benefited. Evidently it was to the advantage of interested parties to keep this information to themselves. Surely these valuable lands should not have been disposed of in this careless fashion. We cannot help thinking that it would have been greatly to the interest of Government if, before it completed the lease even on tenders it had called for a special report from the Mudaliyar in whose division these lands are situated. Government might then have been in a position to place a reserve price on the lease, and got at least R100,000 instead of R55,000. We hope when these lands are next put up for sale, that not only will this officer be consulted; but that the Government will be in a position to tell the public the exact extent of land under grass cultivation and the exact acreage under cinnamon. These lands were originally all under cinnamon, and the price of cinnamon being subject to fluctuations, they were not much in demand. The case is quite different now. Owing to half the acreage being at present under grass, they are now worth 10 times what they were worth 10 years ago. We wonder who is responsible for not pointing this out. We hope Government may be more fortunate at its next sale, and that it will take every precaution in time to find out as closely as possible what these lands are worth without disposing of them in an offhand manner and summarily by tenders as was done with the lease for 1897-1902. We would suggest that, instead of waiting till the lease expires in 1902, the Government should at once appoint a strong Commission consisting of say the Hon. the Auditor-General and the Hon. the Acting Government Agent of the Western Province to find out

what this lease is *now actually worth*, so that it may be in a better position to deal with this matter when it come for disposal in 1902. One reason, we are informed, why people were unwilling to tender for the current lease was that they feared that they would be harassed after they had secured the lease, as were the parties who cleared the 200 acres of cinnamon now under grass, and be involved in endless and expensive litigation.—Local "Examiner" May 18.

THE AMERICAN PEOPLE AND GOOD TEA.

The American people are congratulating themselves that, under their new tea regulations at the Customs, they have seen the last of "cheap and nasty teas." The American *Grocer* of April 27th says:—

"If the recommendations of the commission are adopted we shall have few, if any. Pingsuey teas; neither will we have any more of those low-grade Amoy Oolongs which have perplexed this market for years. The displacement of China tea in the United Kingdom by Ceylon and India teas stimulated the importation of trash into the United States. We believe that the high standards adopted will result in an increased consumption and that they will also tend to improve the manufacture of the leaf both in China and Japan. The following standards are established:—

No. 1—Formosa Oolong; No. 2—Foochow Oolong; No. 3—Amoy Oolang; No. 4—North China Congou; No. 5—South China Congo; No. 6—India tea; and No. 7—Ceylon tea.

(In each of the above standards the maximum percentage of dust and fannings must be restricted to 10 per cent when sifted through a No. 16 sieve, inasmuch as any excess over this percentage of dust and fannings is liable to be made up of extraneous matter.)

No. 8—Pingsuey green tea. (As this standard is of better make or style than was necessary to represent the quality of infusion, the rule must be specially emphasized to examine with reference to liquor and infused leaf only.)

No. 9—(a) Country green tea; No. 10—(b) Country green tea; No. 11—Japan tea, pan-fired; No. 12—Japan tea, sun-dried; and No. 13—Japan tea, basket-fired.

(Dust and fannings in last three standards not to exceed 40 per cent.)

No. 14—Japan tea, dust or fannings; No. 15—Scented Orange Pekoe; and No. 16—Capers.

It is understood that the comparison of the standards with teas delivered must be made upon the drawing of the tea as well as the appearance of the leaf after infusion, and that little or no consideration will be given to the make or style or colour of the teas in the dry leaf."

We trust Colombo shippers will take very great care not to incur censure or rejection for any of their teas at the hands of the American Commissioners; for, the fact would be notified far and wide, and do Ceylon teas great harm. Twice has Ceylon tea—no doubt from native gardens—been rejected at Melbourne as "unfit for human food," and we do not want the same thing to happen at New York. One of the Commissioners, Mr. Phelan, has been remarking:—

Although the world has drunk tea for ages, very little is known about it by the average consumer. For instance, there is a popular superstition that green tea is prepared on copper, from which it derives a deleterious flavor. This is erroneous. Green tea is prepared like all other teas; although there is a minute quantity of coloring matter used to give to its peculiar shade, it is composed of a harmless substance, and in

so small a quantity that one or two teaspoonfuls will color a whole package. All the prejudice which heretofore has existed against deleterious mixtures in teas will hold good no longer, as every leaf imported is guaranteed to be pure, and there is not an article of merchandise produced in our own country which can be mixed with it without transforming its character.

And then we have the following statement from the editor:—

It is interesting to note how the various sections of our country adhere to their different teas. For instance, New York City and Boston take almost exclusively Oolong teas, and as the Amoy teas, which are the lowest grade, will probably be excluded largely under the new law, these cities will obtain Formosa Oolong principally in the future. The Eastern States are likewise consumers of Oolong tea, whereas in the Northwest covering Minnesota, Michigan, Iowa, and Wisconsin, the consumption is exclusively of Japan tea. Twenty-five years ago these same States took exclusively green tea, but owing to the greater uniformity of Japan tea, have gradually preferred it to any other. The Middle States, such as Missouri, Indiana, Illinois and Ohio, are large consumers still of green teas, using principally Gunpowders, Imperials and Young Hysons. Likewise, in the Southern States, with this difference, that in the South the consumption of tea is almost nominal, the whole South not taking as much as New York State alone. Congou tea is used principally by more recent emigrants and also by the descendants of the English and Irish races. This was the tea used in England for many generations exclusively, and recently supplanted by India and Ceylon tea, which are similar to Congou, or English breakfast teas in flavour. Therefore, while it is taken as a substitute for the latter in England, Ireland and Scotland, it moves much more slowly in our country, as we have never been consumers of that description of tea to any extent, being described by most Americans as "weedy" in flavor. It is a remarkable fact that while Russia has a very heavy duty on tea of over 40 cents a pound, she consumes the choicest Congou in the world to the exclusion of all other kinds of tea. Hence these teas are frequently called "Russian," and obtain an indefinite *et cetera* in this country from the uninitiated. There is a duty of 8 cents per pound in England, but none whatever in America. Hence our tea is the lowest in price in the world, and hereafter will be the best in average quality.

It ought to be brought home to our American cousins that the Australians, who are the largest consumers per head of tea (chiefly Ceylon and Indian) in the world, are also among the most athletic, excelling in cricket, riding, and other physical exercises; and indeed our American friends have yet fully to understand that the properties of coffee (which they consume so largely) and of tea are, in the last resort, very much alike.

A GEOLOGICAL SURVEY OF CEYLON.

Fully twenty years have elapsed since we first pressed this very desirable work on the Government of Ceylon. Sir Wm. Gregory and Sir Arthur Gordon most fully acknowledged its importance; but each procrastinated until the end of his term of government was upon him. We trust better fortune is to attend Sir West Ridgeway who, we feel sure, from his knowledge of the great value, in an economic point of view, of the Geological Survey of India, must feel the special need of such an investigation in Ceylon. Mr. W. King, brother of the Government Agent for the North-Western Province, and who rose to be head of the Geological Survey in India before his retirement, was very eager, after several visits to the island,

about a Ceylon Survey, and thought it could be managed by one or two officers lent by the Indian Government, at no great expense or loss of time. The conditions in Ceylon over large districts make a Geological Survey comparatively easy. Nevertheless, our Governor may plead that he cannot face a Cadastral and Geological Survey at the same time; and yet the later is a far simpler and cheaper business. On the other hand, we learn from reviews of the India Geological Surveyors' Report for 1896—*which must have been published early in March*—that the Indian Staff is at present shorthanded. Owing to retirements, furloughs, etc., there were only six officers available for the whole of India. But, we suspect if it were made known that the Ceylon Government wished to borrow a couple of Geological officers, men on furlough would gladly come forward on the chance of a spell in this interesting and comparatively healthy island. Be that as it may, it is quite evident that a Geological Survey of the colony ought to be no longer delayed. The great industry in plumbago alone—our one mineral so far of commercial importance—more than justifies such a Survey. The exports of plumbago have developed as follows:—1850, 28,823 cwt.; 1860, 75,660 cwt.; 1870, 85,219 cwt.; 1880, 205,738 cwt.; 1890, 392,577 cwt.; and 1895, 326,754 cwt. But the exploiting of plumbago deposits is done entirely by the Sinhalese without any scientific guidance. No one knows how great may be the rich deposits that a Geological Survey might bring to light within certain untouched areas, and as the Ceylon Government draws a royalty of Rs5 on every ton exported, it has a most practical and direct interest in extending the industry. Secondly, there are gem deposits famous from the time of Solomon; yet never surveyed nor mapped out, though one or two localities have been examined and reported on most favourably by English experts. With the new patented machine of Mr. Lockhart, which we saw tested in London, we cannot see why there should not be a great development of gemming under European capital, if only the proper tracts of country on which to operate were authoritatively pointed out. Here again the Government, through licenses and leases, ought to get its full share of revenue. This may be said to belong more particularly to a Mineralogical Survey; but a Geologist with Indian experience would be sure to know a great deal about Mineralogy.

Still, a third incentive to commence a Geological Survey at an early date is found in the value of the iron ore deposits scattered throughout Ceylon. Dr. Davy, brother of Sir Humphry Davy, found the ore in the Kandyan provinces to be so rich in iron as to yield 70 and even 90 per cent; and we have most of us seen the remains of Sinhalese smelting places notably in and about Nuwara Eliya. But it is in the Sabaragamuwa and Balangoda districts that commercial importance may be attached to our iron deposits, if it be true, as reported by Dr. Gygas more than fifty years ago:—

"The varieties of iron met with are six in number: viz., magnetic iron ore, titanate of iron, chromate of iron, iron with manganese, iron pyrites, and yellow hydrate and red peroxide of iron. The iron, however, in most of these is scanty, and the ore of little value except to extract the chromo and manganese. But there is another description of ore found in vast abundance, brown, compact, generally in the state of car-

bonate, though still blinded with a little chrome, and often with molybdena. This occurs in large masses and veins, one of which I believe extends for a distance of 15 miles. Of this, millions of tons might be smelted, and when found near water-carriage and fuel it may be worked to a profit. I would lay particular stress on the very fine quality of the iron ore found in Ceylon, it is easily smelted, and so pure when reduced, as to resemble silver. The rough ore produces from 30 to 75 per cent—on an average fully 50 per cent the iron wrought from it requires no puddling, and steel thus made cuts glass like a diamond.

It appears that Spain is rapidly getting poorer in iron ores, and we were assured in London that if Ceylon ores lay within easy reach of a navigable stream, it would pay to carry the same to London or Glasgow—freight being so very cheap—there to have it smelted and manufactured.

We think we have said enough to make out our case for a "Geological Survey." It ought not to be expensive or tedious; it ought to be directly remunerative; and it ought to be the means of extending old and developing new industries—and industries too, of an eminently desirable character in a country hitherto so dependent on its Agriculture and Planting—with their varying fortunes—as is Ceylon.

SCIENCE AND PRACTICE: PLANTING AND ENTOMOLOGY:

THE WORK OF MR. KEBELE, ENTOMOLOGIST, IN HAWAII—AND HOW FAR IT BEARS ON PLANTING IN CEYLON.

A recent number of that very useful publication, the Hawaiian "Planters' Monthly," contained a special Report on his work as Entomologist, from Mr. Albert Kœbele. It is long and technical, and may be deemed too dry and scientific for perusal by the general reader; but we have reproduced it in our daily and *Tropical Agriculturist* for the benefit of our planting community. There are not a few thoughtful planters, we are glad to say, still in the island and to them the account of Mr. Kœbele's work among the "poochies" and other enemies of planting and agricultural industries, will not be uninteresting. Hawaii is as great a paradise for insect and fungoid life as is Ceylon; but there are striking differences, because we find Mr. Kœbele endeavouring to introduce such enemies of insects as rats, bats and toads. And without success, too, in the early trials, as regards the first and second, though there is hope that the batrachian introductions may get on. Now, we need scarcely say that there is no lack in Ceylon of such enemies of insects as are above detailed. Indeed rats were at one time a great enemy of the coffee-planter in certain districts. When their food in the jungle—the *nilu* plant for instance—failed them, rats sometimes invaded the nearest coffee plantation and nipped off the primaries or secondaries of the bushes, thus inflicting a terrible loss on the owner. Such experiences however—as indeed, alas, coffee itself almost—are things of the past in Ceylon; for, we have not heard of a single case in which rats have attacked our later staple product, tea.

We naturally referred Mr. Kœbele's Report to Mr. E. E. Green, who has been good enough to supply us with a series of "Notes" pointing out the portions, and the enemies, which have a direct interest to Ceylon planters. This we append

as an admirable summary for local use of the full Report. But, before doing so, we may quote from a very interesting letter accompanying "the Notes," which has remained by us too long:—

Etou, Punduloya, 19th April.—I return your copy of "The Hawaiian Planters Monthly," containing the Report of the Government Entomologist (Mr. Albert Kœbele). This whole Report goes to show what can be done by an intelligent man—with a knowledge of his subject—who can give his whole attention to the work. Not that everyone would have succeeded as admirably as did Mr. Kœbele. He seems to have been the man most exactly fitted to the task.

It may be said by sceptics that this glowing account of his success is merely the man's own testimony. But there is ample outside witness to the value of his work. In a recent number of "Nature" (25th March '97), Mr. R. C. L. Perkins—the Naturalist deputed by a Committee of the Royal Society and British Association to investigate the Fauna of the Sandwich Islands—speaks in the highest praise of the results of the introduction of beet and their insects into the Hawaiian Islands.

I have just received a letter from Mr. Kœbele himself in reply to my question as to whether he would be in a position and willing to undertake a similar work in Ceylon.

It appears that the Madras Government has also approached Mr. Kœbele on the subject.

With respect to Ceylon, Mr. Kœbele writes:—"If the Ceylon people should want me, my services would be required in India also . . . It would suit me to introduce all enemies I know of for any scale pests you may have in the respective places. I could do it—alone—in about two, at longest three years. I may be able to come at the beginning of next year if so desired—not permanently, but only for the time stated."

Mr. Kœbele does not answer my enquiries as to the cost of the undertaking and the remuneration for his services. I am writing again to ask for some estimate. In one respect I think Mr. Kœbele misunderstands the position. We do not require such a general and varied introduction of different species as has been carried out in the Hawaiian Islands, covering a long period and occupying the continued attention of the specialist. All we want at present is to see the one or two species of lady-bird beetles that are most likely to help us against our dominant pest ('green bug', *Lecanium viride*), properly established in Ceylon. This could certainly be effected within a very much shorter time than that suggested by Mr. Kœbele. As I mentioned in one of my former letters, I do not advocate any very extravagant outlay in the experiment. I am now of opinion that the decay of coffee was not by any means entirely or even mainly due to the ravages of the bug, though the bug hastened the downfall by sapping the system of the trees already weakened by other—more deeply seated—causes, of which leaf-disease was the prime factor, backed up by a reckless waste of surface soil.—E. E. GREEN.

We quite agree with Mr. Green that Mr. Kœbele takes an exaggerated view of what is required in Ceylon, and indeed he must learn that the cultivation of "Coffee" has been so reduced in area in Ceylon—only a few fields in a few districts being left amidst the universal "tea"—that the support available for the introduction of the enemy of "green bug," is very limited. The same may be said of Southern India: only in Coorg and Mysore is there an appreciable quantity of coffee left. Our proposal was that the planters of Southern India and Ceylon should unite, getting aid from their Governments, in making up a suitable fee and the necessary expenses for Mr. Kœbele. If his mission proved successful with us, it is very likely that further profitable commissions might await him, especially from Java, Sumatra, and the Straits Settlements. But he must know

that nowhere in the East is coffee, "king now-a-days.

The practical "Notes" with a local bearing, supplied by Mr. Green on Mr. Kœbele's Report, are as follows:—

NOTES UPON THE REPORT OF THE
ENTOMOLOGIST OF THE HAWAIIAN
GOVERNMENT.

1. *Dactylopius ceriferus*.—Not uncommon in Ceylon; usually in insufficient numbers to be serious. But I have quite recently noticed a really bad attack of this blight in Colombo, where the insect was so abundant on several ornamental shrubs that the plants were quite disfigured and parts of them actually killed.
 2. *Dactylopius adonidum*.—Though it is doubtful if the species has been rightly determined (I believe its correct name to be *Dactylopius citri*); this is the "mealy-bug" long known as a coffee pest in Ceylon.
 3. *Pulvinaria psidii*.—Very abundant in Ceylon. It has seemed to me to have considerably extended its range within the last few years. I first noticed the pest to a few years ago upon cinchona. I next found it established upon tea; and I constantly find it now upon individual tea bushes which are completely blackened by the accompanying growth of fungus. Fortunately, it does not spread much upon tea. The species is almost constantly present upon guava trees. Orange and lime trees are much subject to its attacks. I could give a long list of ornamental shrubs in the garden and wild plants and jungle trees upon which I have noticed the pest. At present some *Aralia* plants in my garden are literally covered with the insects. In fact, the species is fast becoming omnivorous. Curiously enough the coffee plant, which is so badly affected by this pest in the Sandwich Islands, is one of the few Ceylon plants upon which I have not found the insect.
 4. *Lecanium acuminatum*.—Under this name Mr. Kœbele is referring to a largish triangular flat scale that is sometimes rather injuriously abundant upon mango trees in Ceylon.
 5. *Aspidiotus awrantii*.—Present in Ceylon; but not so far noticed in injurious numbers. Our climate appears to be too tropical for its comfort. As Mr. Kœbele points out, the species flourishes better in more temperate latitudes.
 6. *Aspidiotus eydonie*.—Common on many different plants, especially upon fruit trees of various sorts, where it seems to appreciate the fruit itself. I have seen the rind of a pomelo fruit so thickly encrusted with the scales that the natural surface was completely obscured.
 7. *Aspidiotus camellie*.—A common and distinctly injurious pest upon tea and cinchona in Ceylon.
 8. *Pentatonia zizyphi*, and *P. pergandei*.—It is surprising that neither of these two species has yet been recorded from Ceylon. They are both very common pests of orange trees and have been introduced into most countries where oranges are grown, being very easily imported upon the rind of the fruit. We probably owe our immunity to the fact that we rest content with the old original varieties that have been cultivated here from the earliest times, without attempting to improve the strain by the importation of plants or seed from other countries.
 9. *Mytilaspis citricola*.—Common on orange trees in Ceylon.
 10. *M. gloveri*.—Collected from orange trees in Kandy.
 11. *M. pallida*.—Common on several wild shrubs in Ceylon. Found also occasionally upon guava trees.
 12. *M. pomorum*.—The only living examples of this insect that I have seen in Ceylon were upon the rind of imported Tasmanian apples. In England the species has become almost omnivorous. The species does not appear to flourish in the tropics.
 13. *Chionaspis biclavus*.—This species is nearly always present often in injurious numbers—upon the stems of cinchona and tea plants. It is a very inconspicuous insect and escapes general observation from the fact that the colour and texture of the scale is wonderfully adapted to the surface upon which it rests.
 14. *C. eugenie*.—Some scale-insects found upon *Litsea zeylanica* and several other jungle trees were determined by Mr. Maskell as varieties of his species *C. eugenie*. It is not a species that is likely to prove of economic importance.
 15. *Diaspis amygdali*.—Very abundant on many trees and plants in Ceylon. It is a common pest of geranium plants—(see 'Coccidæ of Ceylon', part I. p. 68).—I have lately noticed that it has established itself upon the stems of one of our common shade trees, the 'Dadap' (*Erythrina* sp.).
 16. *Fiorinia camellie* (= *F. fiorinæ*).—This species has been noticed upon tea in Ceylon this year for the first time. It is a minute insect, and though present in considerable numbers, it does not seem at present to have materially affected the health of the plants.
 17. *Ceroplastes rubens*.—Occasionally present upon tea.
 18. *C. floridensis* is also found (rather commonly) upon tea and other plants; but does little or no harm.
 19. *C. ceriferus*.—Quite a large species, measuring sometimes nearly half-an-inch in diameter; common upon many wild plants; and occasionally present upon tea stems. The insect produces such masses of waxy matter that experiments have been made to test its economic value. The wax was found to contain too much water to make good candles (they spluttered uncomfortably when burning); but this defect could doubtless be rectified by proper treatment.
 20. *Lecanium coffeæ*.—Once our principal coffee pest is now quite in the background, having been ousted by the more dominant species *L. viride*. It has transferred its attentions to tea and is sometimes found in force upon individual trees, generally such as are under the shelter of some overhanging rock.
 21. *L. longulum*.—A decided pest of some of our most valuable shade trees. I have found it upon the 'sau' tree (*albizzia*) and very commonly upon grevilleas—often in such numbers as to stunt the plant.
 22. *L. nigrum*.—Another quondam coffee pest, now seldom found upon that plant, but occurring abundantly upon many wild trees and shrubs, and also upon several garden plants, more particularly upon begonias.
 23. *L. tessellatum*.—A widely spread species in Ceylon. It is often very abundant upon the fronds of the 'kitul' palm (*caryota urens*). I noticed it in the Palm House at Kew Gardens upon the same palm and found several of the gardeners engaged in picking off and destroying the scales.
 24. *Triococcus arancarse*.—When I was at the Hakala Gardens some few years ago, several 'Norfolk Island Pines' (*araucaria excelsa*) were badly infested by this species. The presence of the pest was noticeable at some distance by the unsightly black fungus that followed the attack. The trees were greatly disfigured, and I believe ultimately seriously injured.
 25. *Ithobius ventralis*.—Of the 'lady-bird' beetles, this is the species that seems most promising. It feeds principally upon that particular group of scale insects known as the *Lecanidæ*, of which our *Lec. viride* is a prominent member. This bug being a soft-bodied insect it is particularly open to attack from 'lady-bird' beetles.
- I am sorry to note that several of our indigenous "lad-birds" are retiring before the advance of a very pertinacious little ant (*Cremastogaster dohrni*). This insect is particularly fond of the sweet excretion from the bugs and frequents the buggy trees. As they distinctly encourage the bug, they naturally discourage any interference from predaceous insects, and that the discouragement can be most effective, can be readily proved by disturbing one of their nests. The occupants swarm out upon the intruder and give him a very unpleasant reception. These ants build large nests that have the appearance of being composed of masticated brown paper.
26. The Japanese beetle, or rather its larva—is evidently allied to the insect formerly known in Ceylon as "White Grub." Mr. Kœbele was most fortunate in finding such an efficacious remedy as the fungoid disease described on page 83 of this Report.

PROF. ALBERT KOEBELE AND HIS
WORK AS ENTOMOLOGIST IN
HAWAII.

(From the Hawaiian "Planter's Monthly.")

ALAMEDA, California, Dec. 31, 1896.

Sir,—I herewith submit a report of work done since my appointment as Entomologist.—A general account of the conditions of the injurious insects, and the natural enemies introduced from those countries visited. My sincere thanks are due to you for the deep interests taken in the important work, for receiving and liberating the various predaceous and beneficial insects so promptly on their arrival, without such help the results would not have terminated so successfully. We have accomplished what had been desired, namely—the eradication of the worst blight or scale plague that ever appeared in any country. Once more, I consider my duty in the interest of your fair Islands, by any and all means, to prohibit the importation of any soil from all countries, and herewith avoid what in the future could never be remedied,—an everlasting plague of Scarabaeids that would devastate the Islands.

The one species so far introduced from Japan in soil, *Adoretus umbrosus*, F., has partly shown what the beetles may accomplish. Fortunately the larva of the same is not injurious, and it is chiefly in the larva form that these insects do the most damage by devouring the living roots of mostly all plant life. We have records countries where those larva do damage. The May beetle or Cockfaer of Europe has cost the various countries untold fortunes for centuries past. Asia, India, Australia and America suffer likewise from effects of these beetles, all this in countries where the respective insects have their natural enemies in sufficient quantities to keep them in check to a certain extent. If any of the hundreds of species were introduced in the Islands, their effects upon plant life would be most disastrous, with no enemies present, and a continuous warm climate, where we could expect at least four broods of the beetle to one in a temperate clime. I doubt that *Adoretus* has more than one brood per year in Japan, where it is rare, and yet I have bred it in Honolulu from egg to maturity in seven weeks.

But little more can be presented in regard to the introduction of injurious scale insects. There are but very few serious species not yet represented in the Islands from those ports from which plants generally arrive. We can see those and know pretty well how to deal with and where to find their proper enemies. *Aspidiotus fuscus*, Comstock, is found upon very many plants and usually considered one of the worst scales was not yet met with, although it may be present since it is common in Japan and China upon nearly all plants, and must have been brought into Honolulu repeatedly. Even this need not to be feared much, as we have the most effective enemies for the same already present.

Chionopsis Citri, Comstock, is another scale affecting citrus trees, apparently not yet present. We have fungoid diseases established upon the Lecanidæ on the Islands, and hope for the same success with the *Diaspidinae* as well.

The various out worms, the Ponallo; the *Aleurodes* on coffee; *Phociloptera*, likewise attacking this and many other plants, and various enemies still affecting the sugar cane will receive immediate attention by judiciously selecting and introducing predaceous and parasitic insects for the same.—Respectfully,

ALBERT KOEBELE.

Mr. J. MARSDEN,
Commissioner of Agriculture and Forestry.

REPORT OF THE ENTOMOLOGIST OF THE
HAWAIIAN GOVERNMENT

As you are well aware my first and chief work had to be directed against the numerous scale insects at the time infesting and destroying many of the valuable fruit, ornamental and shade trees. Up to

the present time, some sixty species of these have been found on the Islands, and some of them would have made it utterly impossible to raise the citrus and coffee trees successfully. In fact, most of the shrubs and trees at the time were so infested by the then recently introduced and most pernicious coccids ever met with, *Dactylopius vastator*, Mask, that their destruction in the near future seemed imminent had not relief been brought. Without doubt their destructive work would have spread over all the Islands, notwithstanding the most diligent prevention on your part. The scale has not been met with as yet in any of the other Islands, and at present wherever it may appear, its enemies are awaiting it, the chief of which no doubt is the Australian Lady bird, *Chryptolaemus montrouzieri*, Mulsant. The coccid is a native of China where it had been met with in the neighbourhood of Hongkong.

Another numerous scale, and one that had longer been introduced than the previous species, *Dactylopius ceriferus*, Newstead, had always been seen covering the leguminous trees often to such an extent that many of them lost their entire leaves and in some instances even were destroyed entirely by the quantities of Mealy bugs present. This species also is kept in check by the *Chryptolaemus* beetles, which increase to such an extent in the early summer that millions of their larvae can frequently be seen crawling around where the coccids abound. Often this very beneficial insect, for it is always in larval state where they do the most execution, are taken for so-called (blights) and are in consequence destroyed. It should always be borne in mind that the scale insects or blight are generally stationary *i. e.*, fixed to the branches and twigs of plants, very rarely move about, and then only very slow; the *Chryptolaemus* larva on the contrary is quite active, and when full grown is about a quarter of an inch in length, covered above with six rows of contiguous elongated white mealy secreted appendages. It is then that they can be seen in such numbers that often the fences and walls are covered, the trunks and limbs of trees bear patches of the pupae, often several feet in length. The insect was met with in tropical Australia, New Caledonia, Fiji, Ceylon and Southern China, and will apparently live out of doors in the tropics only.

Another *Dactylopius* has occasioned great inconvenience in the cane fields, known as *D. chalcoplariae*, Maskell. Here also the *Chryptolaemus* beetle appeared, and waged war upon the same with the consequence that at present time the pest has also practically disappeared. This scale was met with in Fiji and tropical Australia.

Dactylopius alonidum, Linnaeus, has been present upon most all plants. It is this scale that has marred the coffee industry in the Islands ever since the attempt was made to grow the tree over fifty years since, by its large numbers sitting around and sucking out the sap of the young berries, producing a premature coloring and dropping of the same. It likewise lives upon the roots of coffee and many other trees and plants in the tropics all over the world, whilst in colder countries it is found upon greenhouse plants chiefly. The injury to the various vegetation formerly caused by the foregoing and many other species of *Dactylopius* present on the Islands, is now practically done away with. We have sufficient enemies present for them for all time to come.

Pulvinaria psidii, Maskell, another introduction from the Orient, had spread considerably over the Islands, and caused some anxiety, especially in the coffee districts. I myself must confess that nowhere have I ever seen a landscape so completely blackened by the fungoid growth, caused by the honey exudation of the *Pulvinaria* scale in which this grows, as that of North Kona on my visit in February, 1894. On my recent trip to the same place, all these had changed, and the district, to me, had the appearance of another country, all owing to the presence of the *Chryptolaemus* beetle that devours the eggs of the scale. Since then various

other species of lady birds were sent there, and still more will be sent, all of such that will prey both upon the eggs and mature insects.

The rose apple, *Eugenia malaccensis* was ill found covered by the black fungus. Here another tropical scale, *Lecanium acuminatum*, Signoret, is present in large numbers upon which the *Chryptolaemus* beetle will not feed, yet many other lady birds have been sent that will feed on this and all species of *Lecanium*. The above scales have so far been the most numerous and destructive, yet other forms as well have been on the increase and I can give a short account of some of them only, as many of the species are not yet worked up.

Aspidiotus aurantii, Maskell, is injurious to citrus trees chiefly in temperate zones and may have come upon those trees from any port in California, Australia, China, or Japan. It was found upon recently introduced *Potocarpus* plants from Japan. The climate of Honolulu appears not to be suitable for the same as it was not met with in the tropics as injurious to citrus plants. At Sydney it was found upon *Pereia carolinensis*, *Laurus nobilis*; Brisbane, numerous upon *Jasminum*; at Rockhamden on wild fig tree; Cairns, cultivated figs and Morussp. In Ceylon on Agave (Green); Hong Kong on *Paliurus ramosissimus*; *Litsea sebifera*, *Hedyotis acutangulus*, (very numerous) *Stillingia sebifera*; on *Melia azedarach* at Amoy, Swatow, Hong Kong, Formosa and Honolulu; Japan on *Potocarpus* and *Dumara* like trees, also many other plants. One Chalcid parasite *Aspidaphagus citrinus*, Craw, is preying on the same in China, Japan and California.

Aspidiotus cydonia, Comstock, was found on a garden plant at Pahia, Maui, and upon Ake at Honolulu.

Aspidiotus longispina, Morgan, infests trunks and branches of Orange, Lemon Mango, Kuku tree, Figs, Pride of India, etc., on all the islands and even a common weed at Lihue, Kauai. The scale was found at Tamsui, Formosa, on Orange and upon Fig trees at Hong Kong. A large number of the scales are punctured with holes from where a minute Chalcid parasite has issued that keeps the scales in the check.

Aspidiotus duplex has been repeatedly introduced on *Camellia* from Japan where it also is found upon the tea and other plant it has as yet not become injurious on the Islands.

At Makaweli, Kauai, *Aspidiotus camelliae* and *A. nerii* were found upon imported American apple, pear and peach trees in such numbers that some of the trees had died. A number of other species of *Aspidiotus* were met with in the Island, all of them introduced.

Of *Parlatoria*, *P. zizyphi* is the most numerous upon Citrus and another tree at Honolulu. *P. pergandei* is as yet not so numerous. The first was found at Hong Kong and Canton infesting Citrus trees, and the second upon *Enonymus* at Yokohama and on *Camellia* at Maceo. *Mytilaspis citricola*, Packard, is the scale at present found so numerous upon citrus trees at Honolulu, where it had spread within two years. A number of introduced lady birds are preying on the same, and as far as my observations go, I believe that in time they will effectually keep the same in check. The scale also infests *Croton* and other plants. It is common most everywhere in the world. It is found in the Kona (Hawaii) district but not numerous. *Mytilaspis gloverii*, Packard, has at present only been met with in a citrus tree in Mr. Jordan's yard. The tree had been imported from Japan or China where the coccid is numerous, and with the foregoing one of the most destructive to citrus plants.

Mytilaspis pallida, Green, has been found upon imported Japanese *Potocarpus* plants. *Mytilaspis flava*, Targioni Tozzetti, was met with upon bark of various shade trees at Makaweli, Kauai, and in China upon *Pyrus sinensis* (Hong Kong). *Mytilaspis pomorum*, Bouche, the apple bark louse, was also found on imported American plants.

At Makaweli, Kauai, *Diaspis rosae*, Sandberg, is the common rose scale and is found all over the world. *Diaspis boisduvalii*, Signoret, has been found on imported orchids.

Chinaspis biclavus, Comstock, is found over all the islands on bark of various trees and always badly parasitical. It is not serious in consequence. It may have come from any of the South Sea Islands or Asia. *Chinaspis eugeniae*, Maskell, is a widely distributed species, it occurs in Australia, Ceylon, China, and Japan and lives upon very many plants. The scale has been doing well with Mr. Jordan, upon imported Japanese *Magnolia* and *Eugenia*.

Chionaspis prunicola, Maskell, *Diaspis patelliformis*, Sasaki, *Diaspis amygdali*, Tryon, has been found upon imported Japanese plum trees that had died from the effects of the scale which appears to be very injurious in some temperate zones. It is still present upon Japanese pear tree on same place at Honolulu. In Ceylon it was found on bark of *Aleurites triloba*, at Hong Kong, on *Rhuspa*, Amoy, on peach, on the same tree at Formosa and unknown wild shrub, in Japan always on *Pyrus*, *Prunus* and *Morus*, on *Juglans*, *Elaeagnus*, *Ribes rubrum*, *Salix*, *Sterculia platanifolia*, *Fraxinus*, *Ociza japonica* and many other trees and shrubs. While I anticipate no serious trouble from this coccid in the islands, yet it should not be allowed to get a foothold, and should be stamped out in the beginning.

Erormia camelliae, Comstock, was first noticed upon imported Japanese *Potocarpus*. It is found most anywhere and has been met with in Australia on many plants, in Ceylon on *Mistletoe*, on *Oleander* at Amoy, in Formosa on *Psidium* and *Juniper*, Japan on *Potocarpus macrophylla*, *Sciadopitys verticillata*, *Camellia*, *Euonymus*, etc., on *Alligator pears*, palms, *Camellia*, etc., in Honolulu. *Aspidiophagus citrinus*, Craw, is preying upon the same.

Ceroplastus rubens, Maskell was found but sparingly in the beginning of '94, yet at the present it may be seen anywhere and upon most any tree in Honolulu, although numerous, it is not very injurious compared to other scales. The insect no doubt was introduced with plants from China as it is quite common around Hongkong and there lives chiefly upon the various pine trees. In Ceylon it was found upon *Jambosa vulgaris*. Two species of Chalcid parasites live upon the same in Honolulu, viz: *Tomocera californica*, How, and *Coccophagussp.* A third species that is preying upon *Ceroplastes floridensis*, Comstock, in Japan, has been introduced in some eighty specimens of both sexes.

Both *Ceroplastes ceriferus*, Anderson, and *C. floridensis* have, at innumerable times, been brought in on plants from Japan and China, yet none of these appear to be established.

Lecanium acuminatum, Signoret, is present on many plants in the Islands, yet chiefly upon lime and lemon. It is always badly parasitized in Honolulu by two species of Chalcid flies.

Lecanium filicum, Boisduval; *L. Hemisphaericum*, Targioni Tozzetti; *Lecanium coffea*, Nietner, is found upon very many cultivated and wild plants throughout the islands, and is preyed upon by internal parasites; it is found common all over the world, chiefly so in the tropics.

Lecanium hesperidum, Linnaeus, is but rarely found on the higher altitudes; it comes from the temperate zones.

Lecanium longium Douglas, is one of our commonest species and attacks most any plant on all the islands. It was this species that caused the smutty appearance of the ironwood trees in the park before the introduction of the *Rhizobius* beetle. It is found in the tropics only out of doors.

Lecanium mori, Signoret, is found also upon many plants in the islands, on various ferns, guava, etc.

Lecanium nigrum, Nietner, the commonest of all scale insects in the islands, nearly always can be found upon the Hibiscus hedges, *Croton*, guava, fig trees, etc. It was met with everywhere in the tropics, Fiji, New Caledonia, Queensland, Ceylon, Singapore, Hongkong and Formosa. In Japan it can not live out of doors, and is found only in green houses.

Lecanium oleae, Bernardi, is not found numerous in tropical countries, it is rarely met with in Honolulu. Only in one instance have I seen it numerous upon oleander, on Hawaii.

Lecanium Tessellatum, Signoret, another species found here and there, but not numerous as yet, it is more often attacked by internal parasites.

Pulvinaria, mameae, Maskell, and an unnamed species in Kona, are perhaps the only well established species aside from *P. psidi* mentioned above. It had first been found upon *Mamea Americana*, Linné, during Jan., '94, but since then it was found on many trees in Honolulu, especially mango and fig. No parasite has been observed on the same, yet without doubt the *Chryptolaemus* larvae and those of the numerous species of *Hyperaspis* introduced from California and Japan will destroy its eggs. A fourth species of Pulvinaria was found at Honolulu upon newly introduced *Potocarpus* from Japan, where the insect is rather rare upon many trees, especially the camellia and magnolia.

Planchonina sp., so far but one specimen was found in Honolulu upon *Jacaranda mimosifolia*, *Prosopis dulcis*, *Oleander*, fig trees, etc., and it is preyed upon by an internal Chacid parasite to such an extent that in some instances the scale has disappeared entirely from some trees. Found at Hongkong, China, upon fig tree and badly parasitized. *Bryococcus araucariace*, Maskell, is found on all the Islands upon the various species of *Araucaria*; it comes from Australasia.

Of *Dactylopius* we have a great many species in the Islands but yet they are with a few exceptions, not worked up. It is one of the most easy species to introduce, since many of them when full grown will often leave the plant and secrete themselves most anywhere to deposit their eggs, often on the roots, in any crevice or behind leaves on stem, etc., the most minute examination of plants could not reveal them.

Icerya purshasi, Maskell, is so far the only species present in the Islands. *I. Aegyptiaca*, Douglas, and *I. Sulphurea*, Maskell, are found on many plants around Hong Kong and may be brought in at any time. The two lady birds preying on those species in China viz: *Kodolia fumida*, Muls. and *R. pumila*, Weise, were introduced and no doubt are breeding upon *I. purshasi* which once so numerous, can now only be found after careful search.

The above comprise the principal coccids found in the Islands, very many of them are preyed upon by internal parasites but were brought in with their host. Some of these are doing very beneficial work, often destroying a large percentage of the scales. Only in few instances were scale insects with internal parasites introduced by me, since there is more or less risk in doing so, it was considered the safest way to follow, only to send the numerous predacious insects found preying on the scales and here we have the numerous lady birds, some two hundred species of which had been introduced with more or less success. It seems that those introduced from the tropical countries, or such that are found in similar latitudes to that of the Islands within a few degrees, have succeeded best to establish themselves: especially when the same coccid upon which they fed in their home was at hand, the increase was marvellous.

Aside from the parasites and predacious insects introduced we have established two species of fungoids destructive to all the Lecanidae and these have since spread over most parts of the Islands. A repeated trial with a third *Microcera coccophylla*, that lives upon the expense of the various *Diaspidinae*, has as yet not been so successful. Still I am confident of also establishing this very valuable agent to eradicate the scales. It was met with in New South Wales northward to Cairns, Queensland. It is present in Ceylon, China, Formosa, and even as far north as southern Japan, chiefly upon the various *Aspidiotus* and *Mytilaspis*, coccids that are always abundant where they occur, owing to their hard protective covering, the enemies preying upon the same have not the equal chance as those preying upon other scales.

At the present time, the most pernicious coccids, at least, have practically become harmless and will become still more so with the increase of their various enemies. I anticipate no danger to the

vastly increasing coffee culture by scale insects still present, some of these will yet cause a little trouble to the citrus trees, but I am confident to overcome the same in the near future, as has been done in the past, not with artificial means, but with natural enemies, which if once established, are an everlasting benefit to the country where introduced.

Of the introduced Coccinellidae I will give a short account of some of them. To my knowledge, and that of Rev. Blackburn who studied the insects on the islands some twenty years since, only three species of lady birds were present. Those were *Coccinella abdominalis*, Say, and American insect and no doubt, introduced at a very early date, since it has been known to the oldest residents. It feeds upon *Lecanidas* and *Aphids*, is not a fast breeder and since the introduction of other forms has become much less in number. The other two are small *Scymnus*, *S. ocellatus*, Sharp, and *S. vividus*, Sharp, the last at least, has repeatedly been found breeding upon plant lice. Owing to the large quantities of *Coccinella repanta* on the Islands, none of the California forms that live upon plant lice have been observed as yet, save that one visitor on the dinner table in the club on Nov. 10th, viz: *Coccinella Californica*. Man., introduced three years since, yet we are safe to say, several species will turn up in time, if properly searched for. *Chilocorus bivulvum*, Muls., was brought to the Islands, in 1891, on my trip to Australia and turned over to Mr. A Jaeger, who liberated the same.

Again large quantities were sent to you during Dec., '94, with all other California forms. The insect was found breeding, both in '94 and during the last summer, yet never numerous. This is one of the most numerous native lady birds in California that feed upon various scale insects, and a higher altitude may be suitable for their increase. Sendings of these as all other forms will be made again to the various parts on the other Islands direct. *Hyperaspis* were sent to you in several species, all of these feeding upon the various mealy bugs, (*Dactylopius*), then and still so numerous in Honolulu. You have forwarded one of the beetles to me at Sydney, some ten months later, as breeding in Honolulu. This has been *H. undulate*, Say., and I personally have not met with it since, owing no doubt to the enormous increase of other forms, and in consequence the scarcity of its food.

Large numbers of *Scymnus* were also forwarded to you, and strange to say one of the very rarest California species, *S. debilis*, Lec., that had not been found again ever since being described over forty years ago, was met with in quantities while collecting *Rhizobius* upon *Casuarina*. The little beetle in California breeds upon *Dactylopius*, and very likely on the same in the Islands, *D. Calceolaria*, Maskell, on the sugar cane would be similar to that on grass in California.

Of the Australian forms we certainly have the most beneficial of all the lady birds introduced. Of the *Aphis* feeding species, *Coccinella repanta*, Thunb., has done wonders in destroying all the; various forms of lice on trees, shrubs and plants. It appears usually first up on the orange plant louse it has practically cleaned out the taro louse, and with it has cured the formerly so prevalent disease upon these plants which decayed to a large extent in consequence of the myriads of plant lice present; and recently it has shown its ability upon the newly appeared louse in the cane fields at Kauai, Oahu and Maui. It has spread within one year, after being distributed by you, over all parts of the Islands, and was met with both on Hawaii and Maui as high up as timber will grow. How unfortunate, that upon such beneficial friends we should find a parasite destroying the same to a large extent, yet such is the fact. Everywhere the beetles may be found, apparently at rest on the leaves, yet under it and between its legs a small yellowish silken cocoon is found, from which in due time hatches a small black hycenopterous parasite, *Centistes*, Americana, Riley, an insect found all over the world preying on aphid feeding lady birds. How long the parasite has been present on the Islands is hard to say. Undoubtedly it had been breeding upon *Coccinella Abdominalis* many

years. It had been found upon the same by Messrs. Miller and Wait at Kona before the introduction of other Coccinellids by me. *Leis conformis*, Boisd. had been observed breeding upon the orange Aphis early in 1894. Another very valuable lady bird that feeds upon the various Aphids, and one that had always been found in small numbers only in Australia is *Platynomus lividigaster*, Mulsant. It was met with in that country from New South Wales up to Cairns, Queensland, and chiefly upon the orange Aphis. It was also noticed that a large percentage of their larvae were destroyed by a parasite, and owing to this fact the comparative scarcity may be accounted for. On the other hand, there is no such parasite as yet known in the Islands, the beetle was never yet found destroyed by the Centistes fly and in consequence may even prove of more value in time than the *Coccinella rapanta*. Its dusky larva is unlike those of the *Coccinella* proper; it is covered all over with long spines for protection. The rather small black beetle is nearly round and has the sides of thorax bright sulphur yellow. It is a most active creature.

Of *Orcus*, *O. Chalybeus*, Boisd. has increased most upon the various Diaspidinae chiefly, yet it will feed up on most any scale as well as Aphids. The *Chryptolaemus montrouzieri*, Mulsant, is in my opinion the most valuable lady bird introduced into the Islands. It is always found upon any plant infested with Mealy bugs. It relentlessly follows up that destructive *Pulvinaria* and devours its eggs. It likewise devours *Eriococcus araucariae*, Maskell, infesting the various *Araucaria*. You distributed the same during 1894, and on my recent inspection it was met with everywhere on all the Islands upon its fast disappearing food; around the Volcano, upon the various forest tree, and shrubs it was very numerous; from thence down Pahala over the lava flows it was numerous upon the scanty bushes growing. In Kona it was met with up to an altitude of 6,000 feet, and here was simply swarming upon *Myoporum sandwicense*, Gray, infested with *Lecanium fillicum*, Boisdual, its larva feeding upon the *Dactylopius* present. On Maui it was found upwards to the timber line and is very likely even higher. That far famed *Vedalia cardinalis*, Mulsant, did good work in Honolulu upon the one scale, *Icerya purchasii*, Maskell. The *Chryptolaemus* beetle did equally well upon about a dozen species of coccids. Many other enemies were introduced for the *Icerya* scale, and one of them at least, *Novius Koebeleii*, is at present abundant.

Of *Rhizobius* a large number of species were introduced, and *R. ventralis*, Erichson, that feeds upon the various *Lecanidae*, has become the most abundant. It will feed upon *Pulvinaria* as well and can at any time be found upon *Araucaria* trees, preying upon *Eriococcus*; owing to its valuable work the numerous species of black scales are disappearing. At the Kapiolani Park the *Casuarina*, formerly a complete black mass, owing to the numerous *Lecanium*, *longulum*, Douglas, have entirely recovered from the blighty appearance, and both the beetles and larvae could be found in any numbers during summer. Of the smaller Australian beetles, *Cyrene nigellum*, Blackburn, has perhaps increased most, and it was met with everywhere in Honolulu.

With the Ceylon Coccinellids nothing could be done, the distance is too great and all arrived at Honolulu dead. One of these, and certainly the most valuable found there, *Chilochorus circumdatus*, Gyllh., was later sent over from China. This insect had been recorded from Ceylon, India, and Sumatra, and consequently its occurrence around Hong Kong could be expected. During three months, Oct. to Dec., '95, a careful search had been made in the neighbourhood of Hong Kong, and of the insects introduced many are breeding in the Island.

Synon che grandis, Thunberg, is the largest known lady bird that feeds upon *Oregma bambusae*, Buckton, infesting the various *Bambus* plants in the Maui Archipelago, Ceylon, China and the southern Japan. A fresh specimen of these was found upon orange Aphids in Honolulu on May 6, 1896, and may have bred here. *Verania discolor*, Fabr., found near Hong

Kong and Swatow was again met with in Honolulu eleven months later; it feeds upon Aphids. *Coelophora pupillata*, Swartz, found common near Hong Kong upon *Celtis sinensis*, infested with *Psylla*, was met with all summer upon Aphid at Honolulu.

Coelophora hiplagiata, Swartz, collected and sent from Hong Kong, has been noticed in Honolulu for several months after my return. *Chilomenes quatriplabiata*, Swartz, had been observed breeding upon plant lice, and *Dactylopius* and will prove a valuable addition. *Cryptogonus orbiculatus* Gyllh., is a very common little lady bird. It was found numerous upon orange, etc., at Atami, Japan, it was breeding by the thousands upon *Mimosa pudica*, L., infested with *Dactylopius adonidum*, Linn.—the common Mealy bug—at Coo-loong, China, and in Formosa again, it was numerous upon the tea plants that were infested with *Chionaspis theae*. This will be another valuable help in destroying the various Mealy bugs. The beetle was found very numerous during Nov. at Honolulu.

Platynaspis nigra, Weise, has been sent both from Japan and China, in the former country it was always one of the commonest lady birds upon orange infested with *Diaspidinae*. At Yokohama it was bred in numbers from a small powdery white larva on trunk of *Styrax japonica* S. and Z. It was always in numbers upon camellia hedges infested with various scales; found common in China upon orange and feeding upon *Aspidiotus Diaspis* and *Mytilaspis*; also at Formosa numerous upon *Chionaspis theae*. In Honolulu likewise, the little beetle lives upon the hardest scale insects such as *Aspidiotus aurantii*, Maskell *A. longispina*, Morgan, and *Mytilaspis citricola*, Packard.

Sticholotus punctatus, Crotch, was found in Japan and China, in Honolulu during the summer always upon *Eriococcus araucariae*, Comstock, upon *Aleurodes* sp., infesting *Jasmin*, and upon many other plants. While searching for Coccinellidae to be forwarded to the other Islands, in the beginning of November, the little beetles were swarming, so to speak, in the Government Nursery upon most the tree trunks, on fences, etc., searching for a hiding place to winter in. The species of lady birds enumerated above are no means all that have established themselves on Oahu. Only in some four gardens in the city where they collected, and a thorough search for them no doubt will reveal many other forms; some may even breed in the forest on the mountain where he have not looked for them.

Of the other introduced predaceous and parasite insects, it appears that some *Syrphid* and *Chrysopa* flies are established. *Chalcis obscurata*, Walker, is making war in earnest upon the *Pyralid* larva destructive to the coconut leaves, *hanani*, sugar cane, etc. Finding such an abundance of *Lepidopterous* larvae it also preys upon those of *Tortricidae* congenial climate, and no parasite present to prey on its own larva, it is no wonder that within one year this parasite has increased to such an extent that on one occasion, at the beginning of November in Mr. Jaeger's garden, they were seen flying around the trunk of *Pritchardia filifera*, which has still all the old leaves remaining on the stems, in a perfect swarm. It is in such places that they hibernate for a short time. The insect was found in numbers upon orange trees in the early spring at Japan. In China during November and December they could be found by the dozens sitting amongst the leaves of *Pandanus*. This Chalcid fly was met with all over the Island of Oahu during the summer, flying actively around the shrubs and trees in search of their prey. It was sent to Kauai and Hawaii. A second introduced parasite was found to prey upon the *Pyralid* larva on coconut leaves, a species of *Proctotrupid*, not yet identified, it was sent from Japan with many other forms; this also was introduced on Kauai.

In addition to the numerous predaceous and parasitic insects, it was also found advisable to introduce Rats, Toads and Frogs. So far the results of the introduced California Bats, of which over six hundred reached the Islands living, has not been very encouraging, since little is seen of them in Honolulu.

Several trials with Japanese bats resulted in a failure. On the other hand toads from California and Japan are breeding and the four species of Japanese frogs no doubt as well. The benefit to the Islands through the introduction of these Batrachians will be considerable. Since all of them live chiefly on insect life, they will have sufficient food for a long time to come, on the numerous Japanese beetles (*Adoretus umbrosus*, var. *tenuimaculatus*, Waterh.), on the cane borer (*Sphenophorus obscurus*), and the numerous cut worm larvae.

A great many of injurious insects are yet present on the Islands, and they will be dealt with entirely by introducing natural enemies for the same. Artificial remedies even if effective for a short time are too expensive, and if possible I will not recommend such. We cannot use effectively washes or hydrocyanic acid gas, as is done in America, without injury to the tropical plants. I have taken the work upon me to do the best for the Islands without further expense, and I will not recommend nor even approve of them. (We yet will have to deal with the various cut worms and other noctuid larvae that are a serious drawback to the growing of garden produce.) *Agrotis ypsilon*, Rott., a cosmopolitan insect, is probably one of the commonest and most injurious, it is found on the sea shores and up to the highest mountain peaks. A saucia, Hbn, another moth found everywhere, was also observed to attack garden vegetables on the higher elevations and also a number of other species of *Agrotis* equally injurious.

The American army worm, *lecania unipuncta*, Haw, is very numerous. It feeds upon grasses, and consequently equally well upon the sugar cane. At Olaa a Noctuid larva was seen swarming upon and destroying the various weeds amongst the coffee plants, not feeding upon these however. The larva of *Plusia verticillata*, is doing more or less damage to the young coffee plants. The most numerous of all however is the Pelua, *Laphygma frugiperda*, Hbn, occasionally found covering grass land for miles. Then there are large numbers of Tortricids, Pyralids and Tineids present. All the introduced species are injurious in more or less extent according upon what they feed.

Upon all the many introduced species of Moths there are exceedingly few introduced parasites to be found, the indigenous forms living upon native moths are hardly ever met below an elevation of 1,500 feet. The most valuable parasites of Noctuid larvae are the *Tachina* flies, of which but one native species exists on higher elevations.

Of *Migrogaster*, none have been observed upon Noctuid nor Sphingid larva on the Islands. Many injurious moths have found their way to the Islands, yet save a very few hymenopterous parasites, we may say they practically enjoy an almost entire immunity from such.

A small white fly, a species of *Aleurodes*, is causing some anxiety in Olaa district. They have increased enormously upon the coffee trees. Many insects preying upon the same were recently sent there, and others will follow in succession, as well as internal parasites, and I am confident with these they will speedily disappear. At the same place Slugs are also destructive, and a trial will be made to introduce such beetles as are known to live upon the same.

THE JAPANESE BEETLE.—This beetle, *Adoretus umbrosus*, Var.; *tenuimaculatus*, Waterh., has been probably introduced from that country, and more than likely in the soil coming with the numerous plants from there. I met with the insects quite frequently during summer around Yokohama especially while collecting in the forests, where they fell in my umbrella while beating for the various coccinellidae on oak, alder and many other forest trees upon which they feed at night. Not in one instance did I see a specimen in a garden. It is the various species of *Cetonia* that come to and eat the flowers in gardens, and principally the roses. Repeated search was also made for the larva of these beetles in gardens, yet it is always that of other and larger species that are met with in such places, and the

injury caused by them by eating the roots of the various garden plants is very annoying. It was observed at one place that the most of the violets were practically eaten by these larvae under ground. Mr. Alfred Unger of Yokohama, related to me an instance of the value of the mole as an enemy for the Scarabaeid larva which is worthy to record. A gentleman at that place, in building a lawn for a cricket ground, had a brick wall surrounding this to a depth of several feet to prevent the moles from injuring the lawn. All went well for a few months, at the end of which the grass began to get yellow and die off. All efforts with manure and water were useless, and he continuously found larvae of Scarabaeids that had come to the surface to die. Nothing could be found to remedy the evil until Mr. Unger advised the gentleman to tear away the wall and give the moles access to the larvae, which was done, and to the pleasure of the party, his lawn soon recovered.

The beetle at the present time is found all over Oahu, on Maui and Kauai and it will be but a question of time when they will appear on Hawaii, if they are not already present. In going over to Kauai, the insect was found flying around the lamp on the steamer, and also off Maui, on the way to Hilo, one of the insects was found in similar condition. The most trouble will be experienced by the same in the drier localities, whilst in places like Olaa, the fungoid disease destructive to the same will flourish upon and destroy most of them.

ANNUAL BROODS.—In Japan, where the temperature will probably allow the larvae but six months active life, it may be that there it has but a single annual brood, and with the many enemies present it is no wonder that the beetle in consequence can be called rare. I have had the larvae barely out of eggs in Honolulu, and yet in three weeks later they were full grown upon the decayed manure—not in general use in Japan—where they doubtless fed upon decayed vegetable matter, as they also do on the Islands. The elongate small white eggs hatch in about seven to ten days, and the pupae gives forth the mature insect in from ten to fourteen days. Thus it will be seen that the whole transformation takes from six to seven weeks in summer at Honolulu.

FOOD PLANTS.—These are too many to be enumerated. After the roses were gone the beetles paid their attention to various other bushes and trees in Honolulu and but few remained entirely free from their attacks. The orange was more or less attacked, and so had been the Arabian coffee tree, yet the Liberian coffee tree in some instances was practically defoliated, as were peach trees. The taro and cane leaves are also relished; and like the guava, alligator pear, pomegranate, Java plum; the grape vines are defoliated, and so is the umbrella tree (*Terminalia catalpa*), various palms, especially *Areca* and *Phoenix*, *Cycas*; many of the garden plants, as the Mexican vine, sunflower, and even violets, suffer from their enormous appetite. Many more plants could be mentioned, but it would be far easier to give a list of such not attacked by them. The same could be said of their work in the forests; here also some of the trees had the appearance as if fire had gone through them.

ENEMIES.—As the beetle is a night-flying insect, only becoming active after the few insect-feeding birds have gone to rest, and as there are no moles present, not even a single Carabid beetle to feed upon the larvae, these can breed in hundreds. The minah bird no doubt devours all the beetles that he can get, yet we never have observed it to search for the same as does the house sparrow. Almost every crevice was examined around houses, walls, etc., and the rough bark of trees likewise. Here the sparrows could be seen climbing up and down the bark nearly as well as a woodpecker, searching for these beetles for its offspring.

Sarcophaga flies were repeatedly bred from jars containing these beetles, and on an old fern stump, hollow within, where the beetles secreted themselves, the newly hatched flies were almost daily observed sitting on the outside. It is a well known fact that these

flies are not parasitic, strictly speaking, and the young maggots, are likely left upon the dead beetles only.

During April last, upon an old root with ferns growing on same, hanging suspended, on the hotel veranda, I found successively three dead beetles, covered by a greenish gray fungoid. The respective root had been brought down from the mountains previous. From out of them the spores were taken and brought in contact with twenty healthy individuals in a glass jar kept slightly damp with Sphagnum moss. They were daily given fresh food, as during all the subsequent experiments. To my astonishment and delight, thirty hours later, one of the beetles was seen dead, with its legs outstretched, and on the various joints the white fungoid growth made its appearance. In two days more the grayish green fruit was present. For weeks these experiments were kept up, always with good results. The fungoid was most successfully raised upon sterilized black bread; less so on white bread, potato with glycerine, sweet potatoes, gelatine with Agar-Agar, banana and fruit juices. Later on the beetles were placed in large tight wooden boxes, the bottom of which was covered with about one inch of slightly damp soil; a few handfuls of dead beetles showing spores were placed on top of this; fresh and slightly damp food was given, and the healthy individuals placed within. Thus we infected quarts of diseased beetles that were distributed all over the Island, and many parties again raised their own seed for distribution. Numerous eggs, placed in infected soil chiefly, hatched; yet all the minute larvae became affected at once after issuing. A few remained unhatched and the larvae were found dead within, yet to all appearances not affected. Larvae dusted with the spores, as a rule begin to die in about five days, become blown and hard, sometimes with a reddish tinge; soon the fungus growth shows on the outside until the larvae appears all white. In a couple of days later the fruit appears, and again the larva slightly shrinks and is covered by the millions of greenish gray fruits or spores. On May 9th a lot of larvae were dug up in a garden, dusted with the spores and replaced. On examining the ground again, May 16th, some were found dead and hard; upon those the spores were ripe two days later. Pupae dusted with spores never hatches, and always produces the fungoid disease.

The virulence of the same upon the beetles was shown already, on August 4th, at Spreckles' garden, under one of the badly eaten Terminalia catalpa trees, the dead beetles could be counted by the hundreds; even on the partly devoured leaves specimens could be seen with stiff, outstretched legs. Likewise at the Government nursery, large numbers of them were lying on the ground.

Both the larva and mature insects of the cane borer are affected by the disease. Later in the season, in a garden where experiments had been carried on, not only did I hardly find any more living larvae of Adoretus, but those of the Aphodius as well were destroyed.

Tineid larvae were found destroyed by the same, and also nice specimens of Nictuids covered with spores were preserved. The large Cerambycid larvae (Aegosoma reflexum) so destructive to sugar cane at Spreckelsville was likewise destroyed by this fungoid. Roaches are as well subject to its virulent effects.

There is little doubt in my mind that in damp localities at least the beetles will have little chance to become very numerous, but how effective the disease will be in dry localities and Honolulu, the next summer will show. The spores have been sent to Washington and Brisbane, Queensland, for experiments at those localities.

A small green Tineid larva appears upon the leaves of sweet potatoes, within which it mines, causing the leaves to turn brown and dry up, and in consequence the plants die off; this is the "Ponallo" of the natives, often destroying the entire plants in whole districts, and bringing great suffering among the poorer classes. The larva likewise lives upon the various other Convolvulus.

The insect was seen at work in Olau, where in about a week's time the whole field of sweet potatoes had turned brown, not a single parasite or predaceous

insect was noticed among the myriads of minute larvae that pupate anywhere on the outside of the leaves to a naked Chrysalid.

This and the somewhat allied *Plutella cruciferarum* living upon the various Cruciferous plants need immediate attention, and hopes are entertained that with the introduction of proper parasites they will become less to such an extent as hardly to be noticed.

PROWLING ROUND.

(By a Peripatetic Contributor.)

I was anxious to see

THE NEW CACAO PEST, of which I had heard so much, but little was visible. The trees looked robust and vigorous, but there were signs higher up that the enemy was at work, though less than I should have expected. There was a sprinkling of crop through the trees, and an appearance of blossom about; but I am told that it is later in the year when most of the damage through the pest is made manifest.

We passed a

FINE NEW FACTORY,

a little way out of Wattagama, erected by Mr. Charles Gibbon, but saw no good tea about until we got higher up. There was evidence all round of

NATIVE INDUSTRY,

in cleared-up patches for tea, some poor enough to warrant disappointment ere long, while other bits looked well enough.

"RAXAWA,"

where the tea was vigorous, and the huge stacks of firewood around the factory, were eloquent of much tea to be made. There was the other side too, of a district denuded of its sylvan beauty along the road to Hatale—which road by the way was in anything but good order—the wide and varied view was charming, but the red patches of new clearings did not improve the outlook. We passed strings of carts loaded up with tea, of well-known marks and there were lots of coolies on the road. Turning up to Kelebokka, there was visible below like a white ribbon through green—the road to John's Hill and Knuckles. At the former place in the days gone by—Padré Burnet used to stay, when he was the itinerary clergyman of the planting districts.—These were the days after the "Knuckles Bricks," when the men had a ready pen and were keen on an argument. What theological discussions and doctrinal tussles there were in the Padre's bungalow, for he was a real "argle-bargle Scot" himself, and no gauge of battle was ever thrown down there, that remained neglected. Ah! these men of the past! are we never to see their like again? Is sport to be the one eternal threadbare theme that intellect is to be wasted on?

BRITISH NORTH BORNEO.

The British North Borneo Government has approved of their officials taking up land for coffee planting, and five of the officials are so satisfied of its being a success that they are taking advantage of the privilege. The enclosed para. may interest your readers. Some very important concessions have lately been made in British North Borneo for the working of petroleum, oil, timber and gold, among which we may mention one to the Bombay and Borneo Trading, Co. for the working of petroleum oil in the Northern part of British North Borneo where petroleum oil exists. This Company have already acquired a

very valuable oil concession in Sumatra, which they are now developing, and the success attending their operations in Sumatra has led to their acquiring a like concession in British North Borneo.

THE TOMATO.

The tomato is rich in possibilities in the hands of a skillful cook. It can enter into and give tone to endless soups; it can be made into purees and sauces and stews; it can be eaten *au gratin*, with macaroni or vermicelli, and *en salade*. There is no reason why it should not be seen more often on our breakfast tables. Carefully grilled and placed on slices of grilled fat bacon, it makes a delicious dish. Then again, we can stew it, place it at the bottom of a dish, and gently deposit thereon poached eggs; or we may vary this by placing scrambled eggs round a pyramid of stewed tomatoes. *Farcie* they can be introduced at breakfast, lunch or dinner; and, as a writer justly points out, "*farcie* tomatoes may not easily be surpassed. Upon your whim or choice it will depend whether you stuff them or cut them in half for so ineffable a purpose. And upon your whim likewise depends the special forcemeat used. Chopped mushrooms, parsley and shallot, seasoned with discretion, leave little to ask for. Prepare, instead, sausage meat, garlic, parsley, tarragon and chives, and the tomatoes so stuffed you may without pedantry call a *la Grimod de la Reymere*. But whatever you call them, count upon happiness in the eating."—*Epicure*.

NORTH BORNEO AND MR. HENRY WALKER.

We refer to another page for such particulars of the attractions now offering in North Borneo to planters and capitalists as may well make the men envious, who have paid sweetly for their lands in this colony and in other less liberal countries. We have been surprised to learn how accessible North Borneo and Sandakan its capital are being made by Holt's steamers—a regular and numerous coasting line—apart from Holt's ocean-going fleet. The proximity to Labuan which is a busy calling-port for the Far East generally, is also a great advantage. We have no doubt that Mr. Walker will have a good many interviewers from among our younger planters, while in Kandy, and that a strengthening of "New Ceylon" with a fresh reinforcement of men of the right stamp may be the result, is decidedly, what we should wish to see. Mr. Walker himself is a man in a thousand, and any pioneer can feel safe with him; while few men have now had so much experience of North Borneo added to a long spell in Ceylon.

INDIAN PAENTS.

Applications in respect of the undermentioned inventions have been filed, under the provisions of the Inventions and Designs Act of 1888, during the week ending 1st May 1897:—

Improved Paddy-husking and Rice-clearing Machine.—No. 166 of 1897.—Johwar Chandra Majumdar, son of the late Haranatha Majumdar, talukdar of village Aghaid, in the district of Dacca, for an improved paddy-husking and rice-clearing machine.

No. 187 of 1897.—Amended application.—See No. 144 of 1897.

Improvements in Machines for Separating and Cleaning the Fibres of Plants of every Description.—No. 381 of 1896.—Samuel Benjamin Allison, gentleman, of New Orleans, Louisiana, one of the United States of America, at present of Guatemala, Central

America, for improvements in machines for separating and clearing the fibres of plants of every description. (Specification filed 22nd April, 1897.)

Improvements in the Methods, Machinery and Appliances used for Withering or Dessicating Tea Leaf.—No. 267 of 1890.—Charles Arthur Burton, manager, Lukwah Tea Co., Upper Assam, for improvements in the methods, machinery and appliances used for withering or dessicating tea leaf. (From 12th May 1897 to 12th May 1898).—*Indian and Eastern Engineer*, May 15.

THE TRAVANCORE TEA ESTATES COMPANY.

(From the Prospectus.)

The capital of the Company is £15,000, divided into 75,000 six per cent. cumulative preference shares of £1 each, and 75,000 ordinary shares of £1 each; but the present issue will consist of only 35,000 preference shares and 35,000 ordinary shares, of which 10,000 preference shares and 14,000 ordinary shares will be issued fully paid to the vendors as part payment of the purchase price. The Directors of the Company are Messrs. H. K. Rutherford, D. Reid, G. A. Talbot, H. Tod, and W. Mackenzie, while the agents are the Ceylon Tea Plantations Company, and the Secretary, Sir William Johnston, Bart. The Company is formed primarily for the purpose of acquiring, working and developing tea and other estates in Southern India, and it is intended with the present issue of capital to purchase and work the following estates as from 1st July, 1896:—Bon Ami estate, Mount estate, Munjamally estate, and Kolie Kanum estate, all situate in the Peermaad District of Travancore, Southern India, at elevations ranging from 2,500 to 3,900 feet. The approximate acreage of each estate is as follows:—

	Tea in Bearing.	Tea not in Bearing.	Tea to be planted 1897.	Jungle Grass.	Total.
Bon Ami	509	98	—	202	809
Mount	135	—	—	15	202
Munjamally	—	—	400	160	560
Kolie Kanum	—	202	300	298	800
Totals	644	300	700	675	2371

The estates have been inspected, reported on, and valued by Mr. H. V. Masefield, the Manager of the Ceylon Tea Plantations Company, Limited, who recommends their purchase.

The prices per acre at which the planted and unplanted lands of Bon Ami, Mount Munjamally and Kolie Kanum are to be transferred to the Company have been agreed, and it is expected when the various acreages are ascertained that the sale price will amount to £48,000 more or less, payable as to £20,000 in fully paid shares of the Company, and the balance in cash. Taking the reserve lands at a value of £3 per acre, the price being paid by the Company to the Vendors for the planted area of the last mentioned properties is equivalent to about £39 per acre.

THE GREAT WESTERN TEA COMPANY OF CEYLON, LTD.

MANURING: ARTIFICIAL AND BULK.

Mr. RYAN said that if he was not taking up the time of the Directors he would ask a question or two about manuring. He found that it was stated in the Report that practically 2½ per cent had been spent in manuring. He would like to know what the total acreage manured was.

Mr. BOIS:—187.

Mr. RYAN said that he kept a dairy and cattle, and he was of opinion that cattle manure on paper did not pay. It was very difficult to make it pay on paper.

Mr. BOIS said it was well if they had not a cattle

establishment, not to get one, but if they had one, keep it by all means.

Mr. RYAN said he supposed that bulk manure paid, but it would not compare favourably on paper with artificial manure. Artificial manure showed better results on paper. He was sorry to say his cattle manures failed to give the lasting power which was supposed to be given by cattle bulk. He had not found cattle manure would keep the yield for 4 years. He found artificial keep for 5 years. That was his individual experience. He noticed that 187 acres had been manured. It was practically only about 20 per cent. Was it not advisable to increase that acreage. They might manure 25 per cent. There could be no better investment, especially with land as old as that.

Mr. MACKIE said they had to go about in a quiet way.

Mr. RYAN thought that instead of decreasing they should increase manuring.

Mr. BOIS said they might increase their yield very materially, and they might increase their prospects but the benefit they derived was nil. In extreme cases of manuring an increase of about 25 per cent would be given.

Mr. RYAN said that at the same time that other people were manuring they must also manure. He would advise to give 25 per cent manuring. He certainly thought in the interests of the Company manuring should not in any way be diminished, and if possible manuring should be increased.

THE CEYLON AND INDIAN PLANTERS ASSOCIATION, LIMITED.

This Company with the initial capital of £120,000, divided into cumulative six per cent preference shares of £10 each and 8,000 ordinary shares of £10 each, has been registered in London; and the Company has purchased the estates in Ceylon called Laxapana, Maha Elliya and Kandaloya. The two former estates have been purchased for £65,000 sterling and the latter for £16,000. Laxapana in Maskeliya contains 864 acres of which 690 are in cultivation, 680 with tea and 10 with cardamoms. Maha Elliya in Dimbula contains 305 acres of which 265 are planted—all in tea; while Kandaloya in Yakkessa consists of 1,006 acres of which 535 are cultivated—530 with tea and 5 with cardamoms.

The Ceylon Agents are to be Messrs. Skrine & Co. with Mr. George Greig of Laxapana as Manager.

CEYLON TEA PLANTATIONS CO., LTD. AND COCONUT PROPERTY.

At the annual general meeting of this Company the other day, after Mr. Talbot's speech, the CHAIRMAN, replying to Mr. ADAMS, said:—

With regard to the first year's profit on the coconut estates, property just taken over from natives was always in rather a bad state, and therefore the initial expenditure was much greater than it would be in the future. The profit earned was about £3 10s per acre, which the directors considered fairly good, but they hoped at the present price of the product to work it up to about £5 per acre. It would be several years before the 1,476 acres came into bearing, but every year there would be a few acres coming in. They were now erecting a mill at Mawatte, by which they expected to add to their profits.

THE ACME TEA CHEST COMPANY, (LIMITED),

with a capital of £150,000, has its prospectus advertised in the London papers. The Directorate is a strong one:—

James T. Tullis, Esq., J.P., St. Ann's Leather Works, Glasgow, Chairman; John Bennie, Esq., Hydraulic Engineer, Glasgow; James Couper, Jun., Esq., J.P., City Glasgow Works, Glasgow; Robert Hart, Esq., Tea Planter, Sylhet, India, and 45, Leadenhall Street, London; Thomas Henderson, Esq., of Walter Duncan & Co., East India Merchants, Glasgow; Arthur Mechau, Esq., Neptune Iron Works, Cranstonhill, Glasgow; William Walker, Esq., of James Finlay & Co., East India Merchants, Glasgow.

We read that,—

The Acme Tea Chest Company, Limited, has been formed to acquire, as at 17th March, 1897, the business of manufacturing and selling Steel Tea Chests hitherto carried on by the Acme Package Company, Limited, together with the works, plant, machinery, patent rights, contracts, and whole other assets of that Company. The business of the Vendor Company since its formation in 1894 has developed to a remarkable extent and is still rapidly increasing. The Company recently acquired in fee extensive and very suitable works, with convenient railway connections at Polmadie, Glasgow, which previously formed the Glasgow Steel Works. These works having been reconstructed and equipped with special and valuable machinery are thoroughly adapted to their purposes, and are equal to an output of from 20,000 to 24,000 chests per week.

To make their own sheets is the great object of the new Company, and we read:—

The Chests are made of lead-coated sheet steel under hydraulic pressure, and they consist of (1) a sheet which forms the four sides, with panels and corrugations which ensure both strength and rigidity; (2) an ingenious "slip-joint" for fastening and clamping; (3) a top and a bottom; and (4) a top band and a bottom band—in all six pieces, to which there are added only six screw-nails, three for securing each of the top and bottom bands respectively. When it is stated that a pressure of 220 tons is required to produce the panels and corrugations on each sheet for an Acme Chest, it will be understood that only the best and softest steel will stand such a test, but, having stood it, the strains and even the accidents to which it may be subjected when filled with tea are as nothing.

(1) The Chests dispense with the employment of costly lead-leaf.

(2) They can be stored in small space ready for immediate use, and are rapidly put together by Coolie labour without special appliances.

(3) They ensure even tares (a most important technical point); and thus minimise warehouse charges.

(4) They may be opened or closed in two minutes (but are easily sealed against pilferage) and so facilitate Customs' examination while avoiding the expense of co-operation.

(5) They prevent loss of tea in transit and preserve its fragrance for a much greater length of time than wooden chests.

(6) Steel being so much thinner, they hold more than wood chests of the same outside size and therefore effect a large saving in freight; being lighter, they also save in inland carriage.

(7) They are preferred by retailers on account of their neat and attractive appearance, and because the empties have a high return value, or may be used again for tea and other merchandise,

Then as to profits:—

The Vendor Company's financial year closes and the season ends on 30th June (the Company's first season having, however, for bookkeeping purposes been closed on 31st May). For season ending 31st May, 1895 (being the first in the existence of the Vendor Company), on sales, amounting to £14,139 2s. 9d., a profit of £1,102 5s. 1d. was obtained. For season ending 30th June, 1896, on sales amounting

to £26,592 14s 10d., a profit of £3,425 16s. 10d. was reached. For season ending 30th June, 1897, orders have already been obtained to the amount of £42,000, from which, according to previous experience, a profit of £8,200 should be made. For season ending 30th June, 1898, it is confidently expected that the total sales will considerably exceed this figure; but assuming that no increase upon sales is attained, and that the saving before referred to arising from the Company manufacturing its own sheets, viz., £4,000, is effected with sufficient expedition to make itself apparent next year, the total profit would, at the same rate as in the previous year, amount to £12,200, sufficient to pay 10 per cent. on the ordinary shares after making provision for the dividend of 6 per cent. on the preference shares. This is believed to be a moderate estimate based on past and present working, but if the business continues to prosper as it has done, and is doing, these figures may be largely exceeded.

Finally,—

The purchase price has been fixed at the sum of £112,500, payable as to £25,000 in Ordinary fully-paid shares, as to £25,000 in 6 per cent. Cumulative Preference fully-paid shares (being the largest portion allowed by the Rules of the Stock Exchange), and the balance of £62,500 in cash.

Mr. P. Stuart-Brown, F.C.S., continues to be Manager.

means, and then by good cart roads and cart service right down to Poonagalla station. This will be a great boon, as the great difficulty all over the Island now is that of Coolie labour. The Coolie can now choose where he likes to go; he can get a good capitation grant, and have his debts paid by any estate. The work which he detests above all other labour is that of carrying produce on his head. If we can get our produce carried down by wire shoots to the factory, and from there by cart, we shall have less difficulty with our Coolie labour than in the past. On the whole, we can congratulate ourselves on the first year's working. We have fairly earned 10 per cent. dividend, and we are paying 6 per cent., and take the unusual proceeding of paying the whole of our preliminary expenses in the first year, and we carry £362 to next year's account. These figures show, I think, a very satisfactory result on the first year's working. Mr. Rettie, the manager of the Spring Valley Estate, and the original valuer of our estate, and whose brother is manager of the celebrated Ouvah Coffee Company, the largest estate in the Island, reports to us from time to time as to the general condition of the estate. He has been here this morning. His reports are very favourable and very hopeful for the future. I don't think that I need say more but I shall be happy to answer any questions which may be put to me. I move that the report and accounts as presented to the shareholders be received and adopted.

Mr. G. G. ANDERSON seconded the motion, which was carried unanimously.

The CHAIRMAN then moved and Mr. ANDERSON seconded that a final dividend of 3 per cent. free of income tax, making in all 6 per cent. for the year, be declared, payable forthwith.—Carried unanimously.

Mr. ANDERSON proposed and Mr. L. F. DAVIES seconded that Sir George Pilkington be re-elected a director.—Carried.

The auditor Messrs. Cape & Dalgleish, were re-appointed, on the motion of Mr. C. J. SCOTT, seconded by Mr. A. LESLIE.

The CHAIRMAN proposed a vote of thanks to the staff in Ceylon and London for their efficient working of the company's property and business. He said that as an almost annual visitor to the Island he could say that they had an extremely efficient manager—one of the most experienced, shrewdest, and hard-working men in that capacity he had ever met with. His conduct in the affairs of the company was very satisfactory. He had also a very good European assistant under him. The London staff also had shown an amount of interest in the work of the company that was beyond all praise.

Mr. J. VICARY seconded the motion, which was carried.

Mr. DONALD ANDERSON proposed, and Mr. C. J. SCOTT seconded, and it was carried, that a vote of thanks be given to the Chairman for his able conduct in the chair, and to the directors for their careful guidance of the company's business.

The CHAIRMAN, in responding, invited any of the shareholders, when on a holiday, to visit the estates. He observed that formerly the British tourist went to the Riviera, now they go to Cairo, and soon they will go to Colombo. If any of the shareholders would take that journey, he was sure that the pleasure that they would derive from it would amply recompense them.—The proceedings then terminated.—*Investors' Guardian*, May 1.

THE TRAVANCORE TEA ESTATES COMPANY.

POONAGALLA VALLEY (CEYLON) CO., LTD.

The first annual ordinary meeting of this company was held at the office of the company, 16, Philpot Lane, E.C. on April 28th, Sir George A. Pilkington, chairman of the directors, presiding.

Mr. J. F. ANDERSON (of Messrs. Lyall, Anderson & Co., the agents and secretaries) having read the notice convening the meeting.

The CHAIRMAN said:—Gentlemen, it is my pleasure to move that the report and accounts as presented to the shareholders be received and adopted. The report and balance-sheet as you have it here is so full and complete that to my mind there is very little that is necessary for the chairman to say upon it. I cannot help complimenting the secretaries upon the extremely able and explicit manner in which these accounts are presented. There seems to me little or no need to enlarge upon them, although at the same time I shall be extremely pleased to answer any question which any shareholders may put to me. You will see a considerable falling off in the estimate in the matter of coffee, and I am afraid in the future we must look for a still further falling off in that department of our produce. For years and years past the Island has suffered enormously from the falling away of coffee, and we in the Poonagalla Valley have held on longer than any other part of the Island. Eight years ago I was told that we must not look for a continuation of coffee for more than a year or two at the outside, but every year we have had our rotation crops, and up to last year they have been a very considerable source of income. But it is a decaying source, getting worse and worse, and I am afraid we have now arrived at the time when we can look for no income from that department. We have tried to take time by the forelock and have planted tea under all existing coffee, so that by the time it is entirely done we shall have tea taking its place. The great difficulty in Haputale is the want of roads. We have been fighting with the Government to get better roads throughout the neighbourhood, and in a short time we shall be in a very much better position than we are in now. The Government have consented to construct a road and bridge which will lead right up to the very door of the Poonagalla factory, and by a system of wire shoots, which will extend all over the estate in time, the whole of the produce will be carried down to the factory by their

The following are additional particulars from the Prospectus of this Company:—In addition to the estates mentioned, 630 acres of forest land have been purchased direct from the Government of His Highness the Maharajah on the Company's behalf, by the vendors, and will be transferred at cost price. Cabel advice has been received of the purchase of Woolbeding estate, situated in close proximity to the above

scheduled properties, with an approximate acreage of 148 acres tea planted 1888-1896, 93 acres coffee, 174 acres jungle and grass. Total 418 acres, for the sum of £8,000, payable half in cash and half in shares. Negotiations are in progress for the acquisition of other lands, and about 700 acres are being cleared for planting up with tea during the current year. There are factories on Bon Ami and Woolbeding estates, the former of which it is proposed to considerably improve, and another factory will at once be begun on the Mount estate. The tea-making machinery is sufficient for present requirements, but will be added to as the newly-planted lands come into bearing.—Local "Times."

TEA AND TEA COMPANIES.

(From a London Correspondent.)

London, May 7.

CEYLON TEA COMMITTEE.

A meeting of this Committee was held on Monday to consider several questions of importance, including the appointment of a chemist, for which there were applications, in view of the recent Committee in the *Observer* in respect to the alleged falling off in the quality of the tea grown. Nothing definite was however decided upon.

The question of garden bulked tea, and the correspondence that has taken place in reference thereto was also under consideration, the Committee having been asked by the London Wholesale Tea Dealers to invite discussion, but the Committee decided that they could do nothing more and must leave the matter in the hands of the tea planters themselves to deal with and to guard against the objections raised.

The following is the resolution come to by the Indian Association of which Mr. Ernest Tye is Secretary:—"The Committee have assured the trade that importers will do all in their power to meet the reasonable requirements of buyers in this matter but must leave the question of printing words in the catalogues to those concerned." The resolution virtually represents the attitude of both the Ceylon and the Indian Associations.

The Anglo Ceylon and General Estates Company Limited, have changed their address from South Sea Chambers, Bishopgate St. to 20 East Chap.

TEA TRUST COMPANY.

It is understood in well informed circles in London at an early date a very influential Trust Company will be formed for the purpose of dealing in tea shares and other securities in connection with Ceylon and Indian properties. It is probable that the prospectus will be issued very shortly and that the capital will be £250,000. The names of Messrs. Taylor and Ogle are associated with the Secretaryship, and this gives a sufficient guarantee of the stability and genuineness of the concern.

CEYLON TEA IN AMERICA.

The circulars issued by Messrs. Gow, Wilson and Stanton show the very great and encouraging increase of shipments to America. Those for the quarter of the year just ended are practically double of those that took place in the same quarter of 1896.

LONDON TEA SALES.

It was decided to divide the large auction sales catalogued for Tuesday and to sell half the quantity then and half on Thursday. The market still showed an upward tendency, though the quality of the tea was not so good, taking it all round. There were 21,330 packages offered on tea.

The Share Market is a little more active. People are beginning to take a more hopeful view of things both in South Africa and in the East. And there is an increased demand for shares. Fair amount of business has been done in Eastern Produce, the recent annual report of which was regarded as very satisfactory. The report of the Scottish Ceylon Tea Company has also created a favourable impression.

The shares of the Travancore Tea Company, issued at the instance of the Ceylon tea plantation shareholders were over applied for. It is regarded as likely to turn out a very good thing. Mr. W. Mackenzie who was one of the vendors was very much pleased with the result.

NEW ISSUES.

The Acme Tea Chest Company, Limited with a capital of £150,000 in 75,000 six per cent. cumulative preference shares and 75,000 ordinary shares of £1 each, has been formed to acquire the business of manufacturing and selling steel tea chests, hitherto carried on by the Acme Package Company, Limited, together with the works, plant, machinery, patent rights, contracts, and other assets of that company, which recently acquired works at Polmadie, Glasgow, and equipped them with special machinery equal to an output of 20,000 to 24,000 chests per week. The formation of a new company, with larger capital, has been resolved upon, the prospectus states, mainly with the object of putting the company in a position to manufacture its own steel sheets. The purchase price has been fixed at the sum of £112,500, payable as to £25,000 in ordinary fully-paid shares, as to £25,000 in six per cent. cumulative preference fully-paid shares, and the balance of £62,500 in cash. There are now offered for subscription 50,000 preference and 50,000 ordinary shares.

PLANTING NOTES.

A BRAZILIAN PROVERB says:—"Coffee to be good must be as black as night, bitter as death, and hot as sheol."—*American Grocer*.

NEW CORN PRODUCT.—The discovery that the pith of the corn stalk can be used in the construction of war vessels is likely to be of benefit to agriculture in more than one way. The chief use of this pith is for a packing between the inner and outer shells of the vessel, so that when pierced by a projectile it will absorb water and swell so rapidly as to close the opening before the vessel leaks to a dangerous extent. Experiments with this pith have been so satisfactory that it has been adopted in the construction of all our new vessels of war, and European nations have commissions for investigating the same material, so that the use of corn pith will make a market for what was once a waste product. In the process of extracting this pith the blades and husks are removed, and the stalks are cut into small pieces. When the pith is taken out from this stalk, the remainder is ground up into a flour-like substance which resembles bran. Some experiments with this "new corn product," as it is called, have been made at the Maryland Station with the remarkable result that it is found to contain eleven per cent. more of digestible matter and two per cent. more of digestible protein than the whole fodder does when shredded. It contains as much digestible matter as the corn blades, and more total digestible matter and half-of-one per cent. more protein than Timothy hay. It does not contain as much digestible albuminoids as Wheat-bran, but it equals that food in the total amount of digestible matter. It keeps as well as bran or Cotton-seed meal. It is in such condition that it can be uniformly mixed with any ground grain, and when used as a base it is possible to make a complete and normal ration for stock in one bulk without the necessity of feeding grain and hay separately. Animals fed upon such a ration eat it with relish, and keep in normal condition. Since there is only one pound of pith to fourteen pounds of blades, husk, and stalk, this new material amounts to a very considerable portion of the fodder.—*Garden and Forest*.

ROYAL BOTANIC GARDENS:
ADMINISTRATION REPORT OF MR.
DIRECTOR WILLIS FOR 1896.

ENCOURAGEMENT FOR PARA RUBBER CULTIVATION.

THE first Administration Report of a new Director of the Royal Botanic Gardens is always regarded with special interest. It usually affords an indication of the tastes of the writer, and of the direction in which he expects to make himself most useful to the Government and the Colony. Mr. Willis follows three notable men—two of whom, at least, achieved a European reputation for their scientific attainments. The list includes the late Dr. Gardner, Dr. Thwaites, and Dr. Trimèn. We need not dwell on what the Colony owes to each of these Directors; but we may say that, perhaps, Dr. Trimèn best combined his love and pursuit of science with the desire to do his best for the country by "Notes on Economic Plants," by experimental Gardens at different elevations, and by readily attending to private enquiries, for the benefit of the planting and general agricultural industries of the Colony. It was in his time that the Badulla, Heneratgoda and Anuradhapura Gardens were established. We need scarcely refer to the notable scientific work done by Drs. Thwaites and Trimèn. The former gave botanists a very full and learned compilation on Ceylon plants; while the latter in a far more popular, and yet truly scientific form, very nearly completed his Ceylon "Flora."

Now, it is a fortunate thing for the Colony and, from what we think we discover of his tastes, for Mr. Willis, that the way has thus been cleared, so far as purely scientific work is concerned. No doubt, Kew and Botanists elsewhere will be making their demands from time to time; no doubt there are new forms of plant life still to be discovered and described even in Ceylon. Certainly there must be many "life-histories" of importance, scientifically, to be worked out. But the great matter is that there is no special and purely scientific work laid on Mr. Willis as a duty, and that he is therefore free to give himself to the department of Economic Botany to which his choice naturally inclines. This is truly good news for our planters and agriculturists generally, and we congratulate them on the full evidence afforded, again and again, in this opening Report, of the good work which Mr. Willis,—if health and strength are spared—is prepared to attempt, and, if possible, carry out for them.

For ourselves, we may say at once, that we have seldom read a Report that has given us more satisfaction. On Monday we gave our readers a taste of Mr. Willis's "Economic Notes." His moderate but wise words on our Tea industry will have been duly noted by the Government, and by the planting and mercantile community; and all he tells us of Rubber is much to the point and will afford the best possible guide to intending cultivators. Dr. Morris has lately been telling Jamaica planters he could not seriously advise them to commence cultivating "rubbers" in view of the enormous development behind Lagos and in other parts of Africa of sources of supply from original forests. And there is no doubt much in this, especially in regard to the West Indies, where they have (at least in Jamaica) the prospect of cultivating a variety of products for the immediate supply of the finest market in the world

namely the United States. But in Ceylon Mr. Willis's sober statement of fact is by no means discouraging to the actual, or intending, rubber planter. Indeed, 50 trees of Para rubber per acre, well cared-for, should yield after ten years a regular annual harvest of 100 lb., worth £12 or £13 (or even £10) in London,—rubber culture would be preferable to, and far more profitable than, that of coconuts. The expense of attending to 70 to 80 palms, harvesting, etc., must be as great as that of dealing with 50 Para trees, including tapping, etc.; while the gross return, even at a liberal estimate for the nuts, is well-nigh 100 per cent more in the case of rubber. There is, therefore, clear encouragement to go into "rubber" with the Para kind, provided suitable land be carefully selected and the work of planting properly attended to.

Turning now to the Report generally, it will be noted how practical is the view taken by Mr. Willis of his several Gardens. He regards them all with interest and as serving a special purpose with reference to the agricultural and general public, although the Heneratgoda Garden may, perhaps, be considered his favourite. He is quite prepared to extend their usefulness, and Mr. Willis's references to the necessity of experimental plots, to the work of the Agricultural Chemist, and especially to the distinctive character of "tropical agriculture," show that he is fully alive to the way in which practical aid can most truly be extended to the planters and other Agriculturists of the Colony. But clearly Mr. Willis will want help, and that of Experts, to co-operate with him in several departments. He plainly indicates where the Analytical Chemist comes in, as also the Entomologist—for insect pests ought to be thoroughly investigated—and no less the Fungologist. Give Mr. Willis the hearty co-operation of a "Scientific Agricultural Board"—such as we have been advocating—and we feel sure he and they will soon show the great practical value of their labours to a Colony like Ceylon, so pre-eminently dependent on "tropical agriculture." In every branch of our planting—in hill or lowcountry—and rice, fruit, fibre and vegetable culture by natives, we see room for investigation and experiments such as could not fail to yield notable results. Such a Board would help Mr. Willis and his able Assistants, Messrs. Nock and Macmillan, to turn the Gardens to far more practical use. It would also help Government and the Colony to a really successful, because liberally and scientifically supported, Agricultural School—not a half-starved crippled institution such as now exists. Planters could fearlessly go for such a "Board" for advice and instruction, to have pests examined, diseases worked out and remedies fully tried. Capital, time and labour would be saved in many directions through seasonable warnings given—as in the case of unsuitable situations for cacao gardens, &c.—or through the demonstration that it would be wiser to abandon one and try another new product, than to go on in the old groove leading to disappointment and loss.

But we must close with a word of thanks to Mr. Director Willis for his full, interesting and suggestive, first Annual Report—may many more follow from the same pen—and also some acknowledgment to Mr. Nock of the Hakgala Gardens for much useful information—some of which we quoted—in reference to the work he so conscientiously and admirably carries out at our Hill Gardens *par excellence*.

(Extracts from Report of the Director for 1896.)

SECTION I.—CHANGES AND MOVEMENTS IN THE STAFF.

During the early part of the year Mr. Nock, Superintendent of Hakgala Garden, acted as Director. The late Director, Dr. Trimen, returned from leave in England on March 8, still in very poor health, and retired on pension on June 30. A special allowance was voted to him for the remaining six months of 1896 to bring up his pension to the equivalent of full pay, and enable him to remain in the Colony to work at the last volume of his *Flora of Ceylon*. He persisted in this work in despite of great physical infirmity, but unhappily did not live to see its completion. He died at Peradeniya, somewhat suddenly, on October 16, 1896, and was buried in Kandy.

From July 1 to September 14 Mr. Nock again acted as Director. On the latter date I arrived from England, and at once took over charge of the Department. Some months were naturally spent in familiarizing myself with all the details of the condition and working of the Gardens, and no changes of importance were initiated until towards the end of the year. I subjoin, according to precedent, a brief account of the general condition of the Gardens, indicating those directions in which I have begun or contemplated any change.

2.—GENERAL CONDITION OF THE GARDENS.

PERADENIYA.—The area not occupied by offices, stores, bungalows, &c., is about 120 acres, employing about 100 coolies. Of these men many are employed in road-making (there are about $4\frac{1}{2}$ miles of carriage roads and 2½ miles of footpaths), sweeping, grass-cutting, &c. Of the great beauty of the garden little need be said here, except that any change which would injure it is much to be deprecated on every ground, artistic or utilitarian. The number of visitors from other countries is large and increasing, and would probably be even larger were there any accommodation at Peradeniya.

The general condition of the garden is excellent, considering the drawbacks which have to be contented with; the chief of these are poor soil and want of manure and water. It would be hard to choose a worse site in this neighbourhood for horticultural work, the southern end of the garden is very rocky with shallow soil, and the northern part is composed almost entirely of old river deposits of gravel and sand. The beautiful sylvan character of this part of the garden is deceptive, giving the impression of a rich soil rather than the reverse. Most of this land (some 60 or more acres) is quite unsuited to the cultivation of anything but hardy shrubs or trees. It is now occupied by the Arboretum, a collection of trees and shrubs from all tropical lands. These are not at present arranged in any very systematic order, but the greater part of the ground is appropriated in plots of suitable sizes to the various natural families of plants. When a new tree is planted it is placed in its proper systematic position in the Arboretum, and in felling trees care is taken to remove those occupying wrong positions in the grouping. This process has been going on for ten years or more, and ultimately it will result in a properly classified Arboretum, where it will be easy for visitors to find any desired tree instead of having to search as at present over 60 acres of ground. The south end of the garden also contains many young trees, but these were properly arranged at the time of planting. The Arboretum contains about 800 jak and sapu trees, which are used for timber and firewood, new ones being started as old ones are cut down; it is intended gradually to eliminate these trees from the regular Arboretum, and confine them to a timber reserve in one part.

The second great natural disadvantage is the want of water. Owing to the position of the garden in a river bend, and to the formation of the land itself, there are no streams within the garden, whilst the river is at too low a level to be available. All the water supply is brought from a distance in pipes (often blocked by heavy rains), and is distributed

over the southern part of the garden in small bricked channels. More of these are wanted, as well as an increased water supply. A branch pipe to the bungalows is desirable, water at present having to be carried long distances.

The buildings in the garden are numerous; the bungalows, Museum, &c., are kept up by the Public Works Department, and are at present in fair order; the remainder are maintained from the garden vote, and I found them in urgent need of repairs, which were taken in hand at once. The chief of these buildings are (1) the cattle shed, (2) the octagon house, (3) the conservatory, (4) the glass-roofed plant house, (5) the fern house, (6) the carpenter's shop, (7) the cart shed, (8) the Gardner memorial, (9) the Thwaites memorial.

The gardening staff, apart from coolies, consists of five "selected coolies" (50 cents a day), who do more skilled work than ordinary coolies, 4 "gardeners" (R12 50 to R15 a month), 1 "upper gardener" (R17 50), 1 "kangany" (R15), 2 "plant collectors" (R20 and R35), and 1 "head kangany" (R55), besides the European Curator. The plant collectors act as kanganies or gardeners when not on tour. Most of the officers mentioned are rather kanganies than gardeners and there are few who are capable of doing really skilled horticultural work. It was hoped when the class of upper gardeners was created a few years ago that a supply of educated young men would be drawn to the Gardens to learn the work, and that they would afterwards be able to get well-paid posts in other employ as gardeners. This hope has not been realized. Of the three posts of this nature, the two upper (at Hakgala) are still held by their original occupants, whilst the successive holders of the third (Peradeniya) post have left the Department to compete for clerkships in other branches of the Public Service. It is a pity that this should be so, but there is no opening for skilled gardeners in the Colony outside of this Department. If good work in horticulture and experimental cultivation is to be done, it is absolutely necessary to have educated and well-trained gardeners, and this is impossible if the best that such men can obtain is a salary of R20 or R25 a month; the better-paid posts in this Department are so few that a man can rarely get one before he is forty or forty-five years old. At present if any really skilled work has to be done, it falls to the Director or Curator, whose time should rather be devoted to general superintendence and to the initiation of new work. The most important work of the Department is in this way much handicapped.

HAKGALA.—The total area is 550 acres, mostly jungle and pataua. The cultivated area is about 25 acres, employing about 50 coolies, besides 2 "upper gardeners" and 1 "clerk and foreman." The garden is upon a steep slope with much rainfall and rather poor soil. A considerable part of it is devoted to the cultivation of ornamental plants, and forms a pleasure resort of extreme beauty, in great favour with residents and visitors at Nuwara Eliya. A good deal of land is occupied by nursery plots for the growth of flowers and vegetables for stocking the garden and for sale to the public, and other portions are used for experimental cultivations of economic plants, &c. The general condition of the garden is excellent in every way in spite of the ravages of deer, &c., from which protection is much needed. The garden has proved of much service in the introduction of economic plants into Ceylon (notably cinchona in the past and many fruit and vegetables in recent years). Its great elevation renders it, however, of use to a comparatively limited area of country.

HENARATGODA.—This little garden of 39 acres, employing about 12 coolies and a native conductor, is one of the most useful in the Department. Its higher night temperature renders it much more favourable to the growth of tropical plants than Peradeniya, and it has a good rainfall and fair soil. Most of it is devoted to the growth of important economic plants suited to the wet low-country districts. An increased labour vote is urgently required, as well as a new visitors' shed and room for carrying on experimental

work. A wire fence to prevent cattle trespass is also a necessity. This garden was originally opened as a nursery for Para rubber, and an immense number of plants of this species are now cultivated in Ceylon and the East, the progeny of the original trees still at Henaratgoda. Many other cultivations have been added to this, and the garden now contains a fine collection of useful and ornamental plants, and deserves to be more visited than it is, considering its easy accessibility from Colombo and elsewhere. The process of rubber-tapping may be seen early every Saturday morning, and there are many objects of interest, including a few acres of original jungle.

ANURADHAPURA.—This little garden of 15 acres, employing about 6 coolies and a native conductor, is very pretty and well stocked with plants, but often suffers from floods or drought. The extreme apathy to improvement of the surrounding native population renders the garden of less use than need be, but an improvement in this respect may be hoped with the opening up of the country and extension of irrigation works. It is the only garden we possess in the extensive dry country ($\frac{2}{3}$ of Ceylon), and I am strongly opposed to its abandonment, even though at present its success seems but little. Many plants grow well at Anuradhapura that do badly in the wet region, and we may yet hope to see many important cultivations in this at present thinly inhabited country.

BADULLA.—This garden occupies 11 acres, employing a conductor and about 6 coolies. It was opened in 1836, and so is yet very young. It was thickly planted with every kind of plant likely to grow well, and now requires thinning. Many plants thrive well here, and it is hoped that the garden may prove of much use in the Province of Uva. The climate of the eastern side of the mountainous district is so different from that of the western that experience gained in one district is not always applicable to the other. Some details of interest with regard to the growth of trees, &c., are given in the detailed report below.

Speaking generally of the last three gardens, their most urgent wants are increased labour (the staff of coolies at present is barely enough to keep them in tidy condition), wire fences (except at Badulla), coolie lines (except at Henaratgoda), and a new visitors' shed, &c., at Henaratgoda.*

3.—THE WORK OF THE GARDENS.

Under this heading fall to be considered some aspects of the work carried on in this Department other than mere routine. The chief are (1) the introduction into Ceylon of economically important plants, and the carrying out of experiments upon their cultivation; (2) other scientific work upon the Ceylon flora, diseases of plants, their physiology, &c.; (3) the sale of plants to the public.

(1) **INTRODUCTION INTO CEYLON OF NEW AND IMPORTANT ECONOMIC PLANTS: EXPERIMENTS IN CULTIVATION, &c.**—This is one of the chief objects kept in view in the working of the Department, and every effort is made to carry it out in spite of all hindrances. Much has been done in the past and is being done in the present, but it is desirable that the usefulness of the Botanic Gardens in this direction should be increased continually, and it will be well, therefore, to consider the chief obstacles to this increase, which are the want of skilled labour and of suitable areas of good land.

The available labour force is chiefly consumed in keeping the Gardens in good order—weeding, watering, grass-cutting, sweeping, road-making, repairing buildings, culverts &c. propagating and planting out, and so on. Properly to carry out extensive cultural experiments would require an increased labour supply, especially of a skilled kind. As explained above, most of our native gardeners are not capable of attending to such skilled work as selection of parents, propagation from choice shoots or seed, hybridization, cross-fertilization, and so on. So long as all work of this kind

must be personally done by the Director or Curator, it will be impossible for the gardens to do very much in the advancement of skilled scientific horticulture or planting in the Colony. In this connection I would again draw attention to the needless waste of much of our skilled labour involved in propagating and selling common garden or verandah plants. If this were given up, much more could be done in useful cultivations. To cultivate and experiment upon an economic plant upon a scale sufficient to give really reliable results requires that a large area shall be devoted to it; thus over 4 acres of good land have been given up to Para rubber for nearly twenty years, and it is intended to plant another acre for experiment in 1897. The good land in these Gardens, suitable for such work, is very limited in area, amounting to, perhaps, 48 or 50 acres in all the Gardens together. It is evident, therefore, that the amount of land given to each of the numerous useful plants at present cultivated or on trial must be very small. At Peradeniya in particular there is very little good land available, perhaps 15 acres in all, much of which is occupied by nurseries, vegetables, fruits, &c.

An annual vote of R500 is allowed for the purchase of plants and seeds, chiefly of course from abroad. Much of this at present has to be spent in keeping up the supply of roses, &c., for sale to the public, for such plants so soon deteriorate in Ceylon. If this trade were abandoned, much more might be spent on useful seeds, &c.

It will be of interest to give here a list of the chief cultural experiments at present in progress upon any important scale:—

(1) **INDIARUBBER.**—The Gardens contain a large collection of rubber trees of all kinds. About $3\frac{1}{2}$ acres at Henaratgoda are devoted to experimental plots of Para rubber (*Hevea brasiliensis*) of various ages. There are many hundreds of thousands of trees now in cultivation in Ceylon and elsewhere, but none are yet ready for harvesting. In anticipation of the time when this will be the case I have commenced an important series of experiments at Henaratgoda, with a view to solving, if possible, the following among other questions: (a) How often should a tree be tapped? (b) What are the best times of year and of day to tap? (c) What is the best method of tapping? (d) What is the best way of curing the rubber for the market? (e) What is the effect of manure and other circumstances on the yield of rubber? (f) Can rubber be profitably obtained from the leaves, and if so, how best? (g) What is the labour-cost per pound yield? and so on. These experiments will probably continue over several years, and results will be published from time to time. They are again referred to below under economic plants.

(2) **COFFEE.**—Several plots of various kinds of coffee are being cultivated at Peradeniya and Henaratgoda with the view of determining the kinds best suited to cultivation in Ceylon, where disease is so prevalent. It is eminently desirable that a larger area be devoted to each, and that careful breeding, selection, judicious hybridization, &c., be carried on to obtain, if possible, hardy varieties suited in Ceylon. This, however, is impossible without more skilled labour.

(3) **CACAO.**—A number of plots of different kinds are on trial. The remarks made in the last paragraph are equally applicable here.

Other plots are devoted to (4) *Sisal Hemp*; (5) *Gambier*; (6) *Camphor*; (7) *Coca*; (8) *Vanilla*; (9) *Nutmegs*; (10) *Pineapples*; (11) various shade and timber trees.

(12) **GARDEN VEGETABLES.**—A good deal of land is given to native and foreign vegetables. It is very desirable that experiments in the breeding of improved forms of tropical vegetables should be instituted, but the work requires skilled labour, space, and much manure.

(13) **FRUITS.**—Many European fruits are on trial at Hakgala, and tropical fruits in the other Gardens. The remarks made on vegetables apply here also. Cultivation is rendered very difficult by constant theft of the fruit.

* The votes for labour, &c., have been increased for 1897 from R2,200 to R3,000 at Henaratgoda, from R1,200 to R2,000 at Anuradhapura, and from R1,500 to R2,000 at Badulla; and a special vote has been sanctioned for wire fences.

In this connection I would draw attention to the desirability of greater communication and co-operation between the Gardens and those whom they are designed to benefit. More effectual means of bringing before those who are interested in them the advantages offered by this Department, and the results of work done, or particulars of work being done, in the Gardens are very desirable. And, on the other hand, it is also much to be desired that the Gardens should be kept better informed of all that is going on in planting and cultivation of all kinds in different parts of the Colony. I hope, before long, to complete my organization of a scheme for the attainment of both these ends.

(2) OTHER SCIENTIFIC WORK.—Under this heading I have grouped together all the other branches of scientific work carried on in the Gardens; many of these, though of much importance, have received but scant attention in Ceylon.

The native flora has been very fully studied, and when the remaining volume of the late Director's "Flora of Ceylon" is completed, the Colony will be in possession of a really first-class handbook to its native plants, and their local uses. To provide such a work, as well as a good reference Herbarium and a collection of drawings of the native plants, is one of the first duties of a Botanic Garden. This work is now approaching completion, and the energies of those officers who have been engaged with it may now be gradually diverted to new fields of scientific work. The further elaboration of the details of the Flora can now be left largely to local botanists, aided by occasional collecting tours by the staff of the Department, especially in those districts which are as yet insufficiently explored. It may be remarked however, that the construction of a Flora is only the beginning of a proper scientific investigation of the botany of Ceylon, and that there is an unlimited field for further observation and research.

Important work has yet to be done in the study of the economic uses of native Ceylon plants as sources of food, fruit, fibre, drugs, &c. It is intended to devote a certain amount of land to such questions but there are very many which require the aid of chemical or other experts.

Cultivation in the tropics is carried on very much in the dark, and very little is really known about it. A consideration of its general state, and an application of the knowledge gained in the temperate zones, point almost irresistibly to the conclusion that if really permanent success in agriculture is to be attained, such subjects as rotation of crops, scientific manuring, and so on, must receive as much attention as in Europe. For such work, however, the aid of the chemist is indispensable.

Another direction of work is the study of the diseases of plants in Ceylon, whether they be the result of animal or vegetable (fungoid) parasites, the latter especially. The spread of reliable information among cultivators as to the real nature and meaning of diseases is much to be desired. The experience of the coffee disease has clearly emphasized the general principle that it is but rarely that there is a specific cure for a specific disease, but that we must rather trust to "prevention," or aid nature in throwing off the disease. Much harm is done in this direction through ignorance or selfishness, and it is hoped that this Department may aid in the dissemination of sound knowledge upon this subject.

The advance of scientific agriculture in Europe and America is largely due to research in vegetable physiology and in allied subjects. It is very desirable that such work should be conducted to a larger extent in the tropics, where much of the experience gained in Europe is of no avail, owing to the different climatic conditions. Many botanical experts and students visit the tropics every year for such work, and it is very desirable that every encouragement be offered to them to choose Ceylon as a field of work. The laboratory here is, however, very small, and needs extension.

Another branch of work recently commenced in the Department is photography. A dark room is being fitted up at Peradeniya for the purpose. The

usefulness of the art in all scientific and horticultural work needs no explanation.

(3) SALE OF PLANTS TO THE PUBLIC.—The Gardens sell not merely economic, but also ornamental and other plants and seeds at low prices. The sale of economic plants is of course one of the chief duties of the Department, nor can any objection be made to the sale of such ornamental and other plants as cannot be got from local sources, nor to the sale of any plants whatever at the outlying Gardens; but there is no good reason why the time of the most skilled men at Peradeniya and Hakgala should be largely taken up in propagating and selling plants of the commonest kinds at low prices. Such work should be left to local florists and nurserymen. The revenue thus obtained is small, the cost of its collection is large, and it does not even come to the Department at all.

PERADENIYA GARDEN.

ROADS AND PATHS.—The main drive, for a distance of 135 yards from the entrance, and the monument road, were thoroughly repaired in January and February. A road was made leading up to the Curator's bungalow.

BUILDINGS, &c.—The site of the old Head Gardener's bungalow, close to the public road was taken in hand in February and transformed from an unsightly mass of ruins to a tennis court, bordered by a bank of turf. Most of the buildings in the garden, other than those kept up by the Public Works Department, being in a more or less ruinous condition, were taken in hand in the latter quarter of the year. The work of rebuilding and repairing them will continue into 1897. The cart shed, whose roof was only prevented from falling by the support of a large tree at one end, was rebuilt in a stronger form. Soon afterwards the carpenter's shed entirely collapsed during heavy rain the whole structure with most of its contents being destroyed; fortunately the accident occurred on Sunday, when there was no one in the building. This is also being substantially rebuilt. The roof of the cattle shed was also in a dangerous state, and much of this structure has been rebuilt. The fernery roof also proved to be rotten; new timber was cut from trees in the garden and the entire roof was rebuilt. The carrying out of these repairs involved a large outlay, which was met by saving on other votes than "Pots, Tools, &c." The other buildings of the garden also require repairs, e.g., the Museum, Herbarium, Director's and clerk's bungalows, and others. The bank at the back of the Curator's bungalow was cut down to a gentler slope and turfed; an immense improvement was thus effected in the appearance of this part of the garden.

LANDSLIP.—The heavy rains in December caused a flood in the Mahaweli-ganga on the 17th, resulting in a very extensive landslip at the end of the cooly lines. The position of these buildings is now a dangerous one, and requires early attention.

CULTIVATION &c.—A good deal of labour was spent in levelling and extending the space behind the stores where the plants in bamboo pots are kept. A number of large trees were cut down to give more room and light.

Special attention was given to the nursery in the early part of the year: the paths were levelled and straightened; the beds were forked up, manured, and stocked with as large a variety of useful plants as they could hold.

A considerable addition was made to the kitchen garden, and a very full collection of native and foreign vegetables and medicinal plants put out in it.

The following species flowered here for the first time in 1896, viz., *Abroma fastuosa*, *Ægiphila Martinicensis*, *Aphelandra nitens*, *Baphia* sp., *Barleria lupulina*, *Bromelia Pinguin*, *Calpurnea aurea*, *Ceratopthea triloba*, *Cyanotis kewensis*, *Diacrinum bicornutum*, *Eranthemum elegans*, *Faradaya splendida*, *Hibiscus micranthus*, var., *Ixora illustris*, *I. salmonea*, *Justicia Armstrongii*, *Phyllarthron comorense*, *Randia maculata*, *Saintpaulia ionantha*, *Victoria regia*. The last-named is worthy of special remark; it was grown

on a mound of earth and compost formed in the warmest part of the pond; it began to flower on November 3, and at the time of writing (April, 1897) is still in bloom.

WEATHER.—An unusually wet year on the whole, especially in the north-east monsoon. The total fall was 28.72 in. above the average of the past ten years. The greatest fall in any twenty-four hours was 6.58 in. from December 15 to 16.

VISITORS.—The total number of visitors for the year is approximately 18,000: the book kept at the lodge was signed by 2,520 persons not resident in Ceylon, the largest number on record, and an increase of 237 over last year. A number of seats have been provided for the convenience of visitors, and have been much appreciated.

GUIDE BOOK, LISTS, &c.—The last edition of the "Hand Guide" will soon be exhausted. I find that the sales of this work are almost entirely to extra-colonial visitors, and I am therefore preparing a smaller and cheaper edition in the hope that it may prove of more use locally. A number of copies of the "List of Plants cultivated at Peradeniya" still remain, but the list is now very incomplete, and material is being collected for a new one. A list of seeds available for exchange or sale is also in preparation, and will, it is hoped, be ready for the press early in 1897. Another desideratum is a new Catalogue of the Library, the old one being very incomplete indeed.

5.—HAKGALA GARDEN.

The following extracts from the full report of the Superintendent show the chief work that has been done during the year:—

NURSERIES.—The usual stock of ornamental and useful plants has been kept up in the nurseries, and large quantities have been distributed to different parts of the Island. I regret to report that many thousands of small plants and seedlings were destroyed both in the nurseries and in the borders by the excessive rainfall during the latter part of the year; the foggy, sunless, wet weather for almost three months together proved too much for many introduced plants. Geraniums especially suffered this season; this was to be expected when for days together the heavy rain silted the soil up the stems as high as six to nine inches.

A wattle fence was put up all round the new nursery. Such a fence keeps out hares and larger animals for a time, but in a damp climate like this it soon becomes decayed and useless, and much labour is required to keep it in repair. I trust we shall soon be allowed a permanent and effective fence of wire and wire netting.

The beds of Turkey oak (*Quercus cerris*) mentioned in last year's report have grown well, and are now ready for distribution; they are nice, strong, little plants, and will be useful and interesting for planting round up-country bungalows.

About 100 scions of plums and apples were grafted on to common stocks, and the greater part of them have taken well.

A good supply of Cherimoyer seeds was presented to the garden in October by Mr. John Tily, of Dimbula. Most of these were sown in beds and boxes, and the remainder sent to the Badulla and Peradeniya Gardens.

Over 900 packets of seeds were sown in seed pans and boxes, and several beds of seeds were sown in the nursery. No fewer than 50,136 seedlings were pricked out or transplanted during the year, 83,703 cuttings were planted in the nursery and propagating house, and 6,886 plants potted.

CLASSIFIED HERBACEOUS GARDEN.—By far the heaviest piece of work during the year has been the making of an entirely new herbaceous garden. This has been made upon the old site; it is irregular in shape, measuring 130 ft. in its greatest length, with an average width of 57. The slope of the old garden was very steep; the gradient of the new one is only 1 in 60. A turf bank, 120 yards long and from 1 to 10 ft. deep, was formed all along the lower side, and the upper part cut down in a correspond-

ing degree. The garden is divided into two parts by a rock bank 4 ft. high, and the two parts are connected by a flight of steps. Other flights of steps, five in all, lead out of the garden in various directions.

The garden is laid out into 45 beds 4 ft. wide with paths $2\frac{1}{2}$ ft. wide between them, and with a wider central path. The beds are edged with small red tiles, specially made for the purpose at Mahagastota brick kiln; these form a neat and inexpensive edging. The total length of the paths is 318 yards and of edgings 682 yards. About 800 species of herbaceous plants have been set out in their proper places according to their natural orders, and most of them are doing well. It will of course be some time before all the beds are filled up. The hard, steep bank at the upper end has been planted with a variety of suitable plants in small pockets.

ROSE GARDEN.—The old rose garden, made in 1884, was found to be on too steep a slope. The plants in it being worn out, it was decided to reduce the slope and make a new garden upon the same site. The new garden forms a circle 61 ft. in diameter, with a gradient of 1 in 60; a large quantity of soil was excavated and used to fill in the hollow below. A central drain, 3 ft. deep and 33 yards long, with six cross drains, each 30 ft. long and 2 ft. 6 in. deep, was made; each has a stone "box" drain, 4 inches square at the bottom. The whole plot was dug to a depth of 2 ft., and the bad soil replaced by better. The bank which runs round three-fourths of the plot was finished to an angle of 45 deg. and turfed; two flights of steps were built upon it. During the early part of December the garden was laid out into beds 6 ft. wide, with paths 4 ft. wide, and verges of English lawn grass. The weather was, however, too wet for planting. A collection of 120 varieties of roses was received at the end of the year from Messrs. Smith & Co., of Worcester, and these, with others, will be planted early in 1897.

FOOT AND-MOUTH DISEASE.—This disease broke out at the end of August; nearly all the cattle suffered from it, and one weak old cow died.

PORCUPINES.—These destructive animals paid us a visit in July and did much damage to plants of the Lily and Iris families, especially *Moraea iridioides*. In November they came again and completely destroyed a large number of handsome clumps of Wedding flower (*Moraea Robinsoniana*.)

VISITORS.—The number of visitors during the year was 1,568, against 1,528 last year. The largest number in any one month was 248 in April, the smallest 33 in July.

WEATHER.—1896, rainfall, 110.04; days, 220; 1895, rainfall, 94.15; days 205; average rainfall, 90.78; average days 207.

HENERATGODA GARDEN.

This is a most valuable and interesting garden, and it is to be regretted that it is not more often visited, considering its nearness to Colombo. The garden is well kept, but much more might be made of it were the labour force slightly increased and a regular supply of manure ensured; without the latter no real cultivation of the many important plants contained in the garden can be carried on. Cattle trespass continues to give much trouble, and will do so until a barbed wire fence is placed around the garden. Labels also are much wanted. The bridge outside the entrance is becoming dangerous and requires repair.

WEATHER.—The following table gives the rainfall for the year; the last quarter was unusually wet:—

Total, 1896, 103.78 in. on 173 days, against 112.71 on 154 days in 1895.

7.—ANURADHAPURA GARDEN.

This pretty little garden is in good order, with the exception of the buildings, which are in a ruinous condition. The chief requisites are increased labour supply, new cooly-lines, repairs or rebuilding of the conductor's bungalow, a wire fence, and a supply of manure. The garden suffers in usefulness from the apathy of the inhabitants, but it may be hoped that with the opening up of the country and the extension of irrigation this will not always be so.

VEGETABLES.—As at the other gardens, I began in the last quarter of the year to make a collection of vegetables of all available kinds, for introduction among the villagers and others. The Government Agent, however, having opened a vegetable garden upon a larger scale than anything that we could attempt, most of the seeds and plants have been handed over to him.

BADULLA GARDEN.

Like the two last-named, this garden suffers chiefly from want of labour and of manure. The cooly lines are in a very bad state and require rebuilding, and the shed is also out of repair. A good stock of plants is now available for distribution, but there are few applicants.

TREES &c.—Most of the trees have made good progress, and as many of them are now nine or ten years old, it may be useful and interesting to give the names and measurements of a few of the fastest-growing trees, which may be useful to those wishing to plant in this locality:—

Of Conifers, *Cupressus torulosa*, *C. macrocarpa*, *C. Lawsoniana*, *Thuja orientalis* and *Frenela rhomboides* thrive best; some are 25 ft. high and 40 in. in girth. *Grevillea robusta*, 50 ft. high, 43 in. in girth; *Cedrela Toona*, 80 ft. high, 60 in. in girth; *Parkia Roxburghii*, 50 ft. high, 72 in. in girth; *Cassia grandis*, 40 ft. high, 45 in. in girth; *Spathodea campanulata*, 35 ft. high, 45 in. in girth; *Cedrela odorata*, 45 ft. high, 66 in. in girth; *Poinciana regia*, 30 ft. high, 30 in. in girth; *Cananga odorata*, 50 ft. high, 45 in. in girth; *Pithecolobium Saman*, 40 ft. high, 108 in. in girth; *Albizzia moluccana*, 60 ft. high, 108 in. in girth.

Hevea brasiliensis (Para rubber), seven years old is 40 ft. high and 30 in. round; *Swietenia grandifolia* (a mahogany), five years old, is 35 ft. high and 24 in. in girth. The Palms are mostly doing very well, and many will soon be yielding seed. The Giant bamboo is growing rapidly. The *Pimenta* also gives promise of doing well in this district.

Chrysobalanus Icaco (coco-plum of West Indies), the jamboo, the Malay apple, and other fruits, besides the oranges, &c., are doing well.

WEATHER.—A wet year on the whole, especially towards its close.

NOTES ON ECONOMIC AND OTHER PLANTS.

TEA.—The year has been favourable to this crop, the export one more being the largest on record. It exceeded 108 million pounds, an increase of almost 11 million pounds over 1895. The area under tea cultivation continues to increase, though more slowly than in previous years. The average price has been lower (about 83d per lb.) and exchange higher—two circumstances tending to check extension.

The tea plant seems admirably suited to the poor soil of Ceylon, and is also remarkably free from disease; this is probably in great part due to the tannin in the leaves. It will not do, however, to assume too great permanence for this immunity. Tea being a leaf-crop stands manuring well, and this is a great circumstance in its favour; the use of manure appears to be steadily increasing.

The tea industry would appear to have about reached its zenith, and a more critical period in its history seems likely to commence, demanding the attention of planters to scientific questions as to manuring, coarse or fine plucking, methods of manufacture, rotation of crops, and so on. The increased production, and the fact that the competition is now less with the hand made teas of China than with the factory teas of India, Java, &c., will gradually render haphazard cultivation and manufacture no longer profitable.

COFFEE.—The export of this product in 1896 fell, partly owing to bad crops, to little more than a third of that 1895.

The planting of Liberian coffee is apparently increasing slowly. Several kinds of Coffee are on trial in the Gardens (see section), but none show much promise of usefulness, being much attacked by leaf-disease. *Coffea stenophylla* in particular suffers from the disease. Great expectations have been aroused by the success, in Java, &c., of the hybrid between

Liberian and Arabian, and I hope to obtain this kind in 1897 for trial here.

CACAO.—The exports show a steady increase; those of 1896 exceed those of 1895 by about 4,000 cwt. Much anxiety was caused during the last quarter of the year by the rapid spread in Matale and Badulla Districts of a disease which has attacked the trees for some years past, increasing in destructiveness every year. The nature of the disease is at present unknown, but every effort will be made to discover its cause and to check its ravages.

The Nicaraguan cacaos referred to in the report for 1895 are now established, and some are growing well.

From the report for 1896 of Mr. Hart, Superintendent of the Royal Botanic Gardens, Trinidad, I quote the following paragraphs:—

“The ‘Old Red Dutch’ cacao sent at my request by the late Dr. H. Trimen, Director of the Ceylon Botanical Department, for comparison with our varieties, proves to be synonymous with the true Criollo cacao of Trinidad, having the same form and also the same white or light-coloured seeds. The Criollo variety has however almost disappeared from cultivation, being ousted by the more vigorous growing Forastero imported from the Mainland, with which it has evidently hybridized, if the numerous varieties or intermediate forms between the two kinds now to be seen growing in every plantation are to be taken into account. On estates where the Criollo form predominates the cacao produced is of the finest quality. The origin of the colour and form of Ceylon cacao has therefore been now fully ascertained.

“I would point out, however, the direct influence for good which a change of climate, or rather a change of seed from one climate to another brings to pass. The Forastero has practically ousted the Criollo of Trinidad. The Criollo introduced into Ceylon has done well there, while the Criollo of Nicaragua will as certainly fall before the recently introduced Forastero, as the same kind has been already displaced by it in Trinidad.

“Cultivators of all kinds will always find that great benefit arises from making a change of seed from one country to another or from one district to another.”

COCONUTS.—The export of oil continues to fall off, but that of most of the other coconut products shows an increase. The area of land planted in coconuts is also increasing.

RUBBER.—The tree of Para rubber (*Hevea brasiliensis*) which was tapped in 1894 was again tapped this year, yielding 3 lb. ½ oz. of dry rubber, or rather less than in 1894. The yield of this tree has been 27½ oz. in 1888, 42 oz. in 1890, 45 oz. in 1892, 51 oz. in 1894, 48½ oz. in 1896; total in nine years 13lb. 6 oz., or about 1½ lb per annum. The tree is now twenty-one years old, and should bear tapping every year. I desire to call special attention to this yield, for many persons entertain the most exaggerated ideas of the rubber-yielding capabilities of this and other trees. Of course a much larger yield can be obtained for one or two years, but it is at the sacrifice of the life of the tree. If the results of the tapping of this tree be taken as a basis, the yield of a rubber plantation after the tenth year (fifty trees to an acre) should be perhaps 100lb. of rubber per acre per year, worth about £12 or £13 in London. In comparing this with other products, it should be remembered that the labour cost of rubber is very small.

The cultivation of Para rubber seems likely to succeed in the low-lying wet districts of Ceylon. There seems little likelihood at present of any serious fall in the supply of rubber from wild sources, but the demand is increasing, and by the time that the private plantations in the East come into full bearing, it is quite probable that the easily accessible native sources will be becoming exhausted.

Little reliable information is at present available on the subject of rubber, and I am devoting what time I can spare from other duties to a series of experiments in cultivation and tapping of rubber at Henaragoda and Peradeniya (see above, section 3).

These were commenced at Henaratgoda in December chiefly on a plantation of eleven or twelve year-old trees, which being planted only 12 ft. apart, are now much too crowded. About 150 of them will be sacrificed in the course of the experiments, leaving more room for the remainder.

Several plants of Lagos rubber (*Kickxia africana*, Benth.) were received from Kew in 1896, but are not doing well. This species forms a stout tree, and is therefore suited to cultivation, but it will be a long time before seed is available in quantity.

CALUDOVICA PALMATA.—The attention of those interested in any of the planting or palm-leaf industries may be called to this plant, which grows readily at Peradeniya. From the leaves, cut into strips and bleached, are plaited the well-known and expensive Panama hats.

RHEA.—The floating of a powerful company to work the Gomess patents has once more attracted attention to this product, and a good deal of it has been planted in the Colony. It may be well to point out that it is still an open question how far it is likely to succeed here; large areas should not be planted without preliminary trial; only regions of uniform climate and with plentiful supplies of manure are well suited to the plant. It is my intention to open experimental plots of different varieties at some of our Gardens during 1897.

HIBISCUS TILIACEUS (Sinhalese, Beli-patta).—This local plant, abundant in swampy low-country land, especially near the coast, is worthy of attention as a fibre plant. The fibre of the inner bark is an excellent substitute for "Cuba bast," so much used by horticulturists. We are indebted to Mr. Charles Byrde, of Ambalangoda, for a sample bundle of the fibre, which has proved very useful for tying and general garden use. Mr. Byrde states that the fibre is easily prepared.

DIVI-DIVI.—This plant (*Cesalpinia coriaria*) is now doing well at Anuradhapura, and might be worth the attention of cultivators in the dry regions of the Island. There is a considerable import of the pods into Great Britain for tanning purposes.

COCA (**ERYTHROXYLON COCA.**—Some inquiry has been made for this plant during the year. At present prices its cultivation should be profitable, but any large production would probably reduce the price of the drug (cocaine) far more rapidly than was the case with quinine, there being much less use for cocaine than quinine.

CAMPHOR.—The batch of seeds received this year failed to germinate, and we shall not have any further plants for distribution for some time. 160 large plants from the old nursery at Hakgala were planted out above the plantation made last year, the plants have made a good start and some of them are now 5 ft. high.

VEGETABLES.—An attempt was made during the last few months of the year to form at each of the Gardens a vegetable garden containing all the native vegetables as well as those exotics which would be likely to succeed, and we have now a fairly good collection. Many tropical vegetables (and fruits) are promising subjects for horticultural work; if they were bred and selected as carefully as has been done with European vegetables, the result in time would probably be the obtaining of a number of first-rate table delicacies. There is a great opening in this direction for nurserymen, planters, and others in the tropics who cultivate upon a large scale. I hope to be able to do a little at times in these Gardens, but we have neither the space nor the skilled labour to do much.

CHOCCHO.—We received a few fruits of the white variety in February from the Botanic Gardens at Trinidad. Two plants are now doing well, and bearing a good crop. This variety will grow and crop in the low-country, whereas the green one does not do well below 2,000 ft. It is hoped, therefore, that it may prove a useful addition to our low-country vegetables.

An unfounded rumour is going about among the natives in the hill districts that this fruit is sometimes poisonous, and that its use produces rheumatism. There is no truth, so far as is known, in

these statements. Thousands of families in the West Indies feed on this vegetable throughout the season, and no ill effects have been observed.

LUCERNE.—The small plot at Hakgala has continued to crop well. At elevations above 4,000 ft., when once established and well cared for, this useful fodder plant will give good returns for many years.

FRUIT TREES AT HAKGALA.—Mr. Nock reports:—

As last year the crops of peaches, figs, and apples were destroyed by the burst of the south-west monsoon. Fruit trees of all sorts made rapid growth during the months of April and May, and judging from the wood then made any gardener would predict a good crop next year, but I fear it will be the same as the last few years. They do well until the end of the year; then comes the hot sun and dries up the buds and the most likely wood dies.

At the end of May several very good fruits of the Morella cherry ripened, and from June to September English blackberries fruited well. In June a few very fine fruit of a large round plum, known here as the Ooty plum, were gathered. They were of handsome shape and good colour; the largest weighed 1½ oz., and measured 6 inches in circumference one way. The three next largest weighed 5½ oz.

ORNAMENTAL PLANTS.—The new African plant, *Saint-paulia ionantha*, which forms a very pretty pot plant, is now well established and flowering freely. Mention may also be made of the success obtained with *Victoria regia* at Peradeniya. There are many pieces of water in the low-country where this magnificent plant should grow well. Its seeds are used in Brazil as a source of flour, and are known as *Mais del aqua*.

12.—HERBARIUM, MUSEUM, LIBRARY, AND LABORATORY.

HERBARIUM.—A considerable number of specimens have been mounted and laid in their proper places.

The draughtsman made eighteen finished drawings of Ceylon plants and two of foreign orchids, in addition to attending to the Herbarium and Library.

Mr. Nock made a collecting tour to the Horton plains district, and the draughtsman two tours, one to the Anuradhapura District and one to the neighbourhood of Ratnapura.

MUSEUM.—A few additions have been made during the year, but none of special importance.

LIBRARY.—This has been largely increased by the books presented to it by the late Dr. Trimen on his retirement. The available space in the Herbarium is now becoming overcrowded, and it will be necessary during the coming year to incorporate the room under the centre of the Herbarium (next to the dark room) for purposes of extension. I propose to cement the floors, &c., and construct a light staircase from the Herbarium, so that books and specimens may be carried under cover from one to the other. This addition will allow room for expansion for a few more years, after which it will be necessary to make an addition to the building. The roof of the Herbarium requires repairs, as also that of the Museum.

FLORA OF CEYLON.—As mentioned at the beginning of this report, this work was left unfinished at Dr. Trimen's death. Three of the four volumes are published, and the plates and a portion of the manuscript of vol. IV. are complete. Application has been made to the authorities of the Royal Gardens, Kew, for assistance in completing the work.

LABORATORY.—This has been occupied during ten months of the year by Mr. W. G. Freeman, of the Royal College of Science, London, who has been working at several problems in the anatomy and development of tropical plants. Several students and others from abroad are expected during 1897, and the available space will be taxed to the utmost. A separate building is required which would be more suitable for scientific work, and would enable the present small room to be used in extending the Museum. At present most botanical students and experts from Europe travel to Java for scientific work, but if suitable accommodation were provided here there is no doubt that many would be attracted to Ceylon.

The results of some of the work done in the laboratory by Mr. Keeble, who was here in 1894-95, have appeared in two papers—one, "On the Loranthaceæ of Ceylon" (our common parasites on trees) in the Transactions of the Linnean Society; and one "On the hanging Foliage of Tropical Trees" (as is well seen in *Amherstia*) in the "Annals of Botany," 1895.

13.—RECEIPTS FROM SALES.

The receipts of the year were:—Total Sales R3,560-78; Number of Purchasers 761.

The estimated value of plants and seed supplied gratis is:—Total R1,122-01.

14.—EXPENDITURE.

The total cost of the Department for the year 1896 has been:—Total R45,044-16.

JOHN C. WILLIAMS,

Peradeniya, April 20, 1897.

Director.

PLANTING NOTES.

THE INDIARUBBER-BUSINESS.—Owing to the increase in the cycle industry the consumption of indiarubber has increased to such an extent—says the *Chemist and Druggist*, that it is estimated that last year alone over one hundred millions of trees were destroyed for the purpose of supplying the requirements of the markets. At present very few attempts at planting indiarubber trees are made anywhere.

THE FAUNA OF BRITISH INDIA, including Ceylon and Burma, published under the authority of the Secretary of State for India in Council. Edited by W. T. Blanford.—The mail brings us:—Hymenoptera.—Vol. I. Wasps and Bees. By Lieut. Colonel C. T. Bingham. It is a handsome book of 576 pages with full index. The London publishers are Messrs. Taylor and Francis, Red Lion Court, Fleet Street. Calcutta: Thacker, Spink, & Co. Bombay: Thacker & Co., Limited. The whole series will be invaluable to naturalists.

CEYLON TEA.—India and Ceylon have taken the position of the finest tea growing districts in the world, and there is little probability that they will ever be ousted from it. Ceylon especially is looked upon with favour by both growers and dealers, whilst the tea to which it gives its name stands unrivalled in the estimation of the consumer. With a constantly increasing demand, and that, too, for the finest qualities, the position and prospect of the tea planters is by no means unfavourable, and the estates which come before the public as the property of joint stock companies offer opportunities for investments which are not to be despised in these days of redundant capital and low rate of interest.—*Financial paper.*

PRECIOUS STONES.—We direct attention to a serious letter on this subject in a Madras paper, reproduced on another page. The writer seems to know a good deal about precious stones; but is he aware that the simplest (and yet one of the best) tests applied to gems by M. Nordenskjöld—the Norwegian who first got round Asia by Behring's Straits—whose special forte was Mineralogy, was by comparing the brightness of the stone in artificial and in sun light. The brilliancy ought to be as great under gas, candle or match as in the sunlight. M. Nordenskjöld examined all the gems in the Colombo Museum, in sunlight and then by striking a match in a dark corner. Ceylon may be said to have a monopoly of cat's-eyes, Alexandrites, and of the finest sapphires. Siam and Burma compete in rubies.

RUBBER SUPPLY.—A Zanzibar contemporary, in the last issue received, devotes a large proportion of its space to a consideration of the rubber supply of East Africa. India-rubber is reported to be very scarce just now, and the sources of supply to be diminishing. Such, however, is not the case, for although the West Indian rubber supply is falling, there is an abundance in tropical Africa. From ocean to ocean across Equatorial Africa, we are told, a belt of more or less richly yielding rubber trees is to be found. Negroes who discovered the value of the trees which the white man was tapping, began lopping them down, and thousands of dead trunks are now to be found disfiguring the forests. Whether the yield is increased or not by cultivation of the tree is a disputed point. Cultivated rubber may prove to be cheaper and in the better long run than the wild product by reason of the skill imported into the industry. Only the richest varieties of tree or vine would be grown, the collection and treatment of the juice would be conducted in a less wasteful manner, and there would be no adulteration.—*Indian and Eastern Engineer.*

SHANGHAI CROTON-SEED.—At the last drug-sales there was shown a sample of croton-seeds from Shanghai which failed to find a buyer, presumably on account of the difference in appearance from the usual Ceylon seeds. The sample in question was of a dirty dark brown colour, partly covered with a lighter brown scale-like covering. When cracked the seeds were found to be white, but showed some tendency to shrivelling, indicating a want of freshness. Considering that the *Croton Tiglium*, which furnishes the croton-seeds of commerce, has such a wide distribution from China and the Malay Islands to Malacca, Burma, Bengal, Assam, and Ceylon, it is surprising that regular supplies from most of these countries do not find their way to the London market. The seeds, however, are sometimes imported into India from China, via Singapore. They are regarded by the Chinese as extremely poisonous, and Porter Smith says, "A single decorticated seed was formerly prescribed in dysentery and diarrhoea as a revulsive remedy" by the Chinese. The seeds in question were quite genuine.—*Chemist and Druggist*, April 17.

A DECAYING INDUSTRY.—The possible disappearance of the art of dyeing in India is pointed out in an able monograph prepared by Mr. N. N. Banerjee under the auspices of the Bengal Government. The number of professional dyers in India is fast diminishing. Aniline dyes and cheap European goods are killing their trade. They are being compelled to turn their attention to new handicrafts, just as French competition and the vagaries of fashion caused the ribbon makers of Coventry to seek a new livelihood in the manufacture of bicycles. Aniline dyes have made every man his own dyer. Formerly, the complicated processes by which indigenous dyes are prepared made the dyer a specialist. Nowadays, anybody can dissolve the chemical powders sent out from Europe, and colour his own clothes. The aniline dyes are more brilliant, and, to the native, they have the superlative merit of cheapness. They are not so fast, and they lack the delicacy of colour, which, judging by the specimens annexed to the monograph, distinguish the Indian dyes. But their very gaudiness makes them more popular, and so the fate of the native dyer is sealed. Silk-dyeing, cotton-dyeing, and carpet-dyeing—all are declining. The fault, it should be added, is to some extent due to the conservatism of the native dyers themselves. They persistently adhere to their crude methods of preparing their dyes, and show a lamentable lack of ingenuity in preparing new designs.—*Pioneer*, May 22.

PLANTING PROSPECTS IN BRITISH NORTH BORNEO :

ESTIMATE FOR LIBERIAN COFFEE.

As we mentioned already Mr. Henry Walker, Commissioner of Lands, British North Borneo, who arrived at Colombo recently by the German mail steamer "Preussen," made a stay of about three weeks in the island, principally for the purpose of affording information to planting capitalists regarding the prospects in that settlement. Soon after his arrival, Mr. Walker left for Kurung-gala on a visit to friends, but before he took his departure he kindly favoured us with a few notes which we think will be read with interest by our readers. He mentioned that some very important enterprises are now being energetically pushed in North Borneo by monied Companies or Syndicates, notably the Railway (by the Government) from the Coast to the, as yet, unopened interior. With regard to the tobacco enterprise he said that the crop of 1896 now going to Europe will be 12,000 bales of 188 lb. each and the prices realized this year in Amsterdam, are 50 per cent higher than last year (which were considered high). The timber trade with China is increasing and the Bombay-Burmah Trading Company propose to lay down a large saw mill. As the wood there is suitable for tea boxes a large trade may be done with Ceylon. Petroleum oil is being sought for and the Bombay-Burmah Trading Company lately sent 100 tons of boring plant to North Borneo. Oil is known to exist at two places and it is hoped a large quantity may be found to exist. The exports of coal from Labuan and Bremer Bay are increasing—say 4,000 to 6,000 tons per month. It is used by the P. & O. Company who lately made a contract for 10,000 tons—and it is understood they are satisfied. From a circular prepared by Mr. Walker we are permitted to make the following extracts :—

We have a well divided rainfall, and, consequently, although it is heavy, say from 70 to 120 inches per annum, the effects are not so disastrous as in those tropical countries where the rainfall is limited to a few months of the year and the daily fall is so great as to wash away all the humus, and, further, our rocks, including lime-stones, serpentines and conglomerates, are naturally rich in substances suitable to vegetation, and, when evaded, afford a suitable soil for tea, coffee, sugar, cinchona, gambier, coconuts, &c., all of which (except cinchona) have been tried with success either experimentally or on a large scale, and as our hill lands run up to a height of over 13,000 feet, we can offer the intending planter the prospect of making a home in a cool and invigorating climate.

I believe we now offer better prospects of financial success than any other tropical country. At present we are willing to make free grants of 500 acres on a 999 years' lease to encourage the planting of certain products, provided that the intending investor has £2,000 capital and will make a *bona fide* commencement to bring such land under cultivation within 18 months from the date of the selection of the land and that he will bring one-third of the 500 acres under cultivation within 12 years from the date of the agreement for a lease. Should he fail to cultivate one-third of the 500 acres he will be only entitled to retain 2 acres of jungle for each acre cultivated; but if he desires to retain the balance of the 500 acres he can do so by paying 20 cents rent per acre or purchase such balance at three dollars per acre.

The Currency in use is British North Borneo in the Mexican dollar, which since 1894 has fluctuated in value between 1/11² and 2/1². The average rate of pay on the estates, including the Mandore (cangany) is between 27 to 29 cents a day. The coolies employed are Javanese, with advances and Malays

or varieties of the Malay race, with or without advances as the case may be. On Ulanpakad Estate, now being opened by Mr. E. R. Walker (late of Le Vallon Estate) the coolies employed are obtained on the spot, and the advances outstanding at the end of each month are under two dollars a head, and at Toritipan Estate with a force of over 200 coolies of mixed nationalities, the total advances are usually under \$1,000 or less than \$5, a head, which amount is not guaranteed by the Mandore, but is a debt, due by each individual cooly. The Javanese and Malays from Singapore usually sign to work a year and receive \$12, or even \$18 ahead repayable in equal monthly instalments: the locally engaged coolies work on a verbal agreement terminable by a month's notice, and receive two or perhaps three dollars advance, which is really a cash advance to obtain food, and is deducted at the end of the month if the Manager thinks fit.

Food supplies are paid for by the coolies, or each week a chit is granted by the Manager for a small sum which is accepted by authorized shops, where food is supplied at fixed rates, of which a scale in English, Malay and Chinese is hung up on the door of the shop. The transport acquired by the Estate is done by the shopman.

In 1895 I constructed a trial path from the west coast to the interior, where there is a large native population, and since I left (in May, 1896) a Railway (metre gauge) has been taken in hand, following much the same line of country. The Railway line when finished will be about 52 miles long with the upper terminus (altitude 600 feet) at the foot of a range of hills running up to 3,400 feet with good soil and well watered. The Railway works now afford employment to a large number of Chinese and natives, and, when completed, a large body of well-disciplined labourers will be available for the planting industry. A planter can now obtain work-people—men, women and children—near the line of Railway. He must, however, be able to speak Malay, a language easily acquired, and he must follow the customs of the country; if he cannot accustom himself to these he had better not come.

I give below an estimate of the cost of opening 100 acres of Liberian Coffee which works out (at the end of the third year) at something less than £15 sterling per acre. The figures were given me by a Coffee Planter in British North Borneo, and are based on rates and wages as now paid. I have appended a few remarks on the items showing where a managing proprietor may economise, and a little examination of the estimate will show that £12 per acre should suffice and that a second 100 acres could be planted for about £10 an acre. I should also mention the fact that the expenditure is becoming less and less each year.

Estimate of cost (in dollars) of opening 100 acres of Liberian Coffee in British North Borneo.

Present rate of Exchange 2s. per dollar		
Superintendence, say 12 months at \$ 150		
per month	1,800	
Felling 100 acres at \$ 2.50	250	
Piling and burning „ 3.50	350	
Lining „ 1.00	100	
Holing 43,500 holes 2 ft. by 1 ft. 6 in. (10 ft. by 10 ft.) at 1 cent	435	652
Filling and planting at 1½ cts. per hole ..	75	
Shading at 75 „ per acre	100	
Supplying		
Nurseries and seed—N.B.—The seed should be obtained from a high estate in estate in Ceylon or India	300	
Weeding 6 months at 90 cents per acre per month	540	
Roads and Drains	1,000	
Lines, 2 sets	150	
Bungalow	500	
Tools	250	
Contingencies	500	

Cost at end of 1st year .. \$ 7,002

Superintendence	1,800
Supplying	100
Nurseries	100
Weeding at 90 cents per acre per month	1,080
Roads and Drains	200
Buildings	100
Tools	100
Contingencies	250
<hr/>	
Cost during the 2nd year	\$ 3,730
Ditto 3rd year exclusive \$ 3,730
of crop expenditure \$ 3,730
<hr/>	

Total cost at end of 3rd year .. \$ 14,462

In the foregoing estimate the cost of weeding has been taken at a safe figure. Mr. E. R. Walker opened 36 acres in 1896, and his weeding for the five wet months, October 1896 to February 1897, averaged 80 cents per acre per month and the older coffee on Taritpan Estate costs 55 cents on monthly contract. The item superintendence is a heavy one, but that would be less *per acre* as soon as a larger acreage is taken in hand. As the actual cost of living is not more than one dollar a day for food, the intending planter may gauge his own personal expenditure on drinks, clothes, etc. The other items are based on the present cost of works in British North Borneo.

The yield of crop in the 3rd and 4th year should pay for the crop buildings and machinery say a total of £200 to £300. Large stores are not necessary provided a small hot air drying shed be erected, in which the parchment can be dried in about 8 hours and be packed in bags and despatched the same day. The 5th year should give 5 cwt. and when the coffee is 6 years old the yield of coffee may be expected to be 7 cwt. per acre without manure, but with manure 10 cwt. or even more may be expected.

The expenditure on the estate on a crop of 7 cwt per acre should be less than thirteen dollars per cwt. and the London expenses including freight are nearly 9 shillings per cwt., say at present exchange a total cost of about 35 shillings per cwt. As I have previously stated, we find that the estate expenditure is becoming less each year, according as the labourer becomes more skilled.

HIGHLAND TEA COMPANY OF CEYLON, LIMITED.

The first annual ordinary meeting of this company was held on Wednesday, at the office of the company, 16, Philpot Lane, E. C., Sir George A. Pilkington (chairman of the board) presiding.

Mr. J. F. ANDERSON (of Messrs. Lyall Andersen & Co., agents and secretaries), having read the notice convening the meeting,

The CHAIRMAN said: I have now pleasure in moving that the report as presented to the shareholders be received and adopted. The report as produced by the secretaries is very complete and concisely put together, and the figures are so extremely clear that very little need be said. The proposed dividend of 7 per cent. is in these days, you will admit, a very satisfactory one, and you will see that we are writing off one-half of the preliminary expenses, and carrying forward £404 odd to the next year. Although 7 per cent. is a satisfactory return nowadays, I am bound to say we, as directors, are not by any means satisfied with it. We hope for very much better things. I don't think the estate this year has done itself justice. Of course, against all estates there has been the unfortunate rise in the value of the rupee, which we think, however, will to some extent be done away with again before the end of another twelve months. But apart from this, the estates have not come up to expectation. They are amongst the finest estates in the island; Glenorchy has without exception the finest tea bushes of any I have ever seen in my life. We expect better results both from the average crop and the prices realized. The result of the past

year may be explained to some extent by the fact that the manager has been away from the estate on leave of absence home, and we know that nearly every tea district has the peculiarity that the manager who has lived a long time on the estate does better than a successor from another part of the island, who will not understand the particular requirements of the bushes as well as the old resident. We reasonably hope for much better things another year. There is little more to be said, but whatever you wish to hear on the subject I shall be very glad to answer you, as I have within a comparatively recent time visited the estates, and I am, therefore, aware of their present condition. The only item of any importance outside the ordinary run of a balance-sheet and report is the fact that you have to fix the remuneration of the directors. That is a matter which we must leave entirely in your hands; you are aware that under the articles of association it is to be fixed at the first annual meeting. I have pleasure in moving, "That the report as presented to the shareholders be received and adopted."

Mr. G. G. ANDERSON seconded the motion, which was carried unanimously.

The CHAIRMAN then moved, "That a final dividend of 3 per cent. free of income tax, making in all 7 per cent. for the year be declared payable forthwith."

This was seconded by Mr. ANDERSON and carried.

Mr. ANDERSON proposed and Mr. C. J. SCOTT seconded the re-election of Sir George Pilkington as a director—Carried.

Mr. E. J. MARSHALL proposed and Mr. W. D. CAMPBELL seconded that Messrs. Cape & Dalgleish be re-appointed auditors to the company.—Carried.

Mr. DONALD ANDREW proposed, "That the directors shall receive for their services a sum at the rate of £200 per annum until the company earns a profit of 15 per cent., and then at the rate of £300 per annum." He observed that the labourer was worthy of his hire, and he was sure his motion would be received with hearty approval by all the shareholders. The affairs of the company were in capable hands, which in itself was enough to ensure success.

Mr. A. LESLIE seconded the motion, remarking that the remuneration proposed was very reasonable. He admired the chairman's frank statement of the position of affairs, and only hoped that his anticipations would be verified.

The motion was carried.

The CHAIRMAN next proposed that a vote of thanks be accorded to the Ceylon and London staffs for the efficient working of the company's property and business. He said they were well satisfied with their representatives in Ceylon. Mr. Nicol, upon Glenorchy, was an old planter, and Mr. Fraser, on Chrysler's Farm, was also one of the oldest planters in the island. In both of them they had every reason to show perfect confidence. The staff at home had worked laboriously and honestly in the interests of the company.

Mr. SCOTT seconded the motion, which was carried.

A vote of thanks was passed to the chairman and directors of the company on the motion of Mr. ANDREW, seconded by Mr. LESLIE.

The CHAIRMAN, in acknowledging the compliment, said the directors would do all they could to develop what he believed to be one of the finest and most valuable properties in the island.—*The Investors' Guardian*, May 1.

SCOTCH CEYLON TEA COMPANY, LIMITED.

Directors:—H. I. Forbes, Chairman, R. W. Forbes, Donald Andrew. Managing Director: H. L. Forbes. Manager in Ceylon: David Kerr. Secretaries: Lyall, Anderson & Co.

Report of the Board of Directors, to be presented to the Shareholders at their eighth annual ordinary meeting, to be held at the offices of the Company on Thursday, 13th May, 1897, at 12 noon.

The Directors have pleasure in submitting to the Shareholders the accounts and Balance-sheet for the year ending 31st December, 1896.

The net profits for the year amount to £8,976 15s. 6d. to which has to be added £852 13s. 9d. brought forward from

	£	s	d.
last Accounts, giving a total sum to be dealt with of ..	9,829	9	3
An interim dividend on the Ordinary Shares of 5 per cent (free of Income Tax) paid in September, 1896, absorbed ..	2,050	0	0
Dividends on the 7 per cent Preference Shares have also been paid amounting to ..	630	0	0
It is now proposed to pay a final dividend on the Ordinary Shares of 10 per cent (free of Income Tax), making 15 per cent for the year ..	4,100	0	0
To add to Reserve Fund (raising it to £7,000) ..	1,000	0	0
And to write off for depreciation on Buildings and Machinery ..	797	2	0
	8,577	2	0

Leaving a balance to carry forward to next account of £1,252 7 3

Satisfactory as the above results are, they would have been even more so, but for the higher rate of exchange current during the latter part of the year. The Buildings and Machinery on the Company's Estates are in efficient order, but the Directors think it advisable to continue the policy of writing down their cost, and the amount appropriated for this purpose represents 10 per cent on their value as it stands in the books on 31st December.

The total crop secured from the Company's properties during the year amounted to 720,200 lb. being 48,200 lb. over the estimate and 52,151 lb. more than the previous year's out-turn, which the Directors consider a satisfactory advance. In addition to the foregoing, 170,764 lb. of tea were manufactured for others, giving a total output from the Comptny's Factories for the year of 890,964 lb. made tea. The average yield per bearing acre was 422 lb. against 433 lb. for 1895, the difference being due to the fact that young tea on Lonach estate is now classed as "bearing" although it has not yet attained full maturity. The average price realized for the tea sold in the London market was 8'860d. per lb., shewing a fractional reduction from the figures given in last report. The total acreage of the Company's estates remains unaltered at 1,963 acres, including 1,544 acres in full bearing, 163 acres in partial bearing, and 13 acres plauted during the year, or a total of 1,720 acres under tea cultivation.

The Ceylon manager, Mr. Kerr, who resumed charge of the Company's affairs in Ceylon on 1st February, reports that the estates are all in excellent order, and his estimates for the current year point to a continuance of satisfactory returns. During Mr. Kerr's furlough Mr. G. M. Ballardie kindly undertook the temporary management in Ceylon, and the thanks of the Board are due to that gentleman for the able manner in which the Company's interests were looked after by him during his tenure of the post. The Directors have also much pleasure in again expressing their appreciation of the services of the Company's staff, both in Ceylon and London.

In accordance with the Article of Association, Mr. H. L. Forbes retires from the Board, and, being eligible, offers himself for re-election. The Shareholders will also be invited to express their approval of the appointment of Mr. George Gray Anderson to a seat on the Board. As provided in Company's Articles a Resolution to carry this into

effect will be submitted at the Meeting. Mr. J. B. Laurie, C.A., offers himself for re-election as Auditor, an appointment which the Shareholders will be asked to confirm.

THE TEA ENTERPRISE IN TRAVANCORE,

CEYLON MEN IN THE DISTRICT.

"Mr. Forbes Laurie's Company own a lot of places," said Mr. Deane, in reply to another question. "Mr. Buxton Laurie, who is well-known in Ceylon, is in charge of the group, and he has another Ceylon man, Mr. Slowcock, and others to assist him. They have 220 acres of new clearings—the best-opened land I saw in the district. It has been exceedingly well done. Amongst others who are known in Ceylon there is Mr. Imray; and he has lately imported two planters from Ceylon to work his places. Mr. Wood, formerly of St. Andrew's in Ceylon, is P. D. on the Mount and Mr. Plaice, who was also on St. Andrew's, is on Muujamally, and Mr. Imray told me they were endeavouring to get two more men from Ceylon, so that the district is gradually filling up. No, I have so far not had a Ceylon man on the Stagbrook group, but I have been looking out for one, and now have practically concluded arrangements with a planter who will suit me, and who will relieve Mr. Holden, who was very kindly lent me temporarily."

TEA AND COFFEE.

"The tea is magnificent, and is doing splendidly, and I saw a very fine field of coffee belonging to Mr. Goldie, also an old Ceylon planter. He has a capital field of coffee at a place called Pakanam. It is under grevillea shade, and looks as it would give five or six cwts. an acre. It is coffee Arabica, and it is about 6 years old, for it was just being planted when I was last in Travancore. I think Mr. Goldie got 30 tons off it last year, which was not bad for an estate of 150 acres. One hears a lot of the difficulties of transport, and the consequent enhancement of cost, but even now you can get tea put on board ship for 12 annas a chest. The average cost of tea as far as I could make out was 3½ annas—that was the average on all the estates in Peernamaad, f.o.b., and it is very reasonable. As regards the question of transport, I may say that I was told that the Travancore Government have voted three lakhs for a road from Kotium to Monde-Kaiam, at the foot of the ghaut, a distance of about 50 miles. There is a cart-road there at present, but this money had to be voted for improving it, and the Government advertised for local tenders, but had got none by the time I left. As regards the tea itself, to prove what can be done with a properly-equipped factory, Mr. Buxton Laurie shewed me his accounts for the past year, and in every month but one he had beaten the Ceylon average, and in the one month he failed to do so he was only about a farthing below. I like the tea produced there very much; it is a good high grown tea and has a very lilly flavour."

A BOOM IN FACTORIES.

"Where Travancore has hitherto been backward has been in not having proper factories. Until lately there was hadly a decent factory in the district, but Mr. Imray has a magnificent factory now being built; Mr. Forbes Laurie has a nice factory; and Mr. Ackworth, Chairman of the Planters' Association, has a very good one, and he got very good prices last year. He has also some of the finest seed-bearers I have ever seen, and anyone wanting seed had better get it through him. He has 60 acres of seed-bearers—once removed indigneous, and I have ordered some from him. He is fully booked for this year, now, but next year he expects to have 400 mannds, and I advise anyone to book with him as the price is reasonable, and the seed excellent. My factory on Stagbrook has hitherto had only hand power, but I have just ordered a lot of machinery from Davidson's for the place. Still, with the hand machinery I made 120,000 lbs. of tea this year! One thing I may tell you in this connection. It is the exception to find a factory without on oil-engine. The Tangey and the Dickson-Ackroyd patterns being most popular, and in no case have I heard a complaint about them, while they work easily and inexpensively. I have ordered one myself.—Mr. H. D. Deane to "Local Times."

SCIENTIFIC AGRICULTURE AGAIN:
THE WEST INDIES V.S. CEYLON.

It is somewhat ludicrous to note the progress made by tiny insignificant West Indian islands in calling in science to the aid of their agriculture and planters, as compared with the do-nothingness of the Ceylon Government. The Ceylon Civil authorities seem to content themselves with showing a budget worthy of the first of Crown Colonies, due mainly to a Customs tariff,—which enlightened administrators ought to be ashamed of,—and to a Railway income with which no single Civil Servant has anything to do. The Ceylon Government got one of the most direct and terrible lessons during 1878-83 ever served out to an administrative body dependent mainly on Agriculture; but how has it been taken and the experience so gained turned to practical use? The only practical step taken in all the years of prosperity which have accompanied the rise of tea, has been the establishment of the Agricultural School—now threatened with abolition! One would think that, after the extinction of our coffee through the operation, first, of an insignificant fungus, and afterwards of a scale insect in green-bug, that one of the first steps taken by a Ceylon Executive would be the establishment of a Scientific Board of Experts to watch over the new staple tea—on which local prosperity so largely depends—as well as over our palm and other branches of agriculture. Not a bit of it. The salary—even temporarily—of an Entomologist was grudging and absolutely refused by Sir Arthur Havelock who, however, took care to avoid fulfilling his distinct promise to cut down the Revenue Civil Establishments after a large part of their work was abolished with the disappearance of the paddy rents. Everything in Ceylon, in fact, has been left for the planter agriculturist to find out for himself, save in so far as the Royal Botanic Gardens, the Director and his lieutenants could render aid. Anything like scientific experiments at the instance of the Government, for the benefit of planters or farmers, Europeans or native, has never entered into the local official mind.

Now let us turn for a contrast to the Far West. Antigua is one of the Leeward Islands with an area of 108 square miles, population under 40,000; total trade under half-a-million sterling and revenue under £55,000—and yet it can have what is denied to Ceylon, a colony nearly as large as Ireland, and the first in revenue, trade, and importance of all Crown Colonies. A recent mail brought us from Antigua:—

“Report of the results obtained on the experimental fields at Skerrett’s School, 1896, by Francis Watts, F.I.C., Assoc. Mason Coll., Government Analytical Chemist, and F. R. Shepherd, Superintendent, Skerrett’s School.”

And we have here, in the course of some eight pages of letterpress and as many of tables, most careful and elaborate experiments for the benefit of the local sugar planters after the pattern set by Sir John Lawes and Mr. Gilbert for English Agriculturists. Everything is scientifically arranged, and the results for a whole series of “experimental plots” are given in a way that the simplest planter cannot fail to understand. Now this is only one way in which science could render help to our Agriculture and Planting. But how much money might have been saved, and

how much useful knowledge gained, had Ceylon its two officers set apart for such work; while an Entomologist and Fungologist, also of the same Scientific Board, were hard at work in the other directions in which so much can be done for our cacao, tea and coconut planters.

We must sincerely trust that Governor Ridgeway will see his way to give the colony a Scientific-Agricultural Board,—two or three new officers to be associated with the Director of the Botanic Gardens, the Conservator of Forests, and Mr. E. E. Green among others—and if a model is wanted, it can be found in Java, if not in the West Indian Islands; while as to the funds, if there is any scarcity, let them be found by amalgamating—doubling-up—some of the provincial agencies. An Assistant Agency in place of a full-blown Agency at Ratnapura, Badulla, Anuradhapura and even Kurunegala would not be such a revolutionary matter; and certainly the difference, administratively, would not be observed by the people concerned; while, on the other hand, the absolute direct benefit from the Board of Science and Agriculture—or whatever it might be called—could not fail to make itself felt, almost from the very beginning of its work. Has Sir West Ridgeway realised yet that, in coconuts alone, there is room, through improved cultivation among the natives, for nearly doubling the production of one of the most important local food as well as export products of the island; and has it not been made plain that our cacao planters have been working in the dark for many years against a dire enemy; while who can say how long it may be before tea is afflicted? Prevention is better than cure—to learn about existing, if latent, cucurbs beforehand is far more advisable than to study life histories after destruction has set in.

Here is an indication of what the Government of India is doing in a paragraph just received through the *Pioneer*:—

“CHEMISTRY AND AGRICULTURE.—It is understood that the abolition of the appointment of Agricultural Chemist to the Government of India next November, when Dr. Leather’s term of office expires, will clear the way for the appointment of a stronger scientific staff for other economic investigations under the Revenue and Agricultural Department experts. The investigation of such troubles as wheat rust and insect blights, in particular, is likely to be undertaken, but details are still very vague. The principle likely to be adopted, however, is broadly to confine the Government paid scientific help for the present to such industries as wheat culture, which are in the hands of those too poor to pay for the employment of scientists, industries like tea and indigo being left help themselves, on the ground that they are well able to do so.—*Civil and Military Gazette*.” Insect blights in Ceylon deserve fully as much attention as in India and they ought to be thoroughly investigated.

The above was in type before we received the very practical and instructive Report for 1896 of the Director of Ceylon Botanic Gardens. Mr. Willis recognises the need for an Analytical Chemist, and we feel sure he would be glad of expert aid in several directions.

DR. PAUL TAUBERT has died of yellow fever during his exploration of the little-known territory Amazonas, in MANAOS. His death occurred on New Year’s Day last.—*Gardeners’ Chronicle*.

THE CREEPER.

(BY A CEYLON TEA PLANTER.)

The rise and progress of the tea industry in Ceylon has been accompanied by the appearance and rapid multiplication of the "Creepers" in all his varieties. The Creeper is not an insect, nor reptile, nor a plant, nor anything at all interesting from a naturalist's point of view. Although he may be said to live upon tea, tea is not his only food, nor, excepting a few rare instances, his only drink. As a rule, he is a good, healthy specimen of British youth. Various causes, more or less connected with a distaste or incapacity for arduous and prolonged study have prevented him from entering the Army or any of the professions, and his parents having no connection with "business," and lacking the means to maintain him in idleness, are at their wits' end to know what to do with him. In these circumstances, it is very odd if some member or friend of the family does not suggest Ceylon as a happy hunting ground for needy British youth. "Fine climate, beautiful scenery, and all that sort of thing you know. Tea enterprise in a most flourishing state, and sure to afford a great opening. Planter's life very jolly and easy. Out of doors all day, and excellent sport to be had." Inquiries are set on foot, and it soon appears that there is no difficulty whatever about learning to plant tea. There are plenty of planters, but owners and superintendents, who are glad enough to add to their incomes by pocketing premiums, and, in exchange, letting young men do the hard work of their estates for them. They do not put it in that way, of course. They say that, for a consideration of, say, £100 (the amount of premium varies in direct proportion to the calmness and assurance of the individual planter with whom the business is negotiated), they are prepared to teach a young man his work, and that if he is steady and industrious they will no doubt be able to find a billet for him in due course. They allude to certain youths who have learned planting from them, and who have done very well, and they carefully refrain from hinting that such cases are at all exceptional. This seems to be very promising and satisfactory, and as the young man is beginning to be rather troublesome at home, the preliminaries are concluded, his "kit" is purchased, his passage, taken, and he is sent out to Ceylon to make his fortune in tea.

If his friends have arranged for him to begin his career on a good estate in one of the populous districts lying 2,000 feet or more above the sea level he may find the life pleasant enough, and if the superintendent has a natural aptitude for the training of youth, and takes an interest in the Creepers under him, he may learn his work very quickly. Estates and superintendents, however, vary considerably in the facilities they afford either for the enjoyment of life or the acquisition of knowledge. The Creeper must rise very early in the morning, in order to have time for his early tea, for he must muster the coolies, both men and women, at six o'clock, and send them off to the different parts of the estate where their work lies. All day, with the exception of an interval at noon for tub and breakfast, he is engaged in visits of inspection to the various working parties, weighing the leaf brought in by the pluckers, and preparing returns and reports for the information of the superintendent. As most estates are situated on steep hillsides, these daily rounds of inspection entail some pretty severe exercise, and conduce to the preservation of hard condition. Any youth with ordinary intelligence and powers of observation can soon learn the work connected with the Creeper's daily routine, but in order to qualify himself for a superintendent's billet he must master all the processes that are carried on in the factory down by the cart road, where the big water wheel turns unceasingly, and the tea undergoes a course of preparation which changes each fresh green leaf into the shrivelled and tightly-rolled particle with which the consumer is familiar. The work of the factory is superintended by a native or burgher (half-caste) tea-maker, and a Creeper is

usually allowed to acquire as much, or as little, knowledge of its details as he may feel inclined to pick up. If he is wise he will learn not only to judge the value of the ultimate result, but also to detect the true cause of any shortcomings, for the tea maker will attribute them to the poor quality of the green leaf, or the system of plucking, or defective machinery—to anything, in fact, rather than want of skill or care on his own part.

It may be imagined that a Creeper who has made himself thoroughly conversant with all the branches of estate work, both on the land and in the factory, is thereby qualified to take charge of an estate himself. This, however, is by no means the case. A man may be competent in every other way, and yet be unfit to be a superintendent, owing to his inability to manage coolies. A review of the labour question in Ceylon does not fall within the scope of this article. It is sufficient to remark that your coolie is daily becoming more and more independent, and that he is gradually awaking to the knowledge of the means by which he may take full advantage of the beneficence of the British rule (from his own point of view) in respect of legislation and the administration of justice. To keep the labour force on an estate contented and efficient requires a rare combination of tact and firmness, and a thorough comprehension of the motives by which a coolie is principally actuated, and the methods by which he may be persuaded that he can best secure his own welfare by serving his employer faithfully. Nothing is more useful in the management of coolies than a good knowledge of their language (Tamil). Many men think that they know enough Tamil when they can make a few brief orders intelligible to their own coolies, though they may be unable to understand more than half of what the coolies say to them, and though strange coolies receive their remarks with the stare and grunt which are so very exasperating. A Creeper should not rest satisfied till he can converse freely with any Tamil, or even with a Sinhalese who speaks Tamil, on any ordinary topic. So much for the Creeper's work, now for his prospects.

The chances of making money in tea grow less year by year. Fine fortunes have certainly been made with it, and the writer has known men who, by investing a few hundred pounds, have found themselves after ten years, or even less, in possession of properties bringing in a clear profit, of between £1,500 and £2,000 a year. At the present time, however, land has risen so enormously as to greatly reduce the possibility of making large profits. The salaries of superintendents, also, owing to the ease with which a knowledge of tea planting can be acquired, and the rush of Creepers, tend to become less and less. If a Creeper can, after a year or two of probation, secure a billet worth 200 rupees a month, he will have done well, and it may be years before he can get anything better. As a rule, estates which belong to non-resident proprietors or to companies are not left entirely in the hands of superintendents, but are inspected periodically by planters of ability and experience called visiting agents. The appointment of visiting agent to a large group of estates is, of course a valuable one, but such posts can, naturally only be obtained by a favoured few, and are hardly likely to fall to the lot of the average "Creeper."—*Globe*, May 5.

PRODUCE AND PLANTING NOTES.

PERU AND THE TEA TRADE.—As those interested in India and Ceylon tea are always on the look out for new markets, a forthcoming exhibition in Lima, Peru, should attract attention. There is some scope in South America for pushing the sale of tea. That the present Government of Peru is anxious to do all in its power to foster and extend the trade of the country is shown by its action in promoting a permanent Industrial Exhibition, which is to be opened at Lima this summer. In order to ensure the success of the undertaking, a section of the Exhibition Palace at Lima has been set aside specially for it, while the whole of the arrangements are in the hands of the Minister of Public Works. Goods

and exhibits from all parts of the world can be shown, and manufacturers in Great Britain are to be invited to send goods, the Government undertaking to admit free for six months all exhibits. Should any of our readers desire to be represented they should communicate at once with Mr. K. B. Crowe, Consul-General for Peru, 13, King Street, Liverpool.

THE PLANTING INDUSTRIES OF MEXICO.—At a recent meeting of the Mexican shareholders of the Mexican Coffee Trading and Planting Company it was mentioned that there are already 1,500,000 coffee plants in the company's nurseries, which will be ready for transplanting this year; 60,000 one year and a half old trees have been planted, and are in good condition. The American Consul at the City of Mexico says, "That, striking as are the facts with regard to the increase of the cultivation of coffee and the growth in the United States of a great appreciation of the Mexican berry and its sterling qualities, these can be paralleled in many points by the development of Mexican tobacco." Although France has not profited commercially by this increase, it is only simple justice to say that it is due very largely to Frenchmen and to the exiles from Cuba whom they employed. "In a word," says Consul Crittenden, "Mexico is not only one of the coming coffee countries, but is also a coming tobacco country. Mexico seems to be destined to wear the mantle of Habana in tobacco production, and once secured it is safe to predict that it will never pass away, for the soil of the tobacco region is so deep as to be practically inexhaustible, being from 8 ft. to 20 ft. in depth, and in some places even 30 ft. Moreover, its extent is probably one hundred times that of the Cuban tobacco region, when we take into consideration the fact that acre for acre the percentage of cultivated land at the present moment capable of producing tobacco of the very highest grade is greater in Mexico than it ever was in Cuba in its best days. We can from this easily see what will be the amount produced in the future. Mexico's resources in this direction are practically so great as to make it certain that it will become rich from its tobacco alone. No doubt the result will be finally to cheapen the Habana cigars, and put them within the reach of all."—*H. & C. Mail*, May 7.

would appear that potash and phosphate, separately or combined, do not increase the yield of tubers in these soils.

MANURIAL EXPERIMENT WITH SWEET POTATOES.

As a specimen of the work done in Antigua by Messrs. F. Watts, Government Chemist and Mr. F. R. Shephard of the Schools, we quote the following in full with appended table:—

Seeing that the ash of the Sweet Potato is very rich in Potash and also contains a very fair proportion of Phosphoric acid, experiments were made in order to ascertain whether the application of these two constituents would materially increase the yield. Nitrogen was not used, as in an adjoining field a crop of sweet potatoes had developed such a large amount of leaf and vine,—due as we suspected to an abundance of Nitrogen—that there was some difficulty in securing a crop of tubers.

Four experiments were tried, the plots receiving
 Sulphate of Potash
 Superphosphate
 Sulphate of Potash and Superphosphate
 No Manure.

and each of these was repeated four times: the individual plots measured 100 ft. by 40 ft.

The variety planted was that known as the "Quildane," it was planted early in January 1896 and reaped in June and July. The manures were applied in January. The large potatoes sold at the rate of 3/ per 100 lbs. and the small ones at 9d per 100 lbs. realizing £13-6-0 per acre.

The weights of potatoes and the proportion of large tubers are given in Table XI from which it

AGRICULTURAL-SCIENTIFIC EXPERIMENTS IN ANTIGUA.

(Extracts from Report to the Colonial Secretary.)

GOVERNMENT LABORATORY, ANTIGUA, Dec. 3rd, 1896.

These experiments are a continuation of those which have been carried on systematically since 1892, and consist in the application of known quantities of the commonly employed constituents of commercial manures, to small plots of canes; the experiments being conducted on both "plant" and "ratoon" canes.

The experiments with plant and ratoon canes may be classified as follows:—

(1) Experiments with Nitrogen, in which unmanured plots and plots receiving no nitrogen are compared with plots receiving varying amounts of Nitrogen in the form of (a) Sulphate of Ammonia, (b) Nitrate of Soda, (c) Dried Blood.

(2) Experiments with Phosphatic manures, in which the yields obtained from plots receiving (1) no manure and (2) no phosphates are compared with those from plots receiving varying amounts of phosphates in several different forms

- (a) as Superphosphate
- (b) as finely ground Mineral Phosphate
- (c) as "Double Superphosphate"
- (d) as Basic Phosphate

(3) Experiments with Potash in which the yields from plots receiving (1) no manure and (2) no Potash are compared with those from plots receiving increasing amounts of Potash in the form of Sulphate.

(4) Experiments with various substances, as Sulphate of Lime, Sulphate of Iron, Sulphate of Magnesia, and Marl (carbonate of Lime).

We have now to ascertain whether phosphates, in which the soil is so deficient, and which are so essential to plant life, can be added in any manner which shall prove directly beneficial. It seems probable that Leguminous crops may be benefited by the application, and that if green dressings of Leguminous crops grown with the aid of phosphates be buried in the soil, we may introduce phosphates in a useful form, while at the same time the soil will receive vegetable matter, (humus), which it needs to as great an extent as it needs phosphates. A series of experiments has been inaugurated on these lines.

One of the greatest differences between tropical and temperate agriculture is occasioned by the rapid decay of vegetable matter which goes on all the year round in the tropics; so that much more organic matter is required in the tropics than in temperate regions, in order to keep land under cultivation in good condition. Soils such as these must receive large amounts of vegetable matter to keep them fertile; this may be accomplished by heavy dressings of pen manure, of which the planter rarely has sufficient at his command, or by "green dressings," or by the application of "bush"—(small brushwood, twigs, leaves, grass, seaweed and such like—grown elsewhere and carried on to the fields there to be buried. This latter process however can only be carried out in situations where the requisite material is available; it is a common practice in Barbados and St. Kitts, where its value is recognised. Applications of this kind should be made some time before planting in order that the young crop may not be injured by the fermentation of a large mass of fresh vegetable matter, covered by a few inches of soil; and if even with this precaution there appears to be any danger, the soil in which the "bush" is buried should be stirred with the fork. This method of manuring may be made to convey to the soil all the mineral matter, including phosphates required by a cane crop.* * *

It will thus be seen that such a method of manuring if conducted with the proper precautions will supply in a useful form more plant food than is given by the usual applications of artificial manure, and in such a form as to greatly improve the condition of the soil. This is a method of manuring which we would urge planters to adopt more extensively where ever possible. Green dressing differs from "bushing" only in the fact that in bushing the plant food is brought from a distance and added to the field to which it is applied, thus increasing the store: though something of a similar nature takes place with green dressings which have a deep root range, for they bring plant food from depths greater than the cane roots ordinarily reach and in this way they may be regarded as bringing fresh food supplies to the field. In the case of Leguminous green dressings, the gain of Nitrogen due to the action of the micro-organisms of the root nodules must be taken into account, and renders the use of Leguminous plants preferable to others for this purpose.

FACTS ABOUT COFFEE RAISING IN HAWAII.

The coffee raising industry in Hawaii is yet in its infancy, but it pays from one to two hundred per cent. on capital invested, the coffee being of a superior quality and ranking among the best in the world.

A new coffee plantation will pay original cost and leave a good margin of profit by the end of the fifth or sixth year after planting.

Coffee is worth at present, at the plantation, from 15 to 16 cents per pound, while the annual cost of production averages only 7 cents per pound.

Good coffee land, with unexceptionable title, can be bought all the way from \$5 to \$100 an acre, according to location and condition, and one acre will grow 600 to 800 trees.

A coffee tree in full bearing will average from 2 to 3 pounds of coffee annually, according to age—the life of the tree being from 30 to 40 years.

Much of the labor incidental to the raising and preparation of coffee can be and is performed by women and children, which largely increase the available labor supply and reduces the cost of same.

The cost of clearing the land and preparing the ground for the plants is from \$5 to \$10 an acre.

The season for setting out plants begins in January and ends in September.

Coffee plants can be bought at the nurseries at from \$4 to \$6 a thousand. Plants raised from the seed require eight months' growth before they are ready for transplanting in the field.

If the soil is rich and deep, 600 trees to the acre is a sufficient number; results as regards production of the coffee berry have been found to be more satisfactory with this number than with a greater or less quantity of trees per acre.

Among all marketable fruits, the growing of which is made accessory to coffee culture, the pine apple is the most profitable, especially where the grower has cheap transportation to ports.

The soil and climate suitable for coffee are suitable also for tobacco, corn, beans and oranges, and in the lower lying districts for sugar cane, rice and most of the tropical fruits as well.

The altitude suitable for coffee is from one to three thousand feet above the sea.

The coffee districts are among the healthiest in the country, and the climate suitable for coffee is suitable also for persons accustomed to a temperate zone.

The wages in the principal coffee raising districts, according to official figures, average 50 cents to \$1 a day.

The picking season for coffee commences about July and continues to the end of the year.

Every coffee planter should carry on, simultaneously with his main business, the raising of corn, taro and other vegetables. A few hogs and poultry should also be kept.—*Hawaiian Planter's Monthly.*

INDIA AND CEYLON TEA PLANTING INVESTMENTS.

Few people are aware that the tea industry of India and Ceylon is one of the most important trades of the Empire, and probably the great majority will scarcely credit the fact that a sum exceeding £25,000,000 is invested in the growing of tea in these two British possessions alone. If to this be added the enormous sums employed in transport, distributed yearly in wages to Indian labourers, and contributed to the customs' revenue of the United Kingdom, to say nothing of the vast capital and organisation for the distribution of tea to consumers in connection with the trade, it is obvious that this commodity is one of the standard commercial factors of the Empire. We may further draw attention to its extraordinarily sound and progressive position. Eleven years ago, the proportion of tea imported from China into the United Kingdom was 59 per cent. of the whole, and the Indian and Ceylon teas supplied the balance of 41 per cent. In 1894 the imports of China tea were but 12 per cent, and of Indian and Ceylon tea 88 per cent, and the greater part of the tea trade of the world is yet to be conquered. The tea consumption of the world, excluding the East, is 450,000,000 lb. per annum, and of this 250,000,000 lb. were in 1896 supplied by British growers. The tea-growing industry is supported mainly by capital provided locally in India and Ceylon, which is a striking testimony to what is deemed in these countries its value as an investment, especially when it is considered that the return on capital invested is required

to be much higher in these parts of the East than it is in Great Britain. Usually when capital is sought in England in connection with tea plantations in the East, it is merely with the object of winding up some estate, and is almost invariably supplied by the big East Indian merchants, and those most directly connected with the industry, so that the ordinary public has small opportunity of sharing in its prosperity. It is only within the last few months that the financial newspapers have considered the tea companies worthy of quotation, and the returns of capital, even now, are much greater than in any other form of stable investment. This condition of affairs is likely to continue only until means are offered to the public of participating in this form of investment by the creation of more ready markets for the shares. That such steps will be taken, and shortly, is almost certain, and those who are interested at the outset are likely to reap a golden harvest.—*Limited Liability Review*, May 1.

THE INDIAN TEA CROP ESTIMATE.

A special telegram from Calcutta to our contemporary states:—"The first estimate of the crop is 156,669,000 lb., or about 8,500,000 lb. over the actual outturn of crop in 1896. Estimating the shipments to America, to the Colonies, and to outside ports, and local consumption, at 18,000,000 lb., there remains about 138,500,000 lb., for export to Great Britain." The *Pioneer* states:—"April witnessed the high-water mark in tea exports from Calcutta. The total exports for the past month amounted to 492,241 lb., the corresponding figures for the two past years being respectively 164,662 lb., and 281,253 lb. There was a sudden leap in the exports to Great Britain from 67,104 lb., in April, 1896, to 355,543 lb., in April, 1897, while the figure in 1895 was 246,313 lb. This April showed a slight falling off in the exports to Australia."

INDIAN PATENTS.

Applications in respect of the undermentioned inventions have been filed, under the provisions of the Inventions and Designs Act of 1888, during the week ending 8th May 1897:—

Improvements in Rotary Sifting Machines for Tea or other Suitable Substances.—No 178 of 1897.—Charles William Aunsell, civil and mechanical engineer, proprietor, Aunsell & Sons, Darjeeling engineering works, Toong, Bengal, for improvements in rotary sifting machines for tea or other suitable substances.

Improvements in or Connected with Means or Apparatus for Withering and Drying Tea or other Produce.—No 186 of 1897.—James Shannon Stevenson, tea planter, of Rothes, Hatton, Ceylon, for improvements in or connected with means or apparatus for withering and drying tea or other produce.

Specifications of the undermentioned inventions have been filed under the provisions of the Inventions and Designs Act of 1888.

Fertilized and Fertilizing Materials for Promoting the Growth of Plants.—No. 459 of 1896.—Charles Halford Thompson, F.R.H.S., colonel in Her Majesty's Regiment of Royal Artillery, Eastcliff, Teignmouth, in the county of Devon, for fertilized and fertilizing materials for promoting the growth of plants. (Specification filed 3rd May 1897).—*Indian and Eastern Engineer*, May 22.

THE INDIAN AND CEYLON TEA TRUST COMPANY, LIMITED.

FROM THE PROSPECTUS.

The formation of the present Company has been suggested by the fact that, notwithstanding the established merit of the Indian Ceylon Tea Planting Industry, the Shares in undertakings connected

therewith are, with few exceptions, not readily marketable.

The market for Tea Shares is restricted, owing to the Companies being generally of insufficient magnitude, and to their regulations and constitution (many being formed under Indian and Ceylon law) precluding them from recognition on the London Stock Exchange. Although they earn large profits and offer an excellent security, their Shares are often not immediately realisable, and transactions have to be the subject of special negotiation. This is the frequent experience of executors.

Under these circumstances the intervention of an investment Company, constituted in accordance with the Rules of the London Stock Exchange, and of sufficient magnitude to command the attention on the London Share Market, appears to be needed.

The Capital of the Company will be spread over a number of undertakings, and its Shares therefore offer to investors an opportunity of participating in the prosperity of the Tea Industry with a minimum of risk, and without the difficulty of realisation which has hitherto been experienced. The present prices of quoted Tea Companies show a return on Capital largely in excess of that which might be expected, considering the long established and second character of the Industry. Still larger returns are shown by the Rupee Capital Companies, in whose Shares there are no dealings in London and the amalgamation of which is contemplated by this Company, with a view to offering them for investment in this country.

To meet possible contingencies the Memorandum of Association provides for a wide sphere of operations, but it is not intended to travel beyond the limits of investing in Shares and Debentures and of subscribing and guaranteeing the issue of Capital of existing or new companies connected with the Tea industry, and of purchasing, consolidating and issuing as Limited Liability Companies, Tea Plantations, and small Rupee Capital Companies.

The Tea industry, well organised and controlled, is highly prosperous. The time and capital necessary to establish a tea plantation, tend to limit the business to highly responsible hands.

The market for the produce are also rapidly extending. The proportion of China Tea consumed in Great Britain in 1886 was 59 per cent, and of Ceylon and Indian, 41 per cent; in 1896 the proportions were China Tea 9 per cent and Indian 91 per cent respectively.

The tea consumption of the world, excluding the East, is 450,000,000 lb., and of this 250,000,000 lb. were in 1896 supplied by British growers.

The field for investment is large; the Capital embarked in Tea Companies is estimated to be at least £25,000,000, and the Directors having intimate associations with the East, and the Tea industry in particular, are in the best position to obtain information as to the value of any securities which may come before them.

AN AMERICAN TEA DUTY.—We should not regard an import duty of 5d per lb. (if actually passed) as prohibitory for the United States, provided—as we trust and believe—corresponding imposts are to be laid on coffee and cacao. An advantage to Ceylon and India is that the higher the tea duty, the more it should tell against the cheaper commoner teas of which China and Japan supplies the larger portion. The duty will make up so large a proportion of the retail price in future, that it should be thought a small matter comparatively to give 2d to 3d extra per lb. to get a really good tea. The next question is what will Canada do? Hitherto the Dominion has charged 10 per cent *ad valorem* on teas brought through the States, while direct shipments were admitted duty-free.

Correspondence.

To the Editor.

THE CULTIVATION OF "VANILLA."

Seychelles, Feb. 18, 1897.

SIR,—Knowing no one in Ceylon, I am taking the liberty of addressing you to ask, can you put me in the way of obtaining information as to the cultivation of vanilla in your island? I have occasionally seen Ceylon vanilla, mentioned in Brokers' reports—so suppose a little is grown. What I most desire to know is, could one obtain cuttings of the vine to start new plantations? Has the fungus yet attacked your plants in Ceylon?—I am, sir, yours faithfully,

F. H.

[We referred the above queries to one of the most competent practical authorities in the island—Mr. W. H. Wright—and have got the following reply:—

"I have grown vanilla since 1841 (when I was at Peradeniya) and am still cultivating it in a small way at Mirigama. In 1841 I sent some to England through Messrs. Baring Brothers. I got R55 per lb.—the price of it just now is R7.50 per lb. I can supply cuttings for a new plantation, say, to cultivate 10 acres at R15 per 1,000 cuttings. I am glad to say that I have never seen fungus attacking vanilla plants. I find that vanilla may be cultivated partially under shade, allowing it to grow on Dadap or Eremodo trees planted 30 feet apart and intervening on stumps. The best manure for vanilla is refuse coir-dust which can be had any quantity for nothing, any one who wishes to go in for vanilla cultivation, I will be glad to show them the mode of cultivating it on this estate."

—ED. T.A.]

TEA PLUCKING AND PRUNING & C:
A LETTER OUT OF DUE SEASON.

KELANI VALLEY.

(1) Would you say how far you think Coarser Plucking of Leaf may have had to do with it?

Coarser plucking is the main cause, and this not voluntary but from larger area to pluck and limited labor.

(2) Or the more prevalent attention to Manuring Tea?

Manuring brings the larger yield but does not bring the coolies to pluck it.

(3) Or severe Pruning—cutting the bushes too far down?

Severe Pruning gives a weaker liquor and thus for a time reduces the value.

(4) Or less attention to careful Preparation in the Factory?

No, as much attention as ever is paid to manufacture. Given ample labor and ample Factory room and careful plucking, as good teas can be made now as those of the best years.

(5) How far Shortness of Labour Supply has affected your work in field or factory?

Affected both.

(6) Any other cause that strikes you—apart from (7) Overproduction and Increased Supply in Competition at the Sales?

The Home value of equal Teas of 1893 and 1897 is a very great factor, teas of equal make and look are now sold for 50 per cent less.

OLD PLANTER.

"ACACIA DECURRENS."

DEAR SIR,—In a controversy some years ago, I collapsed when after having received seed from Australia repeatedly of A. Decurrens and all the plants derived therefrom proving decurrent (although the color of the bark differed greatly among plants from the same lot of seed, the bark was mostly a pretty purple; but there were plants with bark of all shades of green). Yet there were local writers who argued that A. Decurrens was not decurrent; named I suppose on the same principle that the earwig is said to be named, i.e., one was never yet known to enter a person's ear.

Possibly you will be surprised at the number of varieties of a de-currens (over 70) yet please note that without exception all are decurrent. If some public-spirited merchant would take the trouble and go to the expense of sending a shipment of the bark to England, it might lead to a new and profitable industry in Ceylon. The result of my own experiment although the analysis turned out so good, and the London valuation so high, and the yield of bark so encouraging: was that the proceeds of the bark in London only covered the expenses after it was delivered into the merchants share in Colombo.

It cannot be so in Australia for the bark is selling at £5 per ton at the shipping post. My parcel being a small one I based the above calculation upon the cost of drying, packing, and shipping charges on Cinchona bark in Colombo. If it can be done for much less, then it is a pity that no merchant came forward to say so. If a decurrens bark is worth £5 per ton at the shipping port in Australia, one would think it would be worth as much in Colombo. The question might be revived. Around Nuwara Eliya, in particular, what a grand thing for the estates to be able to supply themselves with fuel from about the quickest-growing tree we have; and at the same time to harvest a valuable commercial product from the same trees.—Yours truly,

T.

THE CULTIVATION OF RHEA FIBRE.

Kandy, May 24th.

SIR,—I enclose for publication copy of correspondence received from the Rhea Fibre Treatment Company, Limited, London, on the subject of cultivation, decortication and baling of rhea, and the subsequent treatment of the ribbons by the Gomes's process, and offering £10 a ton delivered in London or Liverpool.—I am, sir, your faithfully,

A. PHILIP, Secretary.

(Copy.)

Piccadilly Mansions, 17 Shaftesbury Avenue,
W. London, April 2nd.
Messrs. The Planters' Association of Ceylon,
Kandy, Ceylon.

DEAR SIR,—We have had forwarded to us a copy of your 43rd Annual Report, for the year ending 17th February 1897, and we read with great interest the paragraph therein relating to Rhea Fibre.

We have pleasure in sending you copy of a pamphlet dealing with the cultivation, decortication and baling of rhea, and the subsequent treatment of the ribbons by the Gomes's process, compiled under the direction of this Company, which we venture to think you will appreciate.

You will note therefrom that for the purposes of the Gomes's process treatment, it is only necessary to strip the bark from the stems and to thoroughly dry it, and that no other manipulation or cleaning is necessary.

We are prepared to make contracts for regular supplies and we suggest that you should send to us at your earliest possible convenience, a 2 or 3 cwt. sample for testing purposes, and to form the standard of quality for future consignments.

The price which we were offering is £10 a ton, delivered in London or Liverpool, but in order to encourage cultivators, we should not mind paying a slightly increased price for the first and second year of shipments.

We can assure a market for large supplies, and we believe that we can co-operate to mutual advantage.

We shall be glad if you will reply to this by return, and you can either address us direct, or through Messrs. A. Whitley & Co. of Colombo. If you have any material ready for shipment, and can dispatch it to us at once. Kindly wire us using the "A.E.C. Code" 4th edition.—Yours faithfully,

(Signed) W. T. BELL, Secretary.

THE BULKING OF TEAS AND THE RUSSIAN DUTY ON TEA CHESTS.

Kandy, May 24.

SIR,—I enclose for publication copy of correspondence by the Ceylon Association in London with (1) the Tea Brokers' Association of London as to the necessity of all teas being properly "bulked" before being offered at public sale (2) the Board of Trade as to the duties charged on acme steel tea chests entering Russia.—I am, Sir, yours faithfully,

A. PHILIP, Secy.

(Copy.)

61 & 62 Gracechurch Street, E.C. London, 9th April 1897.

A. Philip, Esq., Secretary, Ceylon Planters' Association, Kandy, Ceylon.

DEAR SIR,—I have the pleasure to enclose for the information of your Committee copies of recent correspondence, (1) with the Board of Trade as to the duties charged on acme steel tea chests entering Russia, (2) with the Tea Brokers' Association of London as to the necessity of all teas being properly "bulked" before being offered at public sale.—I am, dear sir, yours faithfully,

(Signed) WM. MARTIN LEAKE, Secy.

(Copy.)

61 & 62 Gracechurch Street, E.C., 25th January 1897.

The Secretary of the Board of Trade, London.

SIR,—A firm exporting Ceylon tea from London to Russia writes as follows:—

We have recently made a shipment of Ceylon Tea to Russia of which 38 chests were acmes: on these the Russian Customs have charged duty as tin plates amounting to £6. 7s. 4d.

The acme chests are made of thin metal and have of late come into frequent use: the effect of charging duty on the metal chest as well as on the tea will be to exclude from the Russian markets the teas of those gardens that use metal chests.

Can you inform me in what way a representation on the matter can best be made, so as to bring about a change of practice?—I am sir, your obedient servant,

(Signed) WM. MARTIN LEAKE, Secy.

Board of Trade (Commercial Department), 7 Whitehall Gardens, S.W., 2nd February 1897.

SIR,—I am directed by the Board of Trade to acknowledge the receipt of your letter of the 25th ultimo, on the subject of the Customs treatment in Russia of metal chests containing tea when imported into that country.

The Board are in communication with the Foreign Office respecting this matter, and hope to be in a position to furnish you with a further reply shortly.

I am, sir, your obedient servant,

(Signed) W. GIFFEN.

Wm. Martin Leake Esq., Secretary of the Ceylon Association, 61 and 62 Gracechurch Street, E.C.

Board of Trade (Commercial Department), 7 Whitehall Gardens, S.W., April 5th, 1897.

SIR,—With further reference to your letter of the 25th January last and to the reply thereto addressed to you from this department on the 2nd February, I am now directed by the Board of Trade to forward to you for the information of your Association, the accompanying copy of a Memorandum from Her Majesty's Consul-General at St. Petersburg (which has been supplied to this Board through the Foreign Office) on the subject of the Customs treatment in Russia of metal chests containing tea imported into that country.—I am sir, your obedient servant.—(Signed) W. GIFFEN.

W. Martin Leake Esq., Secretary of the Ceylon Association, 61 and 62 Gracechurch Street, E.C.

Memorandum.

Tea when imported in large cases lined with tin and which are cut open for inspection at a Russian Custom house is dutiable at its net weight, and similarly as tea imported in lead casing the tin casing is not liable to duty.

Tea imported in small cases or canisters is likewise dutiable at its net weight, but the small cases or canisters are subjected to a separate duty as tin plate or R2-25 copecks gold per pound or when laquered R3, or painted and gilded R6 gold per pound. There are no specific orders for this practice which appears to be based only on the analogy applicable to the case and afforded by the orders of the Customs department of the 17th October 1883, and the 12th June 1890, which direct that tin cases containing weaver's reeds, leather belts, sewing needles, aniline dyes and other manufactured goods shall, on importation pay a duty of R2-25 copecks gold per pound under section 151 of the Customs Tariff.

(Signed) JOHN MITCHELL.

St. Petersburg, March 19th, 1897.

Circular letter referred to.

61 & 62 Gracechurch Street, London, 9th April 1897, E.C.

DEAR SIR,—A complaint has reached the Tea and Produce Committee from the London Wholesale Tea Dealers' Association that,

"The requirements of Clause 4 in the conditions of public sales which states that each parcel has been inspected before sale, and has been hulked (if necessary) have not been carried out in a great many cases."

The Committee regrets to find on enquiry that this complaint is not altogether unfounded.

Inasmuch as careless or neglected bulking of necessity involves unreliable samples, the complaint is undoubtedly a serious one.

I am directed therefore to invite the attention of importers of Ceylon tea to the imperative necessity for complying with the conditions of the clause referred to, so that buyers may operate with the fullest confidence in the future.—Yours faithfully,

(Signed) WM. MARTIN LEAKE, Secretary.

(Copy.)

The Tea Brokers' Association of London,

Mincing Lane, E.C., 26th March 1897.

W. MARTIN LEAKE, Esq., Secretary, The Ceylon

Association in London.

TEA BULKING.

DEAR SIR,—I am instructed by my Committee to send you the enclosed copy of letter received from the London Wholesale Tea Dealers' Association.—I am Dear Sir, yours faithfully, (Signed) W. G. PRICE, Secretary.

London Wholesale Tea Dealers' Association,

17th March 1897.

To W. G. PRICE, Esq.

TEA BULKING.

DEAR SIR,—At a meeting of my Committee held on Monday, the following resolution was unanimously passed, namely:—

The Committee find that the requirements of Clause 4 P.S.C. which states that each parcel has been inspected before sale, and has

been bulked (if necessary) have not been carried out in a great many cases and they must insist on this condition being faithfully observed.

In the event of any parcel not having been bulked in the London Warehouse, a statement to the effect that it has been bulked in India or Ceylon and inspected in London should be inserted in the catalogue.

I beg to request you will be good enough to bring this subject before your Committee, with the view of preventing any further inconvenience which now too frequently results from the irregularities mentioned.

I am &c., (Signed) W. SEDGWICK, Hony. Secy.
The Secretary, Tea Brokers' Association of London.

61 & 62 Gracechurch Street, London, April 9th.

W. G. PRICE Esq, Secretary, Tea Brokers' Association of London.

DEAR SIR,—I have laid your letter of 26th March with its enclosure from the London Wholesale Tea Dealers' Association before the Tea and Produce Committee of this Association, and in reply I am to forward for your information and that of the wholesale Tea Dealers copy of a circular letter addressed to members of this Association and to other importers of Ceylon tea. My Committee hopes that there will be no further cause of complaint.

I am, dear Sir, yours faithfully,
(Signed) W. MARTIN LEAKE, Secy.

TEA IN RUSSIA.

Kandy, 2nd June.

SIR,—I enclose for publication a copy of the translation from a Russian newspaper received from Mr. Rogivue about Tea Cultivation in the Caucasus.—I am, sir, yours faithfully,
A. PHILIP, Hon. Secy., C. P. A.

Translation from the *St. Petersburg Herald*, 16/23 February 1897. Forwarded by Mr. Rogivue.

TEA CULTIVATION IN THE CAUCASUS.

There are about 140,000 tea-bushes in the plantation of the Crown Domains, of which 45,000 are from seed obtained from China through the commission which was sent there.

The planting was most carefully done, and the growth of the bushes has been excellent. Experienced tea-growers from China and Japan, as well as an Englishman, who has been engaged in tea planting in India, were entrusted with the planting and treatment of the bushes. Next season's planting is to be done with 200 lb. (Russian) or about 30 maunds seed from China. On K. S. Popow's estates in Tschakra, Kaprischosts and Ssudidawri about 20 Desjutins (about 70 acres) have been opened in tea, and the number of bushes is estimated at about 70,000 of 1 to 3 years' growth and upwards.

On A. A. Ssolowzow's estates about 10,000 plants have been put out. Here the cultivation of tea was first introduced and some of the bushes which are from 7 to 9 years old have already given good crops.

It is however to be regretted that the inhabitants of these districts do not take to the cultivation of tea, although it grows very well in Givira, Mine-reha and S. W. Imeritia and many of the Agricultural Schools in the town have well established bushes in their gardens.

MYROBALAMS AND ARALU NUTS.

Hapatule, June 3.

DEAR SIR,—Being a reader of your *Tropical Agriculturist*, I notice in the market rates quoted of Ceylon produce, that Myrobalams are 8s to 7s. Is this per cwt. or per bushel? [Per cwt.—ED. T.A.]
I should be very much obliged if you could give

me any information regarding the licence you have to pay for gathering Aralu-nuts, and what merchants in Colombo and London purchase this product?—Yours faithfully,
H.C.A.

[Aralu-nuts are gathered chiefly in the Uva Province, and the Forest Department sells the rent or right of gathering yearly—in 1893 it fetched R4,000; 1895, R1,000 offered.—E.C.] O.D.

FLIGHT OF BUTTERFLIES NORTH OF KANDY.

Ooonoagalla, Madulkele, 9th June.

DEAR SIR,—An immense flight of butterflies is passing due south today. The flies we usually see at end of April. I enclose several specimens. Sky clear with light breeze from south-west. We had a little south-west wind with showers a few days ago; but the weather today is more like the beginning of April than the 9th June.—Yours truly,
M. H. THOMAS.

[The butterflies are of a type common in such flights even on the sea-coast; but November-December is the usual season for "the migration of butterflies"—in the teeth of the north-east monsoon—and we cannot recall such an experience as the present one in June? It will be seen that the flight is reported from Kotmalie and Dimbula as well—ED. T.A.]

ALBIZZIAS IN B. C. AFRICA.

Dunraven, Estate, Mlanje, 14th March 1897.

Dear Sir,—As several planters have been sending samples of our local trees, which answer somewhat to the description of Chikwani to me for identification (but all have turned out to be different), I write to inform them how they can unmistakably identify *Albizzia Fastigiata* Oliv. unless it turns out that they have found some other *Albizzia* in the country, which I have searched for and failed to find.

When the roots of Chikwani are examined you will find little lump-nodules about the size of small white beads which when squeezed exude a white milky substance, sitting quite unmistakable and prominent along the fibrous roots; not a rough lumpy surface on the bark as one gentleman was sure were the nodules referred to. They are the same as those attached to the *Albizzia Moluccana* plants (although I have no plants myself) I am quite certain the nitrogen fixers will be found by those who have purchased seed from the A. L. C. and grown the plants.—I am, etc.,
HENRY BROWN.

P. S.—Chikwani does not seem to be in Blantyre or Zomba for I have had samples of the nearest trees to it but not the identical trees—neither are they *Albizzia*.—*Central African Gazette*.

[What does Mr. Brown, formerly of Matala, mean by coupling *A. Moluccana* with "nitrogen fixers."—ED. T.A.]

DEAFNESS.

An essay describing a really genuine Cure for Deafness. Ringing in Ears, &c., no matter how severe or long-standing, will be sent post free.—Artificial Ear-drums and similar appliances entirely superseded. Address THOMAS KEMPE, VICTORIA CHAMBERS, 19, SOUTHAMPTON BUILDINGS, HOLBORN, LONDON.

COFFEE PLANTING IN THE PROVINCE OF COORG.

We have before us the Administration Report of the Province of Coorg.

The special interest which Coorg possesses for us is connected with its cultivation of our old staple. It was once a rival of ours in the production of coffee, and now that we have passed literally to the sore and yellow leaf, Coorg for some time supplied us with what was believed to be fungus-proof seed. It is the fault neither of Coorg nor its coffee, that the life history of *Hemeleia vastatrix* does not encourage the hope that any variety of the coffee tree or coffee bush can resist the fatal attentions of the insidious pest. Whether in Coorg itself the coffee bush is free from the fungus, the Report does not state. We doubt if it is; but there is no diminution there in the acreage under cultivation. The total area of land under coffee had increased, for the period under report, from 84,592 acres the previous year to 84,991 acres. The increase of 399 acres is not much; but what is remarkable is that this product covers the largest acreage of all, so far as appears. Even the wet lands under rice cultivation fall short of the acreage of coffee land by 8,000 or 9,000 acres; while dry lands under dry and garden crops cover only little over 1,500 acres. Nor is it stated that the figures relate chiefly to abandoned land, as we find the whole extent assessed—424 European estates covering 30,979 acres and 7,094 native estates 54,012; but the yield, if the official figures are correct, must be very disappointing. The coffee crop for the year, though 800 tons larger than for the previous year, amounted to only 3 650 tons which, according to the familiar local terms, are equal to 14,6 0 cwt.; and that works out one-sixth of a cwt. an acre. It cannot possibly pay to cultivate coffee for such returns; and we suspect that the assessment continues to be levied on the full acreage of estates, the better part of which has gone out of cultivation. If so, we cannot but condemn the heartlessness and shortsightedness of a policy which does not take account of the ability of the land to bear the burden placed on it. Even taking the European estates alone, which represent the smaller acreage, the total outturn would give less than half a cwt. to the acre! We are not surprised, in view of these facts, to learn that a movement is on foot to place the abandoned coffee estates on the Sampaji Ghat under tea; but, while sympathising with those who feel compelled to betake themselves to a new product, we are bound to note that the circumstances under which this island resorted to tea were different. Then tea sold from 2s to 3s a lb.; British grown teas formed an inconsiderable fraction of the world's production; and the supply was not in excess of the demand. Now, tea sells at a lower price than it ever did—1s would be a high average; the current prices leave only a small margin of profit to the majority of estates, though well-situated fertile plantations still yield gratifying returns; and the supply being in excess of the demand, there is the constant apprehension of still lower prices. It is often better to bear the evils we know than to fly to others we wot not of. Some of the Coorg lands—the extent is not specified—appear to be under cardamoms; and that is a product for which the prices and the demand are encouraging; but it chiefly affects ravines and moist situations; and spices can very easily be overdone, as many found to their cost here with cinnamon.

PLANTING NOTES.

BEE'S VENOM AS A REMEDY.—A novel undertaking in the manufacture of drugs has been begun by two young Pennsylvanians, who have commenced the extraction of the poison from honey-bees. They have two different ways of collecting their crop of venom. In the first, the bees are caught and held with the abdomen in a small glass tube until the poison sacs have been emptied. In the second, they are placed in a bottle on wire netting, and enraged until the tiny drops of venom fall into the alcohol which fills part of the bottle. This venom is said to be a remedy for cancer, rheumatism, snake-bite, and a hundred other ills of humanity.—*Chemist and Druggist*, April 24.

THE IMPORTATION OF INDIAN TEA AT THE PORT OF BATOUM.—The Indian Tea Association (London has addressed the following letter), through the secretary, Mr. Ernest Tye, to the Secretary of State for Foreign Affairs: "I am desired by the committee of this association to address your lordship with reference to the prohibition issued by the Russian authorities against the importation of Indian tea at the port of Batoum, which was referred to in a telegram from the Secretary of State to his Excellency the Viceroy of India under date March 10, as follows:—'Batoum: Importation of Indian Tea Prohibited.'—The port of Calcutta, from which Indian tea is shipped is, and has been hitherto, entirely free from any attack of plague, and is very distant from any place where the plague prevails, and my committee would respectfully invite your lordship's attention to the fact that the prohibition is regarded in India as the result, not so much of sanitary precaution, as of commercial jealousy of India and its industries. My committee fears that unless prompt measures are taken to have the prohibition removed other nations will follow the evil example set by Russia, and that grave injury will result to the Indian tea industry. I am therefore directed by my committee to beg that your lordship will be good enough to take such steps as may seem to you expedient, with a view to bring about the removal of the restriction against the importation of Indian tea at Batoum or elsewhere."—*H. & C. Mail*, April 23.

HEMP CULTIVATION IN BOLOGNA.—One of the most important agricultural products of the provinces of Bologna and Ferrara is hemp (*Cannabis Sativa*). Bologna hemp is generally manufactured into yarns and canvas. The Ferrara quality is principally used for rope making. The former is a finer fibre than the latter, but not so strong; they are both however held in high esteem in textile centres abroad, according to the United States Consular Agent at Bologna, chiefly in Germany, France and Spain. The cultivation of hemp has greatly developed in Bologna and Ferrara, owing to the favourable conditions of the climate and soil, which are not easily found in other countries. Hemp may be cultivated between the equator and 60° latitude. Chemically the land must be siliceous, argillaceous, calcareous and rich in azote. Physically it must be soft, fresh and deep. In addition the land must be abundantly manured. Sowing generally takes place in the spring, owing to the necessity of a temperature of 46° Fahrenheit, and a moderate degree humidity. It is preferable to sow by machine, this system saving seed, and the sowing being much more regular. The land must be previously deeply ploughed. After sowing the land requires to be hoed, and much other work is necessary, such as the extirpation of weeds, &c., in order to obtain an abundant crop. The crop ripens in August or September according to the weather. It consists of stalks about three metres long. These stalks are placed in bundles and put into ponds expressly constructed, where they remain about a week. They are then dried and scutched by means of a complicated process, which produces the fibre ready for market.—*Journal of the Society of Arts*, April 9.

COFFEE PLANTING IN NYASSALAND.

Mr. G. M. Crabbe formerly of Great Western and afterwards El Teb, which place he left to superintend the Nyassaland Coffee Co.'s property in Milanji, Central Africa, and quitted the place on medical advice, being attacked many times with fever, and who arrived here the other day, has left for upcountry. According to particulars afforded by Mr. Crabbe to our contemporary, he had not been in Milanji more than three months, when two of the Buchanan Brothers, whose place was at Blantyre, died, and the third brother is now dead also. They were the leading men in the country, possessing a thousand acres or thereabouts. John Buchanan had been out in Central Africa about 18 years, connected with the Blantyre Mission Station. He started the planting down there, but soon after Mr. Crabbe's arrival, John Buchanan and his brother Robert died within two months of each other. Planters in that part we are constantly falling ill with fever, and many die. The population of white men in Milanji was only seventeen, including the Administrator and his assistant. When the place is fully opened and developed, Mr. Crabbe thinks it may become healthier, but at present it was a most dangerous country. The country is undulating, like the Assam district, and it has a rainfall of about eighty. The temperature is cool and equable, but the place is particularly unhealthy from the middle of November to the end of February, which is the planting season. The pioneer of Milanji is Mr. Henry Brown, who was formerly an Inspector in the Ceylon Police. When he left here, in 1890 or 1891, he went to Central Africa in connection with the work proceeding at the Lakes; but in a short time he took to coffee planting. When he left the Company's property they had 210 acres opened, and last year they opened another ten acres, making 250 acres opened, but another 250 is to be opened this year. The jungle which has to be cleared is very heavy, but the soil is by a long way the best soil that can be found there, and is very dark-red in colour. Mr. Crabbe's place has been taken by Mr. Moggridge, who was formerly with Mr. Cotton, on Dammeria, Passara. He has with him as assistant Mr. Robin, who also hails from Ceylon, having been a planter with Mr. Metcalfe in Pundaluoya. They came out to Mr. Crabbe a year ago last May. Robin has suffered very badly with fever. Five miles off Mr. Crabbe's place was an estate belonging to Mr. Moir, who was formerly Manager of the African Lakes Company. He had about 180 acres opened in coffee and on the other side was Mr. Henry Brown who had about 200 acres opened. Mr. Crabbe had some coffee in full bearing, and he had also a few tea bushes, but they were not a good job. Then about ten miles off Mr. Bradshaw had about 180 acres. His was a very good place. His oldest coffee was about five years of age, and he got a crop of 30 tons last year. Then, there was a small estate of 60 acres belonging to a Mr. Simpson, who, in addition to coffee, has gone in for a few native products. That is about all. There were no factories, and all the pulpers are worked by hand with the exception of those at Mr. Moir's place who has the only water-wheel in the country. But the great thing they have to contend against, said Mr. Crabbe, was the want of good seed. The coffee is of the Arabian sort, but this want is greatly felt, and something will have to be done with regard to getting better seed. The Nyassaland Coffee Company did try to introduce Brazilian seed, but it didn't answer—it failed to germinate. All the seed they had was got locally. No coffee seed from India or Ceylon is allowed into the country on account of leaf disease, nor is tea seed allowed, though some sent by Mr. Carson from Ceylon managed to get in and it turned out a failure. It was Indian seed; but it got in as the Commissioner at that time was anxious it should be started. The coffee is planted under shade there. The administration seem to have done very little for the country as far as helping the planter goes. There is a great want of roads and transport facilities. All produce was sent to Chiromo

on the river Zambesi, 70 miles away on niggers' heads, and though there was a river near, and it led to Chiromo, it was not navigable. From Chiromo the produce went to Chinde; Beira, of course, being the port of export. Labour was plentiful, with the exception of the four wet months. That time the natives mostly employ in working their own gardens. A lot of labour comes from Lake Nyassa, the people coming down a distance of over 200 miles. The labourers were paid in calico, three shillings a month, so they were cheap. The local labourers only got two shillings' worth of calico a month. They had no trouble either with advances or tunds.

KOLA.

THE AMERICAN MARKET.

The demand for kola in the United States has increased very materially within the last three years. In fact, previous to 1894 there was practically but little used. At the present time, American firms are among the largest consumers.

African and Jamaican Kola.

The introduction of Jamaica kola in this market dates from my visit to your island, in the winter of 1893-94. Since then Jamaica kola has had a more or less ready sale at a good price. It is a mistake, however, to suppose that Jamaica kola will sell at a price above that of any other kind and it is especially a mistake to think so when Jamaica kola is badly handled as to its gathering and shipment.

At the present time by far the largest amount of kola consumed in the United States comes from Africa, and probably about ten pounds of African are sold to every pound of West Indian. There are several reasons for this. First—African kola is better known having been introduced into the European markets two or three centuries ago. And, secondly, the African kola is much better cared for in its gathering and shipment. As an illustration: I have a stock of African kola nuts fully one year old, and the nuts are in the same condition as they were when first picked. Whereas the first specimens of Jamaica Kola as prepared for the market deteriorate on the five and six days' voyage from Jamaica to New York.

Through your Society and the Botanical Department and by the aid of the public press, I have endeavoured to induce your people to prepare it in a proper manner. While I have practically succeeded, the experiment so far has been an expensive failure.

Hints for Shippers.

The main trouble is that your people wait until the kola is partially dried and rotted upon the tree before they pick it. Whereas they should be picked as soon as the pods are full, before they break open and dry. Next, as soon as taken from the tree, they should be taken from the pod and the thin outer skin, which is loose and pulpy, should be carefully washed off, so that this entire coating is removed. The nuts may then be shipped at once, packed in barrels—that is, if they are sold to the user who will use at once. But if they are to be sent on consignment or if they are to be kept for any length of time before using, they should immediately be washed and covered completely and tightly with wetted leaves. The best way is to line a basket about one inch thick with heavy green leaves which are thoroughly wetted. The lining should be complete, without any cracks or breaks. The nuts should be picked over; if any are bruised, broken or over-ripe or starting to rot, they should not go into the collection. They should be carefully laid in so as not to break or bruise them, or split them open. They may then be sprinkled down with water, and carefully covered with wetted leaves. Nuts thoroughly done in this way will keep for at least a year. In fact, I have had them for 18 months. I have thought that I would ship to Jamaica a basket of nuts as prepared in Africa for shipment, that your people might see exactly how it is done. It is a simple matter and yet one which I have been unable to get your people to accomplish,

The principle involved is, that mouldy nuts, over-ripe or a few rotten nuts, spoil the whole of the shipment and that the outer pulp which is easily decomposed, shall be washed off. Also that the nuts shall be covered so that the mold germs from the air or external objects shall not reach the nuts. Also that they do not dry out. At the same time air must reach them, but through the filter of leaves. I have received nuts from Jamaica packed by every method except this one. In cases where I was able to use the nuts at once, it did not make so much difference, but if you are going to supply them for the general market, you will have to have them more perfect.

The Future of Kola.

As to the consumption of Kola. Kola has been brought to this or any other market in sufficient quantities prepared in the right way, to supply the demand for a preparation of kola to take the place of coffee. What is now consumed is for medicinal preparations, and for this purpose there is plenty to be had at rather low prices, considered as a drug. But when we come to consider it as an article of food as beverage, that means millions of pounds and the transportation from Africa would preclude the possibility of its coming into competition either with tea or coffee.

Dealers and manufacturers have therefore contented themselves so far to supply only medicinal preparations awaiting such time as they can be assured that they will have a supply that can be depended upon, prepared in the right manner, before placing the beverage upon the market. Green nuts are in the greatest demand at the present time and the demand is constantly increasing. In regard to the drying of the nuts, even African dried are very unsatisfactory for beverage purposes. For the purpose of which I speak, none of the nuts dried either in Jamaica or elsewhere are at all satisfactory. In fact this is what has precluded its adoption. There is a proper method of drying them, of which I may send you information later.

It is difficult to tell the amount now consumed in the United States as they are arriving from all sources in such variable quantities. I have a knowledge of one concern that used about 100,000 lb. last year.

There are many concerns who use a considerable amount and the demand is rapidly increasing. Further than this, I am not able to state.

T. B. KILMER.

New Brunswick, N. J., 17th March, 1897.

THE INDIAN AND CEYLON TEA TRUST CO., LIMITED.

This Company, the prospectus of which has now been before our readers, introduces us to a new departure in Limited Companies connected with tea. It seems to us that full justification for the formation of the Company is afforded in the prospectus; for there can be no denial of the number of small yet prosperous Tea Companies in India and Ceylon whose shares are scarcely known beyond a limited circle. But we regret to find a section of the London press by no means favourable to the new Company. Here, for instance, is what the *Daily Chronicle* of 12th May has to say on the subject:—

THE INDIAN AND CEYLON TEA TRUST COMPANY, LIMITED.—Capital of £250,000 in 49,800 ordinary shares of £5 each, and 1,000 deferred shares of £1 each. The present issue is 30,000 ordinary shares and 1,000 deferred shares. We do not like the principle of deferred shares, which in this case are entitled to divide the balance of profits equally with the ordinary, after a dividend of 7 per cent. has been paid on the ordinary shares. This Company is formed on the usual principle of trust companies

of spreading the risks over numerous undertakings, but it has usually been the case that, as now, prices are high when the purchases are made, and there is always the possibility that the securities may be selected to suit the interests of the sellers rather than the buying company. We should not advise our readers to subscribe.

Of course, in this or any other Trust Company, everything depends on judicious management, and therefore on the character, judgment and experience of the men directing its business. In the present instance, we should say, these requirements, both as regards India and Ceylon, are well fulfilled; and we do not see why the "Indian and Ceylon Tea Trust Company, Ltd." should not have a long and prosperous career and prove a great convenience and benefit to the shareholders in the smaller Tea Companies of both countries.

TEA AND COFFEE.

The advocates of the Free Breakfast Table had an opportunity last night of once more bringing their plausible but impracticable doctrine before the House of Commons. Mr. Arthur O'Connor moved to reduce the tea duty to 2d in the pound, fortifying his proposal by the usual arguments, which, however, failed to convince the House. The Chancellor of the Exchequer had a complete answer to the suggestion in the fact that he cannot afford to sacrifice a tax which brings in £1,800,000 a year, but he also pointed out the injustice of giving up such a source of revenue at a time when direct taxation has become an oppressive burden. There can (says the *Globe*) be no doubt that whenever Sir Michael Hicks-Beach or a successor in his office finds himself in the happy position of being able to reduce taxes the income-tax payer has the first claim to relief. Nothing could be more impolitic either, than to diminish the yield of profitable indirect taxes which experience has shown cannot be again augmented in time of need. Sooner or later the removal of two-pence from the tea duty would inevitably mean the addition of a penny to the Income Tax. Nor is there the slightest necessity for the reduction. Tea is cheaper than it ever was, not because the duty was lessened a few years ago, but because of the enormously extended area of tea-cultivation in India and Ceylon. There is reason to believe that the consumer was but very slightly benefited by the change, and another reduction would probably do him no more good. Something might be said for increasing the duty on coffee, the wholesale price of which has declined so enormously that the consumer could hardly be called upon to share it, but unfortunately coffee is ceasing to be a necessary of life to the masses. Its consumption is steadily growing smaller year by year. That is largely due, we dare say, to the fact that few English people know how to brew a cup of coffee properly. But whatever the explanation, the decline is patent, and there is no likelihood that it will be arrested.

MEDICINAL PLANT CULTURE IN NICARAGUA.—U.S. Consul Thomas O'Hara, of San Juan del Norte, Nicaragua, has transmitted to the Department of State the translation of a decree signed by President Zelaya, having for its object the encouragement of the cultivation of the vanilla bean, and of the plants from which the balsams of tolu, copaiba and others are extracted. The decree provides that persons cultivating one thousand or more plants of vanilla or balsam shall be entitled to a premium of 10 cents for each plant, and shall be allowed to acquire plots of government land not exceeding 346 acres on exceptionally favourable terms.—*Chemist and Druggist*, April 17.

Vol. IX.]

JULY, 1897.

[No. 1.

OCCASIONAL NOTES.

We note with satisfaction that Mr. Willis, the new Director of the Royal Botanic Gardens, is bent on bringing together the sciences of Botany and Agriculture as allies in the development of the vegetable resources of the Colony. In a communication made by him to the *Government Gazette* of June 11th, he throws out some suggestions for carrying out this idea. We are glad to find that the end sought and the means proposed are such as we are in entire sympathy with. Indeed, we have already anticipated Mr. Willis in his suggestions as will be seen from past issues of the Magazine, and official annual and special reports to Government in which similar proposals have been made, over and over again. It does not, however, much matter with whom the proposals originated, so long as they are carried out.

An experiment in bee-keeping is about to be undertaken at the School of Agriculture, provided Government favours the project. There is indeed much to be studied in connection with apiculture in Ceylon, past experiments failing to a great extent owing to a too great reliance upon western methods and the adoption of European hives. Mr. Charles Andree, of Kurunegala, who has had considerable experience in bee-keeping has constructed a hive specially designed to suit the habits and requirements of the Ceylon honey bee. Two of these are now on view at the School of Agriculture. It is intended, as soon as sanction is obtained for the experiment, to stock the hives, and so give the students of the school an opportunity of learning

the details of apiculture, an industry which, perhaps, more than any other, is suited to the conditions of our villagers. We shall have more to say about bee-keeping and the new Ceylon hive in our next.

We are glad to learn that Mr. Chinniah, the Government Veterinary scholar at the Bombay College, has received orders to thoroughly acquaint himself with the method of preventive inoculation for rinderpest recommended by Dr. Koch who is now in India. Quite lately it was stated that Dr. Edington of the Cape laid claim to have discovered a method of inoculation which renders the subjects operated on permanently immune, and alleged that Dr. Koch's method only confers temporary immunity. It would not do to give credit to a mere report such as this without hearing the facts of the case; we are therefore awaiting the Cape papers for full details as to Dr. Edington's experiments since Dr. Koch's departure from South Africa.

SEASON REPORTS FOR MAY.

Western Province.—Paddy. Yala sowing over, condition of plants good. Except in the Pasdum Korale, the supply of fruits and vegetables was good. A good yala harvest is anticipated.

Central Province.—Paddy. Maha harvest over in Kandy district, going on in Nuwara Eliya; in Matale, yala fields in plants. Prospects generally fair.

Northern Province.—Paddy. Threshing of Kalapokam paddy going on, and cultivating of Chirupokam progressing. Rainfall in Jaffna 43 in., in Mannar 10 in.

Southern Province.—Paddy and dry grain. Plentiful yala harvest expected in Galle district; fair prospects of paddy crop in Matara and Hambantota. Fruits and vegetables plentiful in Galle, scarce in Hambantota.

Eastern Province.—Paddy. Threshing of Murrari crops in progress in Batticaloa. The murrain in Batticaloa North has created a scarcity of buffaloes for ploughing. Prospects of pinmari crops in Trincomalee satisfactory. Tobacco harvested and dried and fetching higher prices than usual.

North-Western Province.—Crop prospects generally good.

North-Central Province.—Rainfall at Anuradhapura 1.15 in. Outlook for paddy generally satisfactory. A few cases of murrain among cattle, but active steps were taken to stamp them out.

Uva Province.—Paddy. Maha crop ripening, only middling owing to damage by flies. Fruits and vegetables plentiful and cheap.

Sabaragamuwa Province.—Paddy. Maha crop good on the whole, Yala sowing going on. Health of people and cattle satisfactory.

Recorded by A. R. JEREMIAH.

THE BORING BEETLE INFESTING CACAO.

"You have followed the correspondence about the boring beetle infesting cacao," said Fig.

"Well! I have, partially," replied Potts, who was an old man with something of the cynic in him and possessing the air of one who was not likely to be troubled very much with the conduct of beetles or anything else in life.

"Do you think" said the former "the ravages of this insect would ever likely put an end to the cacao industry of the colony by the extermination of the plant, as the *Hemileia vastatrix* destroyed the coffee?"

"You don't want the beetle?" said the latter looking bored "to do that, so long as you have got the planter. Did he not prove himself to be the enemy of the coffee?"

"I envy your assurance" said Fig with a glare. "How do you make out that the planter who fosters his cacao with such care is its enemy?"

"In the same way" replied Potts "that the fostering care of a child is inimical to a kitten, a robin or a grasshopper; or any other pet that a child may fancy. However well-meant its attentions may be, they are unsuited to the conditions of life of the pet, which falls a victim to its attentions."

"How did the Ceylon Planter kill the coffee plant" said Fig. "Did he not attend to its requirements?"

"Requirements"! exclaimed Potts. "Did it require to be cut down to 18 inches from the ground, any more than a fox terrier needs its tail to be docked and its ears trimmed so as to suit the taste of the dog fancier! Did the laws of Nature or the results of evolution blunder in the length of tail given to the dog, or the height and shape given to the coffee plant?"

"But we had to cut the coffee tree down" said Fig "in order to facilitate the harvesting of our crop, and it bore a better berry under this treatment."

"So it did" interrupted Potts "for a time."

"And we pruned it, and handled it" continued Fig "and the bush was all the better for it."

"And you helped Nature" added Potts "as you think, by running counter to its established provisions."

"But we manured the plants liberally" said Fig,

"And stimulated the plant to bear heavy crops" echoed Potts "regardless of the requirements of the tree in other directions, which are as inscrutable to the agriculturist as a thousand other things are in Nature."

"But we had to get in our estimates" said Fig, "and we got them in successfully for many years."

"Yes" said Potts, "the crop was the principal object of your cultivation and the test of your estate. Everything was crop, you fixed your own standard of yield per acre. You fixed upon the height and shape of the bush. You fixed upon the rule that coffee should be grown in the open like the turf on a racecourse, regardless of the conditions under which the tree flourished in its native habitat where you found it. And you do not evince the least prick of conscience that you have done the least violence to that plant."

"Well" said Fig, "what have we done to the cacao plant?"

"You have cultivated it" said Potts. "Is that not enough?"

"Really" said Fig "you are very provoking."

"Where" said Potts "did you obtain your hints from for the cultivation of the cacao plant?"

"From the West Indies of course" said Fig "and other countries where the tree was cultivated before we got it."

"And where did the West Indian planters get their hints from regarding the treatment of fruit-bearing trees?" said Potts.

"From enlightened Europe" said Fig triumphantly. "See how successfully the farmers are with their apples and peaches in England."

"Yes, yes, that is alright in England" said Potts, "where your summer does not extend beyond three months in the year, and where the tree has rest

and in such a climate too that if the farmer did not prune and handle and attend to his trees in the way he does, he would probably get no crop at all. You have yet to satisfy me that this mode of culture is applicable to tropical agriculture; that you should prune or handle, and so admit more sunlight and hot air to the trunk and stems of a cacao tree than Nature has provided."

"We don't prune the cacao now" said Fig.

"You don't prune the branches now" retorted Potts "I grant, but do you mean to say you do not use the knife at all?"

"Yes, we do" replied Fig, "but that is only to take out the suckers."

"And pray what is the sucker?" queried Potts sarcastically. "It is a superfluous growth, I suppose, in your estimation, what Nature might well have dispensed with! So the planter steps in with his cultured ideas and the pruning knife to correct a freak of Nature. Eh?"

Fig appeared somewhat put out by this retort. But it was only for a moment.

"Why! we should lose half the crops if we allowed the great big gormandizers to sap the tree" said he.

"Aye the crop again" said Potts. "Always in a hurry to harvest the crop. The main chance isn't it? Why should we cultivate at all but for the crops you may say; well, you are welcome to your crops, but have you any right then to complain if the tree which bore you these heavy crops under you stimulating attentions declined prematurely and came to an untimely end?"

"But they are not suffering from decay" said Fig, "it is the beetle *Tomicus perforans* that is doing the mischief."

"Then you have not drawn the most obvious conclusion from the correspondence before you" said the old man.

"Take the letter of Mr. Jas. R. Martin dated 13th June. Read the following paragraph:—

"We agree, however, on two points, first, that this disease is not a root disease; and secondly, that it is the work of a Poochie. Your correspondent is also certain that if a diseased tree is cut down, *the sucker which grows from the trunk, grows into a healthy tree.* This is most valuable. So on these three points something has been learnt."

"Now I venture to assert that if the beetle was indiscriminate in his attack, the sucker which grows from the trunk grows not into a healthy tree, but continues to afford food and shelter to the beetle just as much as the other parts of the tree yielded before, and so the ravages would continue till not a vestige of the estate would be left. The study of the beetle, therefore, becomes a question of secondary importance, and the study of the tree the primary issue; for this one fact alone, independently of others, affords incontrovertible proof, coming as it does in the testimony borne by the very planters who are charging the beetle with grave crimes and misdemeanours, that certain altered conditions in the sap, bark or wood of the tree have attracted the beetle to attack it."

"There is a good deal in that" said Fig.

"Now take the letter from Greenwood estate which appeared in the *Observer* of 7th May last," continued Potts.

"The writer would have it that any altered condition of the tree is not the source of attraction, and that the trees attacked are healthy."

"Yes," said Fig "the trees on that estate were healthy and robust and shewed no signs of decay."

"That" replied Potts "can be asserted only with a limitation as far as the human eye can discern. You can no more assert that certain stems and branches of the cacao on that estate had altered in their healthy condition and undergone chemical changes rendering them suitable to the wants of the beetle, because you do not see the changes perceived by the beetle only, any more than you can assert that the beetle should not attack Greenwood estate, because the proprietor chose to give it the name of Greenwood."

"Do you maintain" said Fig "that *Tomicus perforans* confines his attentions to decaying vegetation only?"

"The evidence supplied by the correspondence certainly goes a long way to support the theory" said Potts. "The writer from Greenwood has cited the instance of an attack by *Tomicus* on the beer barrels in the Commissariat Stores of Burma and Lower Bengal, which the writer adds led to the naming of the insect 'Tippling Tommy' by the soldiers."

"Well now Tomny Atkins I think was not far out in associating *Tomicus* with fermented liquors."

"Take the instance given by the proprietor of Greenwood himself. The depraved beetle does not appear to have stopped at vulgar beer, for he is said to have broached the proprietor's wine casks in 1882." He says: "After two weeks I found one hogshead empty and of the other quarter had oozed out through a great many drillings made by 'Tommy.' These facts certainly point to a taste on the part of the insect for fermented juices and sap and vegetable matter undergoing the process of decay or fermentation, and it is quite possible that estates cultivated more in accordance with Nature's plans than after the methods invented by agriculturists for the increase of yield, would have less to complain about pests in general."

"Read," added Potts producing a paper from his pocket "the bulletin of the U.S. Department of Agriculture, to which Mr. E. Green drew attention, as bearing upon the Cocoa borer which belongs to the family *Scolytidae* about which the bulletin treats." Here is a notable extract from this bulletin: "As a rule, populous colonies of these beetles, and galleries so numerous and extensive as to be capable of doing serious harm, are found *only in trees which before the attack began were sick unto death with maladies for which the timber beetles are in no wise responsible.*"

"What then" said Fig "would you recommend the planter to do with regard to the suckers that invariably appear in the first few years of the life of a cacao tree?"

"If" said Potts "Mr. Martin and his friends find the suckers such a perfect substitute for the trunk after its decay and destruction, it would be well to accept with humility the suggestion made by the tree to man that it is anticipating the evil day by putting out its suckers in time. It is a method of rejuvenating itself and guarding against dissolution, that the tree has, provided for it by the greater designer.

FRUIT CULTURE. (Continued.)

THE CONSTRUCTION AND FUNCTION OF THE ROOT.

The fruit tree is fixed to the ground by means of the main root and its several branches. The root has a central cylinder of wood-tissue in which are large vessels, and round their woody cylinder is a layer of softer tissue which sheathes it completely and is distinguished at the cortex. In seedlings the outer of the root is extremely delicate, almost transparent, and absorptive of moisture. In a mature tree, however, the enlarged roots have entirely lost the power of vitally absorbing water from the soil: they collect nothing themselves, but in addition to fixing the tree firmly to the ground, conduct through their woody cylinder the fluid which has been conveyed from the soil for the use of the stem and leaves. The fluid material from the soil is then absorbed only by a portion behind the extreme end of each rootlet. This absorptive region is covered with fine root-hairs forming often a close pile like velvet, and thus enormously increasing the surface through which water can be taken in. Before these root-hairs become hard and discoloured they drop off, and the portion of the rootlet on which they grew is comparatively useless for purposes of absorption. Meanwhile, the tip of the root has pushed further into the soil; fresh root-hairs have developed on the newly-grown portion, and they in their turn fulfil the function required of them. The actual growing point absorbs but little; it is covered with a protective cup of tissue which is constantly wearing away and as constantly being renewed, so serving to protect the growing points from actual contact with the particles of the soil through which it has to force its way. Trees, therefore, which are transplanted without a ball of original earth round their base and with but few root-branches projecting below cannot immediately take anything from the soil when planted in a new spot. The first effort of life after replanting is to throw out new root-fibres, each with its protective cap to explore and forage in the fresh soil. As they elongate absorptive hairs cover the space of a few inches behind the cap and begin their functions, passing on the fluid taken up by them into the tissues of the root. As the lengthening proceeds, the hindermost hairs die off in a few days just in proportion as new ones arise behind the apex. Thus, it will be seen that the part of the root which absorbs is perpetually moving forward and coming in contact with unexhausted particles of soil instead of lying inactive among material which it has worked out. The root-hairs cling tenaciously to the particles they touch, and as it were mould themselves on them. Their moist surface is capable of disclosing traces of the mineral constituents contained therein, and the solution passes inward to the carrying system of the root. After having developed a certain number of rootlets and begun the process of absorption, the plant which may be said in the meantime to have been lying dormant begins to show signs of renewed vital activity once more.

Extreme care in lifting plants and preserving as much as possible its small fibres of the roots will repay the trouble taken. By doing this we give it

less repairs to make good. In transplanting it is advisable to use a six-pronged fork, and to avoid as much as possible any cutting action that would be caused by such an implement as a spade or "mamotie."

With a knowledge of the above facts relative to the structure of the root system of plants and the method of absorption of plant food from the soil, the coarse method of chopping young trees out with a mamotie, so that they only have a few ragged stumps left in lieu of roots will, of course, never be tolerated. Such trees, when set in the ground, will have to begin life by "callusing" the many wounds in the wood tissue of their stumps, and then sending rootlets from this callus-layer, just as if they were cuttings set so strike. Indeed, they have not even the chance that ordinary cuttings get, for the stem and its numerous buds make immense demands upon the infant rootlets, far more than they can satisfy. And thus the miserable thing languishes, makes the poorest growth above, and gets thrown back a season or perhaps more, merely for want of reasonable care in transplanting.

In a tree planted in well-tilled, well-drained, well-opened soil, the advance of the root-tips continues till the limit of the tree's requirements is reached. In general, one may say that the expanse of the foliage of a fruit tree gives a tolerably accurate measure of the root-system under ground, but obviously the feeding ground of the roots is not close to the trunk, but in a circle whose radius is never less than half the height of the tree when matured. Those who have a knowledge of the steady advance in the roots described above will not therefore tolerate for a moment the custom of applying irrigation water or manure in a hollow dug round the base of the trunk, nor will they be consenting parties to the planting of trees in the holes cut in an impervious clay of soil which has never been trenched. The normal advance of the root system, under the latter circumstances, will be stopped by the impenetrable walls of the pit, and so the tree becomes unhealthy and short-lived in spite of doses of manure and irrigation.

(To be continued.)

NOTES ON THE NORTH-CENTRAL PROVINCE.

This is a Province of tanks and ruins. In ancient times it was one of the most populous and productive parts of Ceylon; but now it is very unlike its former self. Although the largest Province in the Island, it is now the poorest in population and produce. It strikes a stranger at once that there is a large extent of waste land here; and he feels that this Province is capable of much agricultural development. The Government, well aware of this fact, have restored the ancient tanks and canals and are trying to encourage the people in the growing of paddy and other products. The water of most of the tanks contains a good deal of manurial matter in solution, and this combined with the natural rich-

* "Callusing" is the natural healing up of a wound such as is caused by cutting a part of a tree, and this is done by the tree by forming a spongy cushion of protective tissue known to gardeners as a "callus."

ness of the soil makes it possible for the goiyia to carry on paddy cultivation without any special manuring.

2. The goiyias, however, are slow to avail themselves of the facilities that have been given for cultivation. There is still a vast acreage under the tanks which can be asweddimized and converted into fertile paddy-fields. If the people of certain other parts, such as Jaffna, had as great facilities for the raising of paddy what results might we not expect.

3. These remarks apply to the cultivation of dry crops as well. The favourite form of dry cultivation with the villagers is "Chena" cultivation. But this has been prohibited, they complain, since of late. They do not, however, think of making fenced enclosures in their own compounds and growing vegetables &c. One could hardly get any vegetables in most of the villages, and even in Anuradhapura there is often a great scarcity of them.

4. Horticulture is another important branch of agriculture that is neglected in this province. Excellent fruit can be grown in many parts of it. The *Jaffna Patriot* says:—"We have heard that, in close proximity to the town of Anuradhapura, a garden of five acres cultivated with plantains only, yields five hundred rupees a year." Besides Anuradhapura and the villages adjoining it, there are many other localities where oranges, mangoes, bananas &c. thrive well. The productiveness of some of them is proverbial.

5. For instance, there is a village called Kidagolleagama which, people say, was famous for fruit and other garden produce, and was styled "Parana Matale." The groves of fruit trees that used to grow in this village are still fresh in the minds of some of the oldest residents of the place. But this village has greatly declined in its fruit and garden culture owing to the lack of interest and enterprise of the villagers. There are many other villages in which scarcely any attempt has been made to grow garden produce or even coconuts, though the soil is sufficiently rich.

6. As regards coconuts it may be said that though they do not grow here quite so well as those along the sea coast, yet they will compare very favourably with the latter. Judging from the trees I have seen, I should think that a great part of this Province will suit coconuts as much as the Pallai district. Although proximity to the sea makes land particularly suitable for coconuts, one finds that, in this Province, in moist soils which contain a fair proportion of sand, the palm thrives and bears well; and if the villagers were enterprising enough, there would be many a flourishing coconut estate in this Province now, considering the fact that coconut planting is one of the safest and most remunerative forms of investment for natives. At present, however, by far the larger proportion of coconuts required for consumption in the Province is got from places outside it.

7. The people, although they fail to make the best of their opportunities, are more to be pitied than blamed, and have to be practically taught how they could better their condition by bringing more energy and enterprise to bear upon their cultivation. Their ignorance combined with a degeneracy of constitution brought on by the two great scourges of this Province, parangi and malaria, accounts for much of the present state of affairs.

8. By the wise policy of a benign Government, things have begun to improve since of late. Parangi and fever are becoming more scarce, and the people are getting more enlightened. The Government Agent is trying to induce the villagers to improve

the state of agriculture in its various branches. One effect of discouraging chena cultivation is that people have taken more kindly to growing paddy.

9. There are three model gardens in Anuradhapura where vegetables and fruit trees are grown. One of these is under the Tissawewa and another under Basuvakulam. In these, in addition to superior native vegetables, are cultivated those English vegetables that will thrive in the low country. There are also grown, economic products new to the Province, such as the arrowroot and cotton. I noticed also about a thousand jak plants for free distribution among the villagers. It is curious to find that the jak which is a mainstay of the villagers in the Southern and Western Provinces in times of dearth and which supplies them with food all round the year, is very scarce in this Province; and the Government Agent noticing this fact and recognizing the usefulness of the tree, has got these seedlings raised for distribution among the villagers.

These two gardens were formerly in charge of Mr. Ranesinghe, Agricultural Instructor. The third one is the Botanical and Experimental Garden from which plants of economic value are given away or sold to the villagers.

10. The last item in the Jubilee programme in Anuradhapura is to be an AgriHorticultural Show which is to come off on the 26th. This, though the last, will not be the least event in the local celebration. It will give a stimulus to the goiyias to go in more largely for the raising of superior varieties of agri-horticultural products. Only exhibits grown in this Province will be received for competition at this Show, and separate prizes will be given for the best collection from each "Palata." It would be desirable to hold such exhibitions here annually.

11. But after the natives of the Province have done their best, there will be a large extent of land still left which can be converted into paddy-fields, coconut estates, orchards and vegetable gardens. Now that we are within measurable distance of the day when the railway will be extended to Amradhapura and Jaffna, it is high time for Ceylonese living in the crowded and congested parts of the South-West and North of the Island to think of coming over to this Province and opening large estates. Capitalists will find it a profitable investment.

The clearing of jungles, the drainage, &c. which the extended cultivation will involve, will help to remove the malaria and improve the health of the Province; and with the opening of new roads, the extension of the railway, and the plying of boats across the large sheets of water such as Kalawewa, Nuwarawewa and Minneriya, for carrying the produce of the villages, the North-Central Province may, at no distant date, attain to a state of prosperity which it had never enjoyed before.

12. For the breeding and rearing of cattle, sheep and goats this Province is second to no other in the Island. The fertile district of Tamankadnwa, once called the granary of Ceylon, and now the largest cattle district in the Province, affords special facilities for this purpose, as there are large tracts of rich pasturage in it.

Pony-breeding, too, is carried on to a certain extent in this Province; but, instead of the haphazard way in which this is done, if proper breeding establishments were started here as in India, importing good stallions and castrating the "weeds," both pony and mule-breeding can be carried on with highly satisfactory results.

E. T. HOOLE.

Anuradhapura, 21st June, 1897.

DISEASES OF TREES.

(MR. N. A. COTT in the *Agricultural Gazette of N.S. WALES.*)

Every year brings me a number of enquiries as to the cause of the death of the whole or parts of trees, generally fruit trees, under peculiar circumstances, such as the absence of any apparent cause, or, at least, adequate cause. Sometimes the deaths are sudden, sometimes not; but in most such cases the disease has not been prolonged. These cases must not be confounded with death from lack of nourishment or care, or from old age. A tree in good soil or hitherto vigorous, suddenly sickens and dies, or perhaps manages to hold out for a season or two and then dies; such is the typical case to which I refer.

In such instances we at once suspect one of two causes, namely, insects boring in the wood, or the presence of some timber-rotting fungus. In the former case the death of the tree or branch is often sudden. The leaves will dry up and turn brown, as if a fire had scorched them, the whole operation sometimes occupying only a few days. If a limb be cut away and split up, the boring insects are usually discovered. Their holes may usually be seen on the surface.

In the second case the death of the tree is usually slower, and the cause is commonly more hidden from sight. The wood of the dead tree, however, on being examined carefully, or compared with healthy wood of the same kind, exhibits the peculiarities well known to timber merchants and carpenters under the name of *dry-rot*. The diseased wood is softer and more brittle than sound wood, and differs also in colour, and finally becomes punk and falls to pieces. This deterioration is due to the presence among the fibres of the wood of the hyphæ or vegetative organs of a fungus whose fruit may sometimes be seen either growing out from the bark in the form of "shelves" or "brackets," or in the form of toad-stools near the base of the tree. Strange as it may seem, the microscopic "roots," as we may almost call the vegetative organs of these fungi, penetrate long distances into the solid wood of the tree, where, by gradually absorbing and changing the substance of the cells of the wood, they weaken it and give rise to the well-known appearance of *dry-rot*. The death of the whole or part of the tree follows as a matter of course.

Both these conditions may occur in the same tree, and it is therefore well to have a clear idea as possible of the external appearance due to each of these diseases.

Remedies.

1. Trees dead or dying from either of these causes should be burnt. If there is reason to attribute the death to *dry-rot* fungi, the stump and main roots should also be destroyed by fire and the ground treated with quicklime.

2. Keep the place free from rotting and decayed timber. Such only forms a nidus, from which spring the spores of the *dry-rot* fungi.

3. Where *timber-rot* is prevalent, take the precaution to disinfect with tar the wounds on trees, either those caused accidentally or by pruning. In pruning be careful to use sharp tools, and to use them skilfully, and cut off the limbs close to the

trunk or main branch that bears them, the idea being to give the tree a good chance to heal the wound as rapidly as possible.

4. Remove superfluous bark, and whitewash the trunk and main branches.

5. Where a wound fails to heal over, and becomes a sore, cut away the wood.

6. Look out that the drainage is good. This is a most important precaution against timber-destroying fungi. Damp, ill-drained plantations are their natural home.

7. As regards the remedies for borers, it is necessary to point out that they are, for the most part, totally different to the preceding ones, directed, as they are, against an insect instead of a fungus. It is when I observe remedies for fungi being applied to trees suffering from borers, and *vice versa*, that I realise how necessary it is to point out the possibility of being deceived as to the nature of diseases through resemblances in their external appearances. It is a waste of money and energy to apply the wrong remedies. It would be of little use to apply fungicides to a tree attacked by the borer alone, or to adopt the following remedies against borers for *dry-rot* fungi:—

1. Remove from the vicinity, unless they are serving some useful purpose, all native trees that are found to harbour the borer.

2. Spray the trees with tar-water, or some other substance that will be so offensive to the female that she will decline to lay her eggs there.

3. Remove loose bark, and whitewash the trunk and main branches.

4. Squirt or otherwise insert into all holes and crevices to be found, such liquids as kerosene emulsion or phenyl.

5. Set lighted lanterns at night, in the proper season, and so arrange them that the attracted and dazed moth (where the mature insect is a moth) will fly against rags and dangling strings soaked in kerosene, or some very sticky surface.

NOTES FROM A TRAVELLER'S DIARY.

(Continued.)

Again, as regards paddy cultivation, anyone who goes about the country with his eyes open cannot but be surprised at the crude methods practised by some of the villagers in the cultivation of the staple food product of the island. In Burma and other countries where rice is extensively grown and exported in large quantities, the most approved methods, such as the nursery system, transplanting, and weeding are invariably carried out, and the result is an enormously large crop, something like ninety-fold. In some of the Kandyan districts of this island the preparation of the land is apparently most carefully carried out, and weeding is also practised. These methods are, however, confined to only a very small area of the island, and the people even here have as yet to learn a great deal as regards the most approved methods of preparing the land and various other details, such as the selection of seed paddy &c.

Sir Arthur Havelock, our late Governor, speaking at a prize-giving of the School of Agriculture said: "I was particularly interested by those passages in the report of the Superintendent which deal with

the results of experiments in the improvement of paddy cultivation. . . it is pitiful to hear of the results of the general run of paddy cultivation in this country. One sees an immense amount of time, labour, and patience expended in cultivating those fields, and the result, we are told is very often of the poorest description, far behind the result of the paddy cultivated in India or Burma. In certain portions of the Colony in which I have ridden about, I have made a point of trying to discover, from those who were with me, what was the yield of the fields through which we had been passing. I have often seen fields most beautifully cultivated, there being most painstaking arrangements for irrigation, for damming water, for ploughing, and for every other possible item of cultivation, and I have been told that probably the results may be six-fold or four-fold. I have it on the authority of one of our Government Agents that in his province there are many fields which do not yield more than five-fold. The work of this institution therefore in promoting the improvement of paddy cultivation is, I suppose of all its various works, the most important and the most practical. For that reason I am particularly glad to hear of the satisfactory results that have been attained, and I can only hope that by every possible expedient, by the introduction of new forms of cultivation, and by the importation possibly of new kinds of paddy seed, the work of the College will profit the country."

Mr. H. W. Green, the founder of this institution, who had always been a keen observer of the various methods of cultivation as practised in the country, on some occasion spoke as follows:—"His Excellency had remarked on the absurdly and lamentably low yield of paddy. It was absurd and it was lamentable. He had also remarked on the beautiful cultivation of the fields and irrigation lands. If it were no heresy, might he (the speaker) say that it was beautiful on the outside, that everything except the first step was beautifully done. It was like the house built on sand that we read about in a certain old book. The house might be beautiful, but there was no foundation. The Sinhalese cultivator and the Tamil cultivator in some districts—not in Jaffna and districts where water was scarce, but wherever water was plentiful—was inclined to begin at the top without the bottom. He forgot that, however bountiful nature might be in giving him rain or tanks for irrigation, he must prepare the soil for the water. He began to prepare the soil with the water on it. He said this method killed the weeds, and if he spoke the truth he would also say that it saved trouble; but he should plough the land when it was dry, turn the whole thing over and leave it to the baking of the sun for two or three months before the water and the beautiful cultivation came on. That was the one sole foundation fault of paddy cultivation in this country."

I quote further from Mr. Green's speech:—

"Wherever the experiments taught at that school had been tried honestly—they had always been honestly tried—it had been found that where the land had been thoroughly turned up and prepared, they had at least double the crop of their neighbours, and often more than double. If

the people would only work carefully, there was no reason why we in Ceylon should not have the Burma yield. The climate was all right, everything was all right, but they did not prepare the soil for the working of bountiful providence." Again Mr. Green says: "That his primary object in starting the school was to help small agriculturists, and not the big ones—small owners of little tracts of land who suffered distress from want of food—that want of food he had seen, and he was satisfied that it was caused by the people not knowing what to do with what they had. They threw away 3 bushels of paddy in sowing when 10 seers would be enough, and this saving of seed paddy would keep a family in comparative comfort for a month or 6 weeks, and that in a time of famine and distress was a great thing."

On the face of what has so far been said regarding the cultivation of paddy in this island, it is impossible to deny that there is a great deal to be taught to the villager in this branch of agriculture. A few of the students trained at the school were sent out to the country expressly with the view of showing improved methods of paddy cultivation to the villagers. The experiments conducted by these young men from all we gather from records, have been in almost every case a very great success, and the villagers have in some instances learnt much from them. But in a country like this, where the people are so conservative, it is impossible to create a lasting impression upon them by experiments conducted in a haphazard manner here and there. A series of experiments for a great length of time at each place and under proper guidance should have been systematically carried out. Unfortunately, this has not been done. Young instructors were in most cases placed under the guidance of the native chiefs of the districts. These chiefs have not received any training in agriculture, and they themselves are as ignorant as the ordinary villager in these matters. Mr. Elliott, late Government Agent, speaking at a prize-day of the School of Agriculture explained the true position of the instructors in the following words:—"They had heard of what was doing within these walls, but he could give some account of what former students had done elsewhere, especially in the Eastern Province. He had had their co-operation in several of the agricultural experiments, and was happy to be able to testify that they were all a credit to the school in which they were trained. They were capable agriculturists and intelligent workmen, who understood their work, and knew how and when to plough, to sow, to water and to reap. They were, however handicapped in their work and were rather expected like the Hebrew of old to make bricks without straw. They had no money, no seed paddy, no implements given them, but were generally attached to an ordinary village school and expected to cultivate paddy in an improved style. Progress under such circumstances, was difficult, and their motto must be taken from the tortoise rather than the hare—"slow but sure." The Hon'ble Mr. Mitchell, Mercantile Representative of the Legislative Council, has expressed the following opinion:—"With regard to the good the school was doing nobody could be blind to that. Lads came from the country and studied agriculture there, and went

back to their villages or other Agricultural Schools, and no one could be blind to the fact that very important results must follow from that in the course of time."

TRAVELLER.

(To be continued.)

POTASH MANURES AND THE NEED FOR SPECIAL POTASH FERTILIZERS.

(Continued.)

The great source of potash manures are the Stassfurt deposits. Ever since the beginning of last century the district of Stassfurt, in the province of Saxony, in North Germany, has been well known as the centre of a large salt industry. The salt was formerly obtained by pumping up liquid from wells, and evaporating it in pans. The discovery of solid rock salt had the effect, however, of soon rendering this industry non-lucrative; and hence, in the year 1839, the Prussian Government instituted a series of investigations for the purpose of discovering whether rock salt could not be found at Stassfurt. At first the attempts were unsuccessful, but in 1857 a stratum of rock salt was discovered about 1000 feet below the surface. This deposit lay below a large layer of what were called Abraum salts (refuse salts), which consisted of compounds of potash and magnesia. For a number of years little value was attached to these deposits, as their importance in agriculture at that time was not known. After a time, however, potash began to be extracted from these salts for use in various chemical manufactures. The value of potash as a manure for farm crops was also demonstrated by the researches of Liebig, and its employment for this purpose became more and more extensive with the lapse of time. At the present time the potash industry in Stassfurt has reached enormous dimensions, and every year the amount of potash exported thence to all parts of the world for fertilising purposes is steadily increasing. Stassfurt has now become the centre of one of the largest manufacturing industries in Germany, and employs about 10,000 operatives in connection with potash mining and manufacture in Germany. Not much short of two million tons of Potash Salts are annually produced in the Stassfurt districts.

It is believed that these salts were formed by the partial isolation of a sea, the waters of which still maintained communication with the ocean for a long time, by means of small channels. This was thousands of years ago, and the climate of that part of Europe was then more of a tropical nature than it is at present. The result of these conditions was the steady evaporation of these partially isolated lakes of salt water, and the constant accumulation of the salt deposits. The less soluble salts were first deposited, such as sulphate of lime, and in this way the lowermost layer of the deposit, which consists largely of this substance, was formed. Above this was deposited the rock salt. This stratum, which is about 3,000 feet deep, is estimated to have taken 13,000 years in its formation. In the upper regions of the deposit lies the potash layer, consisting largely of a mineral known as carnallit, which consists of muriate of

potash and chloride of magnesia. This deposit is from 50 to 130 feet thick, and is the chief source of the potash salts. Above the potash there is a layer of impervious clay, which serves a very useful purpose in protecting the carnallit from being dissolved by the water, which would otherwise have been constantly percolating down through the soil; indeed, had it not been for this layer of clay, it is highly probable that the potash, as well as the magnesia salts, would long ago have been washed out of these deposits. Above the clay lies another stratum of anhydrit, and above it a second salt deposit, which is of very much more recent formation than the first, and is characterised by its great purity.

The enormous extent of these deposits may be estimated from the fact that their total depth amounts to about 5,000 feet, or nearly a mile; while the deposits extend over an area of several thousand square miles directly east of the Harz mountains. Here and there, irregularities occur in the sequence of the different deposits. At some places surface water has entered, and, by its solvent action, dissolved out certain of the potash compounds, or changed them into other compounds. Hence, there occurs throughout the surface, deposits of such substances as kainit and sylvinit, both crystallised salts of potash, the former made up of a mixture of the sulphate and chlorides of potash and magnesia, and the latter of a mixture of muriate of potash, rock salt, and kainit. The extent of these deposits is so vast that they may be regarded as practically inexhaustible, or, at any rate, as sufficient to supply the world with potash for many generations to come.

In Germany, quite a number of the raw potash salts are used for manurial purposes, as they can be obtained very cheaply; but the more concentrated salts are preferred for export, owing to the greater relative expense incurred in the freight and handling of the impure forms. The chief amount of potash exported is in the forms of the refined potash salts, viz., muriate and sulphate of potash, and in the less pure form of kainit. The composition of some of the more commonly occurring crude potash salts is, however, deserving of notice.

Carnallit, which is the most important, contains about 26 per cent. of muriate of potash. It is found of a variety of colours, caused by the admixture of such impurities as iron, clay, and organic matters; and may be white, yellow, red, violet, grey, or even black. It is hardly ever found in the pure condition, and, as mined, generally contains only about 60 per cent. of carnallit, the other 40 per cent. being made up chiefly of rock salt, kieserit, anhydrit and clay. It is sold for agricultural purposes in the form of a powder, and is guaranteed to contain at least 9 per cent. of potash, equal to about 14 per cent. of muriate of potash.

Kainit, like carnallit, is found of a variety of colours, and never in the pure condition; but contains more or less rock salt and other impurities. As sold for agricultural purposes, it is usually guaranteed to contain 12½ per cent. of potash.

Sylvinit is the third crude salt, and contains, on an average, 22 to 30 per cent. of muriate of potash. It thus sometimes contains more potash than kainit.

All these crude forms of potash are extensively used, and are most suitable for the districts adjacent to the mines, or to which there exists convenient and cheap transport. Where the cost of carriage is considerable, the refined and more concentrated potash salts are more suitable, and if account be also taken of the relative expenses of cartage and labour, their use is generally found to be considerably economical.

The salts are made of various qualities and are chiefly prepared from carnallit. The method of preparation is as follows:—The carnallit is agitated with water in large tanks with the result that it is decomposed into a magma of finely-crystallised muriate of potash and a solution of magnesium chloride. The solution retains very little muriate of potash at a low temperature, and where the proportion of magnesium chloride does not exceed three times of the muriate of potash, the remainder of the muriate is deposited as crystals on further heating and cooling. The fine crystals of muriate of potash are further dissolved and purified by crystallisation.

Muriate of potash as sent into the markets and used for manure is usually guaranteed to contain from 82 to 90 per cent. of muriate, equal to about from 50 to 58 per cent. of potash. Two classes of sulphate of potash are also sold, viz., what is known as high grade sulphate containing 92 to 98 per cent. of the sulphate and equal to 50 to 53 of potash, and low grade sulphate containing 50 per cent. sulphate equal to 27 per cent. potash.

INSECT PESTS.

(Continued.)

For almost every insect there is a remedy; the question generally is one of applying. There is no sovereign remedy for all insects; for some insects, and important ones too, there is no economical remedy; but there are certain general measures which if faithfully carried out will largely decrease loss from insect attack. The most important of these is clean culture and high culture.

A great many insect pests lie dormant in cultivated lands at certain seasons finding shelter in old stubble, stalk, leaves and other rubbish found on the land. From such places they come forth at other seasons and ready to carry on their destructive work on vegetation. Obviously, much benefit would here result from clean culture. The gathering of all rubbish, dead vegetable matter, and other refuse, and having it burned or properly composed would destroy an immense number of these insects. Diseased branches of trees should also be burnt and the trunks and branches of standing trees kept free of moss, lichens and rough bark, beneath which insects or their eggs are harboured. Weeds and foreign growth should not be tolerated along fences, walls or hedges. Clean culture is the stitch in time to save nine.

High culture is almost equally important in warding off insect attack or rather in enabling the plant to overcome it. While the plant which is weak and sickly through lack of proper cultivation or needed fertilizing material in the soil succumbs to the attack of insects, the plant which is properly cultivated is often able to overcome the

attack and mature in good condition despite the drain upon its vitality. Particularly is this true of vegetables.

Fruit trees kept in vigorous growth may scarcely appear to be affected by infesting scale insects, while trees poorly nourished and uncultivated are found losing vitality along its branches when attacked to a like extent. Some insects also show a decided preference for plants making only a feeble growth, and many writers on entomology assert that certain insects never attack a plant unless it is in an unhealthy condition. The second great principle in preventing insect injury is, then, keeping the crops well fed and properly cultivated.

In addition to the measures already noted, the judicious agriculturist will, whenever possible, make a judicious rotation of crops to repress insect ravages. Many insects, as well as diseases, are kept down solely by this means which is economy for other reasons as well. Such insects being capable of subsisting only on a certain plant or class of plants, are destroyed by starvation when the soil is used for the growth of other plants.

[In the case of permanent forms of cultivation the nearest substitute for a rotation of crops is, as we have previously pointed out in these pages, mixed cropping.]

But many insects cannot be controlled by these general methods of culture and need to be dealt with by more artificial means. Much attention has been paid to such means within the last generation, and several very valuable insecticides have as a result been brought into common use. It is the duty of the agriculturist to be acquainted with the best of these insecticides and find out for what they are applicable, since an insecticide that answers perfectly for one insect may be totally inadequate for another.

In general insecticides may be divided into two classes: those which kill by contact and those which kill by internal poisoning. For the judicious use of both kinds it is important that we should recognise that insects are also divisible into two large groups according to their method of taking food. One class of insects, which embrace locusts, caterpillars and beetles, takes solid food by means of biting jaws, while the other which embraces bugs, scale insects, bark lice and the like, takes only liquid food imbibed through a proboscis. Insects of the first kind can be disposed off with tolerable ease by applying poisons such as arsenites to their food, while insects of the second type are clearly beyond the reach of such poisons. Their method of taking food affixes them more or less permanently to the surface they are on, and through which they suck in their food, so that they are vulnerable to penetrating insecticides such as kerosene emulsion which further close up their breathing pores and thus suffocate them.

SOME CROP NOTES.

Onions.—Onions do best upon a light, loamy soil, and one that has been kept free from weeds by careful cultivation. They can be grown for a number of years on the same land if properly fertilized. Onions thrive well on soils which contain much humus, and which is consequently retentive of moisture. It is well to have onions preceded

by a crop which is calculated to free the land of weeds. Onions need lime for their development, and to make good crops they require heavy manuring. Commercial fertilizers are better for onions than animal manures, since the former contain no seed-producing weeds. About 1,500 lbs. of a fertilizer with the essential ingredients in the following proportions is recommended:—

Available phosphoric acid, 6 per cent ; potash, 7 per cent ; and nitrogen, 4 per cent. One practice in planting is to use sets or small bulbs grown the previous year from thickly-grown seed ; but good crops can be raised from the black seed by sowing early. Stable manure is objectionable for onions for the reason that it fosters the onion maggot. On rich humus soils, a maximum of phosphoric acid and potash should be applied, and only a small quantity of nitrogen. Too much nitrogen is also objectionable, as it retards the ripening and curing.

Tomatoes.—Tomatoes prefer a light, warm soil though it thrives in other soils as well ; the latter situations help in the production of early fruit, while heavy soils produce late fruit. A good substantial manuring should consist of about 1,200 lbs. per acre of a fertilizer containing : available phosphoric acid, 7 per cent ; potash, 6 per cent ; and nitrogen, 4 per cent. The tomato needs a good supply of readily-available nitrogen, but besides this good supplies of phosphoric acid and potash are required.

The best plan is to sow the seed in shallow boxes in a warm situation. As soon as the plants have developed the second set of leaves, transplant them into other boxes a little deeper and put the plants about two inches apart. If they could be again transplanted two or three weeks before sowing and put about four inches apart so much the better. Care should be taken to gradually expose the plants more and more so as to harden them to the open air and make them stout and short. Plants treated in this way could be set out with ease and come into fruit a month or more sooner than those sown in the open air. In field culture the plants are set four by five feet apart, but in gardens where room is scarce it is well to train them up in some manner, and for this purpose galvanized wire netting fastened to stakes is best used. Where there is plenty of room larger crops can be had by allowing the plants to fall on the ground, but keeping the fruits off it. Where tomatoes are affected by blight, spray with Bordeaux mixture.

[*Bordeaux mixture for Tomatoes* :—Take 2 oz. of sulphate of copper (blue stone) and dissolve in half a gallon of water in one vessel, slake 2 oz. quicklime in another vessel forming it into a thin white wash. Pour the milk of lime into the sulphate of copper solution slowly through a hair sieve, then add enough water to make up 3½ gallons ; stir well and apply to every part of the plant, coating them evenly with the thinnest possible film of the mixture. It will not injure green fruit for use, but those near ripening should be cut, as it is not desirable to use the mixture over ripening fruit. The lime should be quite fresh and the blue stone pure.]

GENERAL ITEMS.

In a bulletin issued by the Department of Agriculture, N. S. Wales, the following measures are recommended for wood borers : Inject turpentine or oil into the hole ; cut off infected limbs and burn and destroy perfect beetles whenever seen.

In Bulletin No. 13 of the Department of Agriculture, Brisbane, Mr. Albert Benson writes as follows with reference to insects boring into the roots, stem or branches : These are true boring insects, and are usually the larvae of beetles of various kinds. Some of these beetles are leaf-eaters, and can be destroyed by spraying with Paris green ; others, again, can be destroyed by placing a cloth under the trees and then giving the branches a few sharp raps, when all the insects will fall to the ground, and can be swept off the sheet and destroyed. When the insects are in the larval or borer stage, if they are of large size they can be killed by inserting a fine pliable wire into their burrows, or by injecting a small quantity of kerosene or turpentine into their burrows, and plugging up the outlet with a piece of soft wood or clay. In any case when borers are at all troublesome, the mature insect (generally beetles) should be destroyed whenever and wherever they are found.

We take the following remarks with reference to Agricultural Shows from the *Cape Agricultural Journal* :—That Agricultural Shows should be held with a two-fold purpose is not often as much considered as it ought to be. As a means of affording a vast amount of useful information to the farming community, there can be no doubt that agricultural exhibitions are excellent institutions. The concentration of a large number of high-class exhibits in some populous centre, and the keen competition that takes place in the various classes, must necessarily serve an important educational purpose and furnish reliable mediums for imparting useful practical knowledge. If Agricultural Shows are to be conducted in such a manner as not to serve an educational purpose, then they become *worse than useless*. To be both useful and instructive they must be conducted in a manner that the largest number of varied exhibits possible will be brought together in competition for prizes. If we really believe in the utility and value of the educational side of the Show, then every facility should be given and efforts made to render the suggestive information of the Show easily available, especially in the interests of any young farmers and men who have not many like opportunities.

Professor Wrightson in his paper, contributed to the Journal of the Royal Agricultural Society, on "The Agricultural Lessons of 'the Eighties'" says :—Of this we may be assured, that one of the greatest lessons taught by the eighties is the necessity of the systematic instruction in Agriculture in all its branches.

In the year 1895, the mean rainfall for the whole of England and Wales was 29 in., for the whole of Scotland 39·7 in., and for the whole of Ireland 36·8 in. The averages for the last thirty years are for the three countries respectively 32 in., 40·4 in., and 39·4 in.

[No. 2.

“PIONEERS OF THE PLANTING ENTERPRISE IN CEYLON.”

(*Second Series.*)

REGINALD BEAUCHAMP DOWNALL,

PLANTER AND M.L. C.—1863—1888.

LEAVING England early in 1863 by a sailing-ship, R. B. Downall arrived in Ceylon during May following, after the long voyage via the Cape of Good Hope. He was at once posted by Messrs. George Wall & Co., as assistant to the late Watkin William Wynn on Kent and Ambokka estates, Matale West. He was the son of Archdeacon Downall of Okelhampton and we recall the fact of a local Devonshire paper being sent us by an ill-natured friend, in which the fond father had rather foolishly published long extracts from his young son's letters, never meant for other eyes than those of the domestic circle, while he wound up with the statement that his son had qualified both in Bookkeeping and in the Tamil language on the voyage, so that he was at once put into a responsible charge as manager of a plantation on his arrival in Ceylon! We took care at the time, that no extract was made from the innocent communication into the *Observer*. The Archdeacon—who was greatly attached to his Ceylon son—died in 1872; and Mrs. Downall and daughters then retired to Barley, near Exeter, which was Mr. Downall's home in England till his mother's death.

Mr. Downall did not long remain an assistant on the Matale estate; for, in our Directory of 1864-5, we find him transferred to Dolosbage as manager of Kalugalla estate, and with that, we

believe, he combined a certain proportion of duties as Visiting Agent or Inspector of Estates—an unprecedentedly early appointment. A little later we find Mr. Downall a full-blown Visiting Agent, residing at Peradeniya and representing Geo. Wall & Co.'s firm in Kandy. This continued—with the exception of a holiday trip to England—up till 1874, when we find, still as Visiting Agent and Justice of the Peace, Mr. Downall occupied Barnes' Hall, Nuwara Eliya, where he continued up till 1877 or so. Then came his purchase of Mr. G. A. Critwell's plantations and Mr. Downall went to reside on Daumbatenne, Haputale. In 1876 Mr. Downall was, for the first time, elected Planting Member of Council, a post which he vacated on going home in 1879, to resume it again on his return the next year; but he once more retired in 1882 to have a brief spell at home; but again resumed in 1885 and continued in that honourable and onerous post until his final retirement from the island was compelled by fatal illness in 1888.

Such is the briefest possible summary of Mr. Downall's public career in Ceylon. To fill up the details and before going into particulars with which we are more especially acquainted, we have been favoured with two accounts by old and dear planting friends who knew him from the outset of his life in Ceylon to his sadly premature end. First, we have that of a gentleman, who was like a brother, his family and that of Mr. Downall being friends at home, and

as both the young men started from England about the same time—Mr. Downall leaving a month earlier but arriving a month later, because his friend came overland—there was always a friendly rivalry as to how the two “boys” were getting on. The following was written for us to use with our own notes, but amalgamation would spoil all its freshness and we trust we may be pardoned by the writer for giving the contents of his MSS. separately and *verbatim*:—

“It was either in February or March 1863 Downall left England in a sailing ship bound for Ceylon ‘round the Cape,’ and reached Colombo at end of May or early in June: he was accredited with letters of introduction to the late G. Wall—amongst several others—and Wall sent him up to Matale as assistant to W. W. Wynn.* ‘Dick Mackay,’ who resided in ‘Jolly’s Bungalow’ overlooking the Kandy lake, was then Visiting Agent to Geo. Wall & Co., and was evidently so much struck with Downall, that not only did they become great personal friends, but on Mackay’s leaving for England 18 months after Downall’s arrival, he so strongly recommended the ‘youth’ to Geo. Wall that the important post of Visiting Agent was offered to him. Well do I remember his telling me about the offer, and his asking my advice as to his accepting it. Although I had had a month’s start of him in planting, I replied that I certainly could not accept it, as I did not feel competent, but that that was no reason why he should not. However, accept it he did, and if there have been better V.A.’s in Ceylon I have not come across them! His taste for sport soon showed itself, and in 1865 he took over from William Taylor—then of Dolosbage—the following hounds:—Bluebell, Bashful, Moone-

* Mr. Downall’s first, and only, “Periya Durai,” Mr. Wm. W. Wynn, was himself an old, esteemed and notable planting Colonist of the well-known Welsh family of his name. We met him first in the “sixties” on the Borders Estate, Matale, and we are tempted to quote from a letter written after retirement with reminiscences of his Ceylon days:—
“Myddleton House, Monmouth, England 19th June 1894.

“Dear Mr. Ferguson,—The last time I saw you was in your office in Colombo in July 1889, when I called to wish you goodbye on the eve of my leaving for the old country after an *unbroken residence* in Ceylon of 43 years. And here I am now as hearty and strong as ever, and able to enjoy a day’s fishing, of which I get plenty and good. It occurs to me at this moment to ask you if you remember ‘the first time we met,’ the *when*, and the *where*?—The *where* I well remember, but the *when* ’tis so ‘long, long ago,’ that I have forgotten quite. The *where* was at good Abercrombie Swan’s Bungalow, *The Borders*, and I daresay you remember how his gallant army of sepoy’s charged down upon us, with fixed bayonets, when we were standing on the Barbecue, and how we took refuge *under the stove!*

“Most extraordinary weather, 19th June, and no Summer yet—not even one Summer’s day. With kind regards,—Yours very truly,
WATKIN WM. WYNN.”
Mr. Wynn died last year (1896) at Monmouth.

andy, of course a great favourite with the ‘dog boy,’ and also Sailor and Fly, a pair of Kangaroo hounds purchased in Colombo. The nucleus of a pack was thus started in partnership with C. Fetherstonhaugh, who kept them on Kirkoswald: then under the guidance of that cheery and most hospitable planter James McDonald. The mysteries of ‘clk hunting’ were soon acquired. In addition to hunting on Bogawantalawa and Bopatalawa, and afterwards in Nuwara Eliya, our friend seldom lost an opportunity of visiting the ‘lowcountry’ in pursuit of big game after which he met with a very fair share of success. Indian jungles, he also visited, and scored his ‘tusker,’ in company with T. S. Dobree. During his sojourn in the East he also went in pretty heavily for horse-racing, both in Ceylon and India. Perhaps of all the horses he ever raced ‘Grandmaster’ was his favourite, and he was only once beaten and that was at Peradeniya, where with a crushing weight, he was kept a little too much in the rear to allow of his ‘getting up’ when the ‘pinch’ came. I think Tom Reynolds* was about the first to take in the situation, and I can hear *now* the shout Tom R. gave ‘Grandmaster has shot his bolt’! and so the good horse had. I forget the name of his favourite Arab, a rare good one, and of which he was so fond that he shipped it home to improve the breed of the Exmoor ponies.

“R.B.D.’s first venture in coffee was ‘Middleton,’ in Dinbula, for which I think he paid £2,000—no trouble about ‘exchange’ in those days when all was £ s d.—and a right good purchase it proved.† Then in time he became the proprietor of Cruwell’s Haputale places—now Lipton’s—which also did well for him so long as coffee remained ‘King.’ His worst purchase was Monaragalla (or Monarakanda) which practically ruined him, for with the exception of the bumper crop it gave the year of his purchase, it simply absorbed all the annual profits of the other Haputale estates to keep it agoing. Few have met with a greater variety of the ups and downs of life, of sport, of success, than he of whom this is written. At one time he could have

* “Tom Reynolds,” well-known in those days and for years afterwards, as “T.K.” which came to him in this wise: a group of friends were critically examining a newly imported Australian horse, branded on the near shoulder “T.K.” when some one said what on earth can T.K. stand for? “Why, Tom Reynolds begorra!” says Tom Reynolds in a brogue, you could knock clumps out of with an old mamotie!

† Mr. Downall’s favourite manager at this time and for many years was Mr. H. G. Mackenzie who was as much attached to, as he was trusted and liberally treated by, one of the best employers and proprietors in the long list connected with Ceylon.—Ed. T.A.

cleared out of Ceylon with at least £100,000 to his credit; but it was not quite enough, so he stuck to it a little longer; and like a great many others, a little too long for coffee, and yet not quite long enough, for tea; but he was fighting against adversity as pluckily as any one ever did, and was on the right road to 'pull round,' when he was overtaken with the incurable disease which handed our good friend over to the 'majority' on 5th Dec. 1888."

We have been favoured with another account which we think ought also to be read by itself without incorporation in a general memoir as was meant by the writer when, on boardship, he dashed off the appended interesting notes of his dear friend of long-standing at our request. This gentleman shared bungalows with Mr. Downall for many years:—

"I first met R. B. Downall early in 1866 on my return from England, when I went to live in Kandy. He was then living at Peradeniya bungalow on the old sugar estate, which continued to be his headquarters till he went to reside at Barnes' Hall, Nuwara Eliya. I believe he arrived in Ceylon in 1863 and commenced life as a coffee planter under W. W. Wynn on Kent and Ambokka estates in Matale North. Whilst he was there he and Wynn made one or two shooting trips to Kanthalai tank on the road to Trincomalee which he never forgot. After leaving Kent and Ambokka I believe he for a short time took charge of Kaloogalla estate in Dolosbage when George Wall appointed him his Visiting Agent, and he was acting in that capacity when I first met him in 1866. When not visiting, he used to attend G. Wall & Co.'s office in Kandy daily. Although he had been a planter such a short time (only two or three years) Wall discovered his ability and appointed him his Visiting Agent. Though Downall's practical knowledge at that time was limited, he did all his work most thoroughly and conscientiously, and was most particular in seeing that no unnecessary expenditure was incurred on any of the estates he visited. George Wall had the greatest confidence in him, and Downall gained experience rapidly. In 1866 he owned half of Middleton estate, Dimbula, with Elliott, and he subsequently purchased Tangakelle I think in 1869? In 1877, he sold these estates and purchased Dambattenne and Lemastota in Haputale from Crüwell, also Barnes' Hall, and soon afterwards Monerakande estate from J. T. White and H. Bois. From that time coffee in Haputale began to decline, and poor Downall died hopelessly involved. He had paid much too large a sum for Monerakande estate. If he had been

content with Dambattenne and Lemastota, he might have pulled through. During the last two or three years of his life in Ceylon he gave up Barnes' Hall, Nuwara Eliya and went to manage his Haputale estates and lived first at Monerakande and afterwards at Dambattenne. I stayed with him two or three times at each bungalow. On the occasion of my last visit I met him at the top of Dambattenne, (having crossed over the ridge from Nayabedde). He was superintending a large gang of coolies cutting out young coffee to make room for tea, and expressed his doubts as to whether he was acting wisely or not! At that time the coffee was suffering from green bug as well as leaf disease.

"In 1868 I went to live with Downall at Peradeniya and we lived together till he went home in 1870, when he left me his power of attorney. We were both fond of animals, and at one time we had two small elephants, besides elk, spotted deer and other pets. One of the elephants Downall brought up from Hambantota after a shooting trip, having shot the mother. When he went home in 1870 it went to the Kandy Temple, and it now takes part in the Perahera every year. It is a female. The other small elephant, which was given to us by Capt. Rudd of the 59th Regiment died soon after it was sent to the Dewa Nilame with the other one. Downall was very fond of sport of all kinds. He had taken to racing when I first knew him in 1866, and he was then part owner of 'Grandmaster' one of the best horses that ever came to Ceylon. Downall continued to keep race horses up to a short time before he died. He was also fond of cricket and used to take part in the annual cricket matches at Kandy from 1866 to 1870, viz., Keir, Dundas & Co. (captained by W. Martin Leake) against the World. He afterwards started a cricket club at Kandapolla, Haputale, and took great interest in it up to the time of his death. He took several shooting trips after big game both in Ceylon and Southern India. He was far from well when he went on his last trip to Travancore and never recovered. When he lived at Barnes' Hall, Nuwara Eliya, he kept a pack of hounds and gave excellent sport to his numerous friends.

"In 1876 he succeeded me as representative of the planters in the Legislative Council, and continued to represent the planting interests on and off up to the time of his death. He rendered most valuable services to the planting community in the Legislative Council, especially in respect to railway extension to Haputale. He spared no pains nor trouble in pushing forward any good work and in making sure of his facts. He was very independent, and his opinion always

carried great weight. We served on the Haputale Railway Extension Commission together.

"On the 6th August, 1888, I received a telegram from Downall from Marseilles at Freshwater asking me to meet him at Charing Cross that evening. I did so. He could scarcely walk. I got him to Long's Hotel, Old Bond Street. All the doctors he wished to consult were out of town, it being August when doctors take their holiday. I went to Sir Joseph Fayrer, he did not go out, but he recommended me to call in Dr. J. Anderson who attended Downall up to the last, and a great friendship sprang up between them. On the 7th August, Downall was removed to a private hospital, Fitz Roy House, where he underwent a most serious and painful operation which, however, did no permanent good. On the 16th October, 1888, Downall was removed to his sister's house at Flax Bourton, near Bristol. I saw him off at Paddington. He was almost in an unconscious state. He died on the evening of 5th December, 1888, at Flax Bourton, and his remains rest in the pretty little churchyard there. We were always more than ordinary friends, and I was with him as much as I could be during his last illness. He died of *cancer* in the stomach."

We can add little to the above extremely interesting details of the late Mr. Downall's personal life and sporting and planting career in Ceylon. We first came into close contact with Mr. Downall when he entered the Legislative Council, although we knew him as an occasional contributor to the *Ceylon Observer* before then. We very speedily recognized the single-mindedness of purpose and devotion to duty of the new member, and he having become a Haputale planter in 1877, entering into "the shoes" of Mr. G. A. Crüwell, we found little difficulty in interesting him in the agitation for Railway Extension from "Nawalapitiya to Haputale," which we had personally initiated in 1872, and in which we had the cordial support from the outset of Messrs. C. Tottenham and G. A. Crüwell. All through the administrations of Sir James Longden and Sir Arthur Gordon, Mr. Downall did yeoman service in Council in the cause of Railway Extension, while not neglecting his other duties as Planting Representative. In the first place we fought together during the closing term of Sir Wm. Gregory's administration and the early years of Sir James Longden's rule, to secure, if possible, sanction for one contract from Nawalapitiya to Haputale. But it was after the decision to cut the line in two and extend only to Nanuoya that the real struggle took place, in which Mr. Downall, as chief of the Uva Planters and M.L.C., bore a leading part. Here, for instance,

is a very brief *resumé* from the record of these years of hard work:—

1879, Oct.-Dec.—Agitation renewed in Legislative Council for Extension to Haputale, by Mr. Downall in what became an annual motion every session up to 1886-7; Mr. Ramanathan cordially supporting the proposal until he recanted early in 1886.

1880.—Memorial from the Haputale Planters to the Governor; and general appeal (Dec. 7) from inhabitants of Uva to the Secretary of State, Lord Kimberley.

1880-1881 and 1882 employed in trying to urge on Sir James Longden and to get sanction of Secretary of State.

1883, Dec. 29.—Full letter (with Map) from A. M. & J. Ferguson to Sir A. H. Gordon, on his arrival, reviewing the position of Railway Extension to Uva.

1884, June.—Interview of Mr. J. Ferguson with Hon. Robt. Meade at Colonial Office to urge the sanction of Extension to Haputale.

1884-85.—Waiting for Sir Arthur Gordon to make up his mind—which he did by 1886

1886, Feb.—Ceylon Agricultural Association opposes and memorializes against Railway Extension to Haputale. Mr. J. Ferguson publishes a series of letters in a pamphlet on Uva, in reply.

1886-7.—Period of strong Despatches, Uva Memorials, and much local agitation, in which Mr. Downall bore a leading part, for Haputale Extension.

1887, March 29th.—Trenchant and long Despatch of Sir A. Gordon to Sir H. T. Holland confuting Mr. Stanhope's Despatch of January 7th, 1887.

1888, March 20.—Sanction of Haputale broad gauge Extension received by Sir Arthur Gordon in Colombo, Sir H. Holland's Despatch being dated Feb. 20th.

One of Mr. Downall's best efforts in Council on behalf of the Uva Railway was in 1879, and his speech on that occasion covered nearly 5 pages in the close type of "Hansard." He was supported by the whole of the unofficial members, and both the Governor and Colonial Secretary spoke accepting the motion.

In connection with this memorial notice we have been turning over many old papers and much correspondence, and as evidence of Mr. Downall's heartiness and earnest desire to see the great work completed, we think a few of his letters may be given here. First, however, we may quote from the proceedings of the Haputale Planters' Association of which Mr. Downall was a leading spirit in September 1884; we had just returned from the old country where we had done all we could to restore confidence in the Ceylon planting industry, and to influence officials in favour of the Uva Railway. Accordingly, the Haputale P. A. on 26th September carried the following resolution:—

"That this Association do record its appreciation of Mr. John Ferguson's letters to the English papers with reference to the planting interest, and that the Secretary be requested to convey the thanks of the Association to that gentleman for the same."

This was followed a few days after by a letter from Mr. Downall:—

"Moonerakanda, Koslanda, 1st October, 1884.—My dear Sir,—I am very pleased to be able to welcome you back. I must thank you for the handsome edition of your book which arrived safely at Barley; also I fancy I have to thank you for a copy of 'The (London) Times' containing your letter (on

Ceylon Planting affairs and Railway Extension) which I read with much interest.

"We must work away again at the Railway Extension. We may yet get it I think. My idea is an Extension on any gauge that may be feasible. I have not as yet had any conversation with the Governor on the subject. I may be in Colombo about the end of the month, and shall hope to see you.—Yours truly,
R. BEAUCHAMP DOWNALL."

An interval of a couple of years of hard fighting in Council and the Press followed, and to show that Uva planters were not uninterested, we may give the following, not published before:—

"Badulla Planters' Association, Badulla, 20th Sept., 1886.

"Messrs. A. M. & J. Ferguson, 'Ceylon Observer' Office, Colombo.—Dear Sirs,—I have much pleasure in forwarding copy of a resolution passed at a General Meeting of this Association held in Badulla on Saturday the 11th September current.—I am, yours faithfully,
ALEXANDER T. RETTIE, Secretary.

"Copy of resolution referred to:

"Resolution proposed by R. P. Macfarlane, Esq., seconded by A. T. Rettie, Esq., and carried with acclamation:—'That this Association desires to express its deep sense of the exertions made by the 'Editors of the "Observer" in the cause of extending the Railway to the Province of Uva, and more especially the late exertions of Mr. John Ferguson to whom this Association desires to express its best thanks.'—A. T. R.*"

Still, there were two more weary years to follow—the more trying, because of "the split in the camp" which sent a number of the Badulla planters especially, after a narrow gauge to which Governor Gordon said at once he would be no party under any circumstances,—that is so far as to break gauge at Nanuoya. So decided an expression of opinion on the part of the Governor settled the matter in Mr. Downall's judgment, and he and the *Observer* with the majority of Uva men, never swerved in their support of Sir Arthur Gordon who was now deeply committed to Railway Extension without break of gauge until Uva was entered. Here is a letter written after a great meeting in Kandy where the Badulla representatives were induced to give support to a general resolution in favour of Extension:—

"The Hill Club, Newera Eliya, 25th February, 1887. Dear Mr. Ferguson,—I have just read your railway articles with much interest and satisfaction. The resolution in Kandy was carried not merely *nem. con.*; but *unanimously*. Messrs. Rettie, Hoseason, and other Badulla representatives agreeing to the wording as finally adopted without any hesitation.

"I think the opinions I heard expressed after our P. A. meeting are correct ones, that the proceedings generally were characterised by moderation and common sense. *Entre nous*—H.E. is with us on this medical question.—Yours faithfully,
R. BEAUCHAMP DOWNALL.

"H.E. was quite satisfied with the railway resolution, at least he told me so.—R. B. D."

At length in March 1888—sixteen years after the commencement of the agitation and nine years after sanction to Nanuoya—came the telegram from Sir H. Holland (afterwards Lord Knutsford) to Sir Arthur Gordon sanctioning Extension to Haputale, the Despatch being dated Feb. 20th. Here was Mr. Downall's genial deliverance on the achievement of a result for which he had worked and fought and waited so long:—

Dambateone, Haputale, 19th March, 1888.

"Dear Mr. Ferguson,—Congratulations all round—please accept mine yourself and convey them to your senior. It is indeed satisfactory to know that the great question is now undoubtedly settled, and that the Despatch is quite unconditional and unqualified, for it sanctions Extension to Haputale on the present gauge; of course that was a foregone conclusion.—Yours faithfully,
"R. BEAUCHAMP DOWNALL."

It was characteristic of the writer that in the same letter he should make inquiry about the Collectorate of Canara whether he intended proceeding on a shooting expedition though far from well. Indeed, for some years Mr. Downall had been suffering from the after-effects of a dysenteric attack (we believe) that would have made anyone less high-spirited and plucky, extremely careful of himself. Nothing could keep him from his usual active pursuits. After he took up his residence in Haputale, he became the very life and centre of the district, showing a bright example of attention to planting duties, but at the same time ever ready of a Saturday afternoon for the local cricket practice or match, or ready at intervals to captain the district team in competition with other districts or town teams. But this was not all; he would also have his occasional sporting tour either to the lowcountry or to India, in either case running risks which were not for him in those latter years in view of internal trouble. We recall well a pressing invitation he gave us to visit him at Dambatenne in Feb. 1886; he was expecting Governor Gordon on his first visit to Haputale via Ratnapura and Balangoda, and on his way to inaugurate the new Province of Uva. With great regret we had to forego the Dambatenne visit, only having time to get direct to Badulla for the vice-regal tamasha. Riding down from Nuwara Eliya, half-way to Wilson's Bungalow, we met Mr. Downall riding up. He had entertained the Governor the night before, the whole district gathering to present an address, and after seeing His Excellency and suite start for Badulla, he (Mr. Downall) had left the estate and was on his way to Southern India. Questioned as to his object, at a time when we knew he was in far from robust health, he said he had never shot a bison, and must do so before he went home, so he was on his way to its native haunts. It was again characteristic of Mr. Downall that

* These are given as bearing on Railway Extension and coming from Uva with which Mr. Downall was so closely identified: on February 17th, 1879, a formal Resolution to the same effect had been carried in the Parent Association, Kandy.

he maintained his faith in coffee up to the very end. We have a letter dated February, 1887, in which he got quite angry with the *Observer* for publishing a correspondent's sneer at coffee in Uva as being as much doomed there as anywhere else in Ceylon; the writer went on to say that tea would more than fill the place of coffee and fully justify the railway; but still Mr. Downall was not satisfied. He wrote:—"Many estates have just given the best autumn crop that has been gathered since 1878, and "the coffee looks in first-rate vigour after it." Alas! for the ever-sanguine as well as energetic proprietor of Dambetenne in the "eighties": well would it have been for him to have lost faith in the old staple, or rather to have gone in more extensively for the new king, a little earlier. But still he did a good deal in "tea"—he was never the obstinate or prejudiced planter who would learn nothing from his neighbour, and had only life been spared, there is no reason to suppose that he would not have reaped the benefit of the new staple to the full extent of clearing off all liabilities and finding himself sole owner of plantations which are about the most valuable in tea that Haputale can show in the present day.

And now in conclusion as to what kind of man, in person and character, was Mr. R. B. Downall. It has been well said that when a friend, loved and admired, passes away from us, there is a natural desire for something which may serve to give distinction and permanence to the impression which he made upon us in his lifetime. We trust that end has been in some degree met by what has been written above, and more especially by the contributions of two of Mr. Downall's nearest and dearest friends. It may be well though that we should recall in a few words the outward appearance: below the middle height, slender and active,—indeed in his early days "hard as nails" would best describe R. B. Downall in view of his constant exercise, riding and walking over plantations, cricket and hunting. He had a strikingly frank countenance, marked with lines indicating decision and responsibility and crowned by a notable forehead. It was natural that one who had made his way to the top of the planting "tree" at so early an age entirely through his own character and exertions, should be distinguished by an air of responsibility and command; but no one could be five minutes in his presence without discovering the really genial and kindly social character of the man. His smile brightened all about him and his laugh was contagious. But it is to the solid character and bright example of industry, energy and pluck that we would point at this time. No one

could ever dream of associating a mean or dishonourable act even in the slightest degree with R. B. Downall; while many acts of benevolence and of kindness to the bereaved and poverty-stricken will never be known till the day shall declare. No estate inspector or proprietor was more considerate towards those under him, or more desirous that Superintendents, conductors and labourers in his employment should all be contented and prosperous. Such then was this Ceylon Planter-pioneer of the "sixties,"—the chosen representative of his community in the "seventies" and "eighties,"—and we may add the most truly esteemed and widely loved of all the second generation of PLANTERS IN CEYLON:—

"Peace to the memory of a man of worth."

MEXICAN TOBACCO.

Ever since the dawning of what is called the "American Epoch" of Mexico, there has been a steady and continuous development in the exports of that country. The American Consul at the City of Mexico says, "That striking as are the facts with regard to the increase of the cultivation of coffee and the growth in the United States of a great appreciation of the Mexican berry and its sterling qualities, these can be paralleled in many points by the development of Mexican tobacco." Although France has not profited commercially by this increase, it is only simple justice to say that it is due very largely of Frenchmen and to the exiles from Cuba whom they employed. A French writer, Louis Lejeune, was the first to point out that the tobacco grown in the upper valley of the Papaloapam River produced leaves as fine, as silky, and even more aromatic and perfumed than those of the "Vuelta Abajo" in Cuba. He showed that the Plantations in the Pinar del Rio district of Cuba were exhausted, and that not even the most lavish use of fertilizers could enable them to produce leaves of the real Habana quality. He compared the western end of the island of Cuba to a dying fire, where one could find here and there points of living flame, but everywhere else ashes and blackened embers. M. Lejeune in his pamphlet made an elaborate comparison of the relative cost of starting a tobacco plantation in Cuba and in Mexico, and showed that, supposing silver to be at par, which it was when he wrote, the expenses in the latter were only one half of the former, without taking into consideration the price of land or the cost of transportation. He adjured his countrymen, who were enterprising, not to wander off to Cochin China, but to establish themselves in Mexico on tobacco plantations. Some did so, and at the last French exhibition those who had followed his advice received gold medals for the excellence of their production. For some reason or other the French Regie did not, until the fiscal year 1894-95, except Mexican tobacco, and, therefore, France has lost the benefit to which it was fairly entitled through the energy and skill of Frenchmen who created the initiative which has resulted in ranking the Mexican leaf with the Habana. Prior to 1889 the export of Mexican tobacco rarely amounted in value to 900,000 Mexican dollars in any one year (say £90,000), but in 1895-96 the value amounted to 1,700,000 dollars (£170,050). At first foreign countries imported Mexican cigars, but they did not give complete satisfaction, because boxes marked "Colorado," "Colorado Claro," and even the "Claro," when opened were found to contain "Maduros" and even "Oscuros." The supposition was that this was due to negligence in making the boxes, or even to fraud, because the light-coloured

cigars are preferred as being milder. This was a great injustice to the Mexican importers, who are most careful on these points. The enigma was solved by the discovery that Mexican tobacco ripened with remarkable rapidity, and that "Claros" became "Oscuros" during the short transit from Vera Cruz or Tampico to New York. The remedy was clear. It was to import the leaf and manufacture the cigars under climatic conditions that would prolong the ripening process. This led to a very brisk demand for leaf tobacco, and the Indians in the tobacco belt of Mexico were so foolish as to add corn shucks, grass dirt, and even stones to add weight to their bales; especially was this so in the case of that bought and shipped to Germany. The consequence was that there was a reaction, and the buyers for foreign houses would not look at any tobacco that did not bear the inspection brand of some well-known French, German, or Mexican house. Then the Indian growers were in despair and offered their tobacco for the price of seedling tobacco. American buyers jumped at the price and thus the exportation to the United States for 1893-94 reached the figure of 382,767 pounds, as against 70,107 pounds for 1891-92, but this was not maintained. Practically no wrapper tobacco is grown in Mexico. The leaf is all "filler." This is a virtue to those who like a strong cigar, easily smoked, but it is a defect for the general consumer who likes a milder article. When cigars were mostly made in Habana the wrapper was "Yara," and not the "Vuelta Abajo," for that very reason. A comparison of the prices paid for Mexican leaf tobacco by the various importing countries may be of interest. Germany, the chief importer, pays 37 cents per pound; the United States, 33 cents; England, 39 cents; Belgium only 29 cents, and France, only 25 cents per pound. The finest Mexican cigars go to Habana at one dollar 67 cents per pound; England gives 94 cents for Mexican cigars; France one dollar 10 cents, and the United States, 88 cents. In Mexico the soil is so deep that it is not necessary to plant a crop of corn after the crop of tobacco, and instead, the growers raise a second or seedling crop. After the plant has been cut, a stalk or chute springs abundantly, and from this stalk or chute spring small and very mild leaves, about the size of a man's hand. These are utilised by the manufacturers of cigarettes. To the factories in the country this tobacco is sold at from 2 to 5 cents a pound. The cigarette tobacco is excellent and its reputation is very good. Colombia and Peru buy it in constantly increasing quantities at from 6 to 9 cents per pound, and Guatemala buys at 6 cents. All of the Central Americans and some of the South Americans buy the Mexican cigars and pay an average of 1 dollar 5 cents per pound. In a word, says Consul Crittenden, Mexico is not only one of the coming coffee countries, but is also a coming tobacco country. Mexico seems to be destined to wear the mantle of Habana in tobacco production, and once secured, it is safe to predict that it will never pass away, for the soil of the tobacco region is so deep as to be practically inexhaustible, being from 8 to 20 feet in depth, and in some places even 30 feet. Moreover its extent is probably one hundred times that of the Cuban tobacco region, when we take into consideration the fact that acre for acre the percentage of cultivated land at the present moment capable of producing tobacco of the very highest grade is greater in Mexico than it ever was in Cuba in its best days; we can from this easily see what will be the amount produced in the future. Mexico's resources in this direction are practically so great as to make it certain that it will become rich from its tobacco alone. No doubt the results will be finally to cheapen the "Habana" cigars, and put them within the reach of all. The tobacco lands of Mexico form an immense inverted capital T, the cross stretching from Tuxtepec, (Oaxaca) and the upper valley of the Papaloapan through the southern portion of Oaxaca into the Tehuantepec highlands, and thence into the state of Chiapas; the upright of

the T stretches from the valleys of the Colorado and the Trinidad rivers (which form the San Juan river) eastward to the San Andres Tuxtla Canton. The cream of the tobacco lands will undoubtedly be found in the valleys of the Colorado and Trinidad rivers, but chiefly the latter. The soil in these valleys is from 10 to 15 feet deep, and of the very richest quality, and is equally adapted for coffee or tobacco. It may be taken as axiomatic as regards Mexico that the land that is good for one is equally good for the other. To the eastward of the main valley of the Trinidad river, in the transverse valleys, the soil is even deeper than 10 to 15 feet, and here one finds mahogany trees of the most astonishing size and of the finest quality. This region is called Las Monterias de Caoba, and is very extensive. Transportation is one of the most important questions which the planter in Mexico has to consider. In the Trinidad region he is close to the National Tehuantepec Railway, and he can also raft down to Vera Crnz. which town is reached by the small river steamers that ascend the river from Talacotalpam. He has two ports, Coatzacoalcos and Alvarado. Whenever the Railway from Corodoba reaches Tuxtepec, it will undoubtedly be extended to Juili on the Theuntepec line, and must traverse the Trinidad region, so that on the score of transportation one is reasonably assured being amply provided for in the present, with the probability of still more accommodation in the future.

NUTMEGS.*

The author of this book begins by saying how interesting he found the study of the Nutmeg-tree, both true and false, during a period of eight years spent in the Eastern parts of the Malay Archipelago and in New Guinea. There these trees enjoy a climate exactly suited to them, and there, in consequence, is situated the centre of their distribution. There also they take the same relation to botany that Birds of Paradise do to zoology.

The claim of the Nutmeg for consideration as an article of commerce is connected with a series of romantic stories of its discovery in times long past, of the fierce war that raged among European countries for their commercial rights, of the combat for monopoly that ended in the extermination of the natives, and the break-up of the greatest merchant-company that has ever existed. All this eventful history is interwoven with the stillness of every grove of Nut-meg trees, and with the grand scenery of every inland lake.

With such words as these, the author commences a work which is, in its way, unique. He proceeds to treat of the history of the Nutmeg previous to the discovery of the Banda Isles, of the use that has been made of it in poetry, and of the philological history of the various names for Nutmeg and Mace.

The second part of the book is devoted to the cultivation of these spices, and includes a large amount of cultural detail and history. We are told of the strenuous endeavours made by the Dutch East India Company to preserve the monopoly, and how finally they were forced to relinquish it; and the author further reminds us of the exertions that were made with more or less success to induce the Nutmeg-tree to flourish and become naturalised in other localities. Dr. Warburg notes that at Syon House, Middlesex, very large fruits have been brought to perfection. It would be interesting to learn whether this tree is still flourishing. [No, it was removed some years since. Ed.] In an appendix to this section of the book is a tabular epitome of the cul-

* "*Die Muskatnuss*:" the Nutmeg, its history, botany, cultivation, trade and value, also its imitations and surrogate. With a treatise on the cultural history of the Banda Isles. By Dr. O. Warburg. With three heliogravures, four lithographic plates, one map, and twelve illustrations in the text. (Leipzig, Engelmann, 1897, 8vo, xii., and 628 pages. Price 20 marks.)

tivation of Nutmegs and Mace from the years 1634 to 1894—that is, during a period of 260 years.

The third and botanical division of the book deals with the Nutmeg-tree itself, and numerous other spices that merit attention from a commercial point of view.

The fourth division is concerned with the cultivation, the fifth with the trade details. Not only the species recognised in commerce, but the false Nutmegs, and the substitutes for the genuine spice are fully considered. In an appendix to this section of the book are given detailed price-lists of Nutmegs and Mace.

The sixth section deals with the collateral products of the Nutmeg-tree, their commerce, and history. Among them are oil of Nutmeg, oil of Mace, candied Nutmeg fruits, candied Mace, and Nutmeg fruits in vinegar or salt.

In the seventh division the medicinal and aromatic products of the Nutmeg-tree are considered, and the poisonous qualities of the Nutmeg receive due notice.

In the eighth section the author considers the future prospects of Nutmeg cultivation.

Finally, there is a complete literary catalogue of some eighteen pages, which speaks well for the thorough acquaintance of the author with his subject. A very complete index greatly adds to the value of the book.

We congratulate Dr. Warburg on the completion of this work, which will serve as a model for all future books of the kind, no such complete monograph having before appeared. Everybody, be he botanist or gardener, chemist or philologist, historian, political economist, or merchant, will here find a wealth of information, whilst the general reader will find it a most interesting and instructive work to add to his library shelves.—*Gardener's Chronicle*, July 3.

GATHERING RUBBER IN THE FRENCH CONGO.

By Mrs. Martha Nehne.*

1.—FROM THE NEW YORK SUN.

In the months of March and April, during the rainy season, one sees busy life in the native towns of the French Congo. The men are preparing to go to the bush to cut rubber. Every woman and child seems to have something to do, and even the men do not lounge about as usual, but are sharpening their knives and *machetes* and putting their guns into proper trim. The women are digging *cassava* and some of them are washing it and preparing *chiguanga*, or native bread. Others are cleaning the *cassava* with knives and tying it into *mattets* made from palm leaves. This kind of *cassava* is roasted over the fire and eaten warm, while the bread is eaten cold and is mostly used on the road. The men carry their guns so that they may be prepared to kill the game which abounds in the forest.

When all is ready a drunken carousal and dance are given the night before the start by way of saying farewell to the villagers left at home. Sometimes a good place with plenty of rubber plants is found after a march of two or three days, but oftener the journey takes a week or more. In this case the men keep carriers on the road with food for them because there is nothing to be had in these parts with the exception of game.

The rubber in central Africa is not a tree, but a vine, often three or four inches in diameter. This vine generally climbs up the tallest trees, and the natives often use one of the vines to ascend the tree. After the branches are reached, which in most cases are at least fifty feet from the ground, the men proceed to cut the vines away at the top,

leaving only one for their descent, and this one, if possible, not a rubber vine. It seems strange that the natives cut away the rubber plants and so destroy them instead of tapping them, but they are too lazy to learn any other way.

After the vines have fallen they are cut into lengths of three or four feet, and the juice is collected into iron pots. This is a tedious job. The piece of the vine is held over the pot, first by one end, then by the other until the juice ceases running. Then the piece is cut again to get at any juice which may have been left in the middle. After a pot is nearly full a rest is taken, and this juice is boiled for nearly two hours, and, during the boiling process, is mixed with the juice of other vines and some lime juice, so that the mixture is more sticky and easier formed into balls.

As soon as it cools down sufficiently to be handled the hardening rubber is shaped by winding it at first around a stick. After a bit the stick is pulled out and the ball is re-wound to finish it off. In some places these balls weigh three pounds or more each; in others, five of them make a pound. The purity of the rubber depends much upon how much other juice has been added. The best and purest is that obtained from the juice without boiling. This is only found in the shape of bracelets, because the natives wind the juice as it runs out around their wrist and let it dry there. When perfectly dry it slips off easier. This would be transparent rubber if the skin and fingers of the natives were not so very dirty.

The natives often used to put foreign substances, such as small stones, palm-nuts, and little balls of grass into the rubber ball to make it heavy. They were soon found out, and every ball is now cut through the center to reveal its mixture. Often the rubber is buried for some days because it draws the moisture from the ground, which adds to the weight. Cheating is resorted to because the pay is so poor. It takes a party of eight or ten men and boys six to eight weeks to gather from eighty to one hundred pounds of rubber. The value of this, if all is first-class, is from 200 to 250 yards of cotton cloth or forty gallons of rum or three or four flintlock guns. Surely this is poor pay for this kind of work.

Still, the natives rejoice greatly if the men from one town return with 100 pounds. It seems like a fortune to them, because they need so little that civilized people crave and pay for. When this little fortune is spent and the weather permits, another trip is undertaken to the rubber region.—*India Rubber World*.

PACKING SEEDS AND TUBERS FOR LONG JOURNEYS.—The *Chenil*, as quoted in the *Revue Scientifique*, mentions a method of forwarding and packing seeds and tubers which seems ingenious and practical, especially when the journey will be long, and warmth and dryness are likely to have injurious effects. The method employed by a Lot florist consists in moistening a little plaster, and imbedding the seeds, tubers, or rhizomes which are to be transported in this. This plan has succeeded well for packing rhizomes sent from Japan, roots of aquatic plants, the lengthened transit of which is always a difficulty. Enveloped in plaster, the plants, or pieces of plants are in no danger; they cannot become parched, and are kept in a satisfactory condition of partial moisture. It would seem that this plan would also succeed under other conditions—in Australia it is employed for the transport of fresh butter. The butter is made up into blocks with parallel and rectangular surfaces, to which are pressed glass slabs of the same sizes as the sides and ends of the blocks of butter. The edges are covered with gummed paper for greater security, and the whole is then covered with plaster to a thickness of 6 millimetres. Plaster being a poor conductor of heat, secures the butter against the variations of the temperature, and enables it to be kept longer than is possible under other methods of packing.—*Gardener's Chronicle*.

* The writer of the information printed here is an American lady who for the past nine years has been a missionary in the Mayumba district of the French Congo.—THE EDITOR.

AGRICULTURAL DEVELOPMENT IN JAMAICA—AND IN CEYLON.

The subject of "agricultural development is one that may be regarded as a continuous permanent topic of discussion in Ceylon. We can never exhaust it, for there is always some "new product" or some fresh development of existing industry which demands attention. Now our text is found in the interesting and instructive extracts we have been tempted to make below from a lecture recently delivered in Jamaica by Dr. Morris, C.M.G., of Kew, before the Governor and a large body of the residents. This lecture was followed by an animated discussion in which the Governor bore his full share; and if it be true that Sir Henry Blake is ere long to succeed Sir Charles Mitchell at the Straits, with the reversion some years hence, possibly, of the Governorship of Ceylon, a more than ordinary interest will attach to his views and to his personal experience of agricultural development. Dr. Morris travelled over a wide range of subjects: he is particularly sanguine over the prospect opening before Jamaica of developing a great fruit-growing industry and export to meet the yearly growing demand from the United States. We need not follow him in all he says under the head of "bananas, grapes, oranges, grape-fruit, pine-apples, tree tomatoes," or even "potatoes." It may be hard to say what Ceylon could do as a rival with existing fruit-exporting countries were her resources properly tried and with the aid of refrigerating rooms in ocean mail-steamers. But, apparently, that time has not come yet; and we are more concerned, practically, with what he tells us about ginger, tobacco, fibres and agricultural teaching. What Dr. Morris says under the last heading is of special interest. He believes in agricultural teaching: he would begin even in the elementary schools, and the sooner the two "Readers," so much praised, are introduced into Ceylon, the better for the rising native generation; while, undoubtedly, to follow up such elementary learning, there ought to be a special Agricultural School or College in a Colony like Ceylon. Strangely enough, Dr. Morris did not give much encouragement in reference to fibres—Ramie, Rhea, or China Grass (all three exchangeable terms) was the only one suited to Jamaica, and even for it he spoke very cautiously, although he was met eventually by good reasons from the Governor why the people of Jamaica should do a good deal in Ramie and Rhea growing and preparation. So, in respect of "rubber," Dr. Morris is afraid to encourage any ventures, because of the continued large developments of original sources of wild rubber in so many parts of Africa. But we scarcely think Dr. Morris makes sufficient allowance for the constantly widening and increasing demand for rubber;—the thousand-and-one uses it is put to, which were not dreamt of a few years ago, and the thousand-and-one additional uses which the next dozen years or so may bring to light. Then, if we bear in mind that to plant and bring a rubber plantation into bearing, requires ten to a dozen years, we suspect there is every reason to anticipate a widened demand and a lessened supply from Africa, as from South America, the Eastern Archipelago, Assam, &c., before A.D. 1907-9 is upon us. Agriculture and planting everywhere have their attendant risks, in all their branches; but in Ceylon—following the Heneratgoda ex-

perience as tabulated by Mr. Willis—we consider Para Rubber Culture as safe an industry as and which can be recommended to capitalists any planters who are not in a hurry for immediate returns.

AGRICULTURAL DEVELOPEMENT IN JAMAICA.

EXTRACTS FROM LECTURE BY DR. MORRIS,
C.M.G.: GOVERNOR SIR HENRY BLAKE
IN THE CHAIR.

BANANAS.

The cultivation and export of bananas are industries of very recent growth. In 1886-1887 the value of the bananas exported from the Colony was £145,959. Last year the value had increased to £315,821.

I am aware that the prospects of the banana trade with the United States are not so favourable as they once were. It is therefore of great importance that new markets should be found and the recent trials of shipments of fruit to England deserve to be fully followed up.

GRAPES.

At last in Jamaica, thanks to the initiative of His Excellency the President, grape cultivation is now being generally taken up in the neighbourhood of Kingston. On the table tonight are fine samples of Black Hamburg Grapes grown at the Hope Plantations. It may be possible before long to supply all local wants in this delicious fruit and eventually export some of it in the early winter months to New York where fresh grapes would be greatly appreciated and command high prices.

ORANGES.

The capabilities of Jamaica to ship large quantities of delicious oranges is a most striking proof of the vast resources of the island. Hardly any orange trees have as yet been systematically cultivated here. Yet there are several millions existing over the island in a semi-naturalised condition. From these trees the export of fruit in 1886-87 was of the value of £58,288. Last year owing to the falling off of supplies from Florida there was a keen demand for Jamaica oranges in the United States. Jamaica was fully able to meet this sudden demand and it shipped oranges of the large value of £169,293. I am glad to find that steps are now being taken to cultivate oranges in a thoroughly systematic manner and that budding and grafting is being regularly pursued.

GRAPE FRUIT.

Amongst citrous fruits there is no fruit which appears to be in greater demand and obtains such high prices as the grapefruit. This is a variety of the shaddock or pumelov. It is so called because it grows in clusters as in a bunch of grape. On account of its tonic properties it has lately come into great request in the American market. The most esteemed sort is of good size, with a pale yellow, polished rind. Grape fruit should be allowed to get thoroughly full on the tree. Immature fruits are of an inferior flavour. The season appears to be from December to April. The tree when budded is a vigorous grower and very prolific. It is recommended to bud on either the sour orange or rough lemon stock. If the soil is deep use the sour orange stock. If shallow and rocky use the rough lemon stock. Provided the fruit is full juiced and of a delicate flavour the larger sizes are more in favour than the smaller ones.

PINE APPLES.

There appears to be an increasing demand for pine-apples just now in New York owing to the falling away of exports from Cuba. The best season is during the months of March to May. There is no fruit that gives a better return for the extra care bestowed upon it especially in grading and packing.

TREE TOMATOES OR PLUMS.

I find that these are not appreciated in America. Their use in Jamaica has been always regarded as beneficial as a liver tonic. There is no doubt of their wholesomeness. They evidently require to be tried

on new lines and used for such purely dietetic purposes as those which have given such special value to the grape fruit. The tree tomato is sometimes to be found in the Covent Garden market where it is received from Madeira. It is generally known in England as the granadilla; but it is not a pressive fruit. It is more closely allied to the tomato. Any man who buys a tree tomato and expects to find a hard stone in it is disappointed. I think it is a pity to call it a plum—a gooseberry is a better name for it—for it is a berry and in no case or condition is it a plum. But whether a plum or a berry I am afraid its qualities are not appreciated in America. I am afraid Jamaicans do not approach the American in the right way. The right way to approach him is on the dietetic side. In the island where the largest stock of it exists at least where it originated he might say (although it came originally from Peru), there is no place where it grows so freely as in Jamaica and it is a great pity something more is not done with the fruit.

POTATOES.

In my lecture, already referred to, I recommend that an attempt should be made to grow new potatoes for the New York market. Such potatoes are a luxury in northern countries during the winter months. Hence they obtain comparatively good prices. So far, experiments have been on a small scale. I find, however, that an attempt made last year, although seriously affected by the drought was not of an unpromising character. It might be suggested to make three plantings in the season, say about November 1st, November 15th and December 1st. The crop should be ready for shipment from January 15th to March 15th, thus covering the best shipping season. It is essential that the seed potatoes should be specially selected for planting purposes. In the Bahamas for early planting rather small uncut seed potatoes are used. Later on larger seed potatoes are cut to two eyes to a piece. These are said to give a larger and better return. The tubers should be gathered when fully developed and packed in stout wooden cases. No wrapping is necessary. With potatoes as everything else they should be presented in as fresh and attractive a way as possible.

GINGER.

Of the small industries of Jamaica there is hardly one more worthy of attention just now than ginger. During the whole time I was in Jamaica I regarded ginger as my personal enemy. I understood that the culture of it is detrimental to lands in the interior. But I have had most gratifying news from His Excellency the President of that Society that by means of suitable manures the land had been saved. There has been a considerable rise in prices of late years. For instance during the last 10 years what is commercially known as common Jamaica ginger has risen from 51s to 74s. per cwt. whilst good qualities have risen from 62s to 93s 6d per cwt. Hitherto ginger has been regarded as a most exhausting crop, requiring fresh forest land to be cleared every year.

LOWLANDS AND HIGHLANDS.

I think that the sooner we can turn the attention of the provision cultivator from the high lands to the interior—the low lands—the sooner the better for the interests of the island. On Saturday afternoon I went up in the direction of Blue Mountain Peak and fortunately it was a beautiful clear day and one on which a fine survey of the island was obtainable. From what I saw I was perfectly satisfied that forest land was still being cleared at high levels for provision grounds and that this land is practically being ruined from year to year. The only way to prevent this is to give the peasant proprietor the means of the knowledge to turn these abundant lands in the island to some good account—to divert his energy from destroying the various lands and devoting them to the cultivation of the lands in the low lands. I may tell you this—that the low lands in Jamaica are far richer than the best forest lands in other countries. I am afraid we have been spoiled by having so many advantages in Jamaica,

As I said before I came to this meeting "all the logwood in the island came to you by the hand of nature; all the pimento crops have been a present from nature's lan." All the orange crops which last year reached the total value of £490,000 all these oranges were sown for you by the birds. They came to your pastures in spite of you, and you reaped the handsome return. It is impossible that an island like this is going back or that it can be depressed, if the people of the island will only muster their strength and energy, and put their ability forward to raising crops suitable to the island and suitable for the markets that are around us.

TOBACCO.

This is a very interesting Jamaica industry. Its development has not been free from vicissitudes; but where the cultivation is in the hands of experienced Cubans the quality of the produce is of high order. At one time there was a considerable trade in tobacco and cigars with the United Kingdom. That fell off for some time, but latterly it has again improved. It would be a very fortunate circumstance for the island if the large number of tobacco cultivators now driven out of Cuba were induced to settle in Jamaica. There are extensive tracts of land suited to the cultivation and the industry might in a few years assume large proportions. It is a singular fact that only the Spanish speaking people have become successful tobacco growers in the West India Islands. Europeans who have attempted to start tobacco growing have almost invariably failed. Jamaica cigars are now in great demand in neighbouring countries and they are pronounced to be as good as the Havana cigars.

FIBRES.

Now that the cultivation of Sisal hemp has been so largely taken up in the Bahamas and Turks Island it is probable that they will be able to supply fibre necessary to supplement that produced in Yucatan. Jamaica has so many other and more promising industries that I can hardly recommend it now to take up that of growing white rope fibres. The only fibre industry that is at all suitable to the present circumstances of Jamaica is that known as China Grass or Ramie.

The plants yielding these fibres are allied to the common nettle but without stinging hair. Numerous straight shoots grow up to a height of 4 to 6 ft. The inner bark of these shoots contains a fibre which is pre-eminent for strength, fineness and lustre. It is necessary first of all to strip the bark from the stems and produce dry strips which are known in commerce as "ribbons." In the second place it is necessary to treat these ribbons by means of chemicals and extract the fibre in the form of white soft threads known as "filasse." The chemical part of the preparation has apparently been successfully worked out. The chief difficulty now is with stripping the bark from the green stems. Numerous machines have been put forward for this purpose but, as far as I am aware, and I have seen and carefully tested nearly all those brought out during the last 20 years, not one can be said to have been completely successful. The fibre that is now used in commerce has been cleaned by hand in China. It is regularly woven into beautiful fabrics resembling the finest damask. If once the mechanical difficulty of separating the ribbons from the stem was solved, a China grass or ramie industry might be very successfully started in certain parts of Jamaica especially those with a rich soil and an abundant rainfall. It would be useless to attempt to grow these plants elsewhere except under irrigation and I am doubtful whether they would do so well under the latter system. I am sorry I am unable to give a more favourable account about ramie. Two machines have come out in the West Indies this winter—one has gone to Trinidad and the other to Jamaica. I don't know what reasons there are for the non-success of these machines, but so far I have not been able to hear a satisfactory account of either of them. I saw the one at work in Trinidad and the result was not satisfactory. I don't know whether the machines

in Jamaica will prove more promising than that but all that I can tell you is that at the present time I think I shall be doing you a favour by advising you not to embark in a ramie or China grass industry until you are satisfied that this mechanical difficulty in regard to stripping the bark from the stem has been overcome (hear, hear.) It is quite possible that this difficulty will be overcome because I was very pleased last winter in the Bahamas to see a thoroughly perfect machine work for more than two hours, cleaning and extracting the fibre from the sisal leaves. This machine was very simply constructed. The leaves were fed into the machine by a boy and the fibre was taken out at the other end by a woman—these were the only persons connected with the machine at all, except of course, the man driving the engine. The leaves were all fed in sideways—leaves that were four, five, six or seven feet long were put on the feeding table and a small boy pushed them into the machine at the rate of 40 to 60 leaves a minute. A large wheel was working across the machine that cleansed this end of the leaf. There was a large clamp that held the part that had been cleaned while the remaining portion was presented to a wheel working in that direction: the fibre was delivered at the end of the machine perfectly clean. I sat by that machine for two hours and it worked like clock work. That was a Todd machine, but there is another machine which turned out at the rate of half a ton per day. The difficulty has been entirely overcome as regards extracting fibre from sisal hemp.

AGRICULTURAL TEACHING.

Most of the industries which I have reviewed this evening require for their successful issue a certain amount of skilled knowledge amongst the cultivators. A man that can simply hoe canes or weed coffee is of little or no use in the cultivation of delicate fruits. Jamaica will never be able to successfully compete with other countries until it has educated its people in right methods of growing, pruning and manuring plants and in preparing the produce in an attractive manner for export purposes. The work of training agriculturists must be beyond theoretically at least in the elementary schools of the country. Already something is being done in this direction by the Board of Education and two 'Jamaica Readers' the use of which will be compulsory in all schools. These Readers consist of lessons on plant life and treatment of common objects of cultivation throughout the island. I had an opportunity of reading the proofs of these interesting little books and feel sure they will be of invaluable service in familiarising the children with the proper mode of cultivating crops suitable to the island and in preparing them later on to take up the systematic study of agriculture as a science. They will be read by adults as well as by the children. As long ago as 1887 Mr. Craig was instrumental in the Legislative Council in obtaining a valuable text book of tropical agriculture from the pen of my friend Dr. Nicholls of Dominica. This work has greatly assisted in the teaching of agriculture in colleges and schools not only in Jamaica but in other parts of the West Indies. Steady pursuit with such various agencies as these cannot fail eventually to raise the character of practical agriculture in the island and render the people more capable than at present in responding to the requirements of the markets of the world.

IRRIGATION.

This is a subject that has already been touched upon in the remarks I have already addressed to you. The great success which, at last, has attended the utilization of the Rio Cobre irrigation Canal and the enormous quantities of fruit which have been grown there will tend to bring up the practicability of extending irrigation to other parts of the country with a comparatively scanty rainfall. In the district of Vere it is believed that extensive areas could thus be maintained under cane cultivation and produce excellent results.

DEPENDENCE ON GOVERNMENT.

I think there's too much dependence in the West Indian Islands on Government (applause.) I think in a community like this in Jamaica we ought to try—I identify myself with you—we ought to try to do more ourselves and not depend on Government.

COCONUT OILS, ETC.

CEYLON.—The market is firmer in all positions. Early in the week the available stock at dock was closed out at 5c., about 50 tons being taken at this. Also 150 tons for June-August sail shipment from the Coast at 4-72½c., further business being declined under 4½c. For vessels on way 5c. is lowest, with offers of 4½c. being turned down for 100 tons. The market closes strong at 5 @ 5½c. for spot, as to size of package.—*Oil Paint and Drug Reporter.*

BORNEO TOBACCO.

We have seen some of the Lukutan tobacco off the New London Borneo Tobacco Company's estate on the west coast of Borneo, and find that it burns well, though with not quite so white an ash as the best Borneo. It is pleasant s flavour and the new experiment in that district is certainly a success.—*L. and C. Express.*

PRODUCE AND PLANTING.

THE TEA DUTY.—The reduction or abolition of the tea duty came up for discussion in the House of Commons on Monday, and led to an animated debate. The Chancellor of the Exchequer in a somewhat lame apology for leaving the duty as it is, twitted Mr. Kearley with having his own particular commercial interests in mind when complaining of the warehouse duty, but it seems to us that if the Chancellor of the Exchequer had simply stuck to his point that he would not afford to reduce or abolish the duty on tea, it would have been more to the purpose. It is quite unnecessary to infer that those who wish for a change in the present impost on a product which is now mainly supplied by British enterprise in India and Ceylon are seeking to serve their own interests because they happen to be connected with the tea trade. The desire for the abolition of the tea duty is not by any means advocated by all members of the trade, although we do not see why it should not be. The removal of the duty would be welcome to consumers of tea, and we cannot see the force of reasoning which admits that a popular article of food supply should be taxed to a certain extent, but no more nor no less. That there is a divergence of opinion amongst members of the tea trade on the duty question is undoubtedly a fact, and if those who are in favour of the present or any duty on tea were simply representative of the bonded warehouse interest there would be reason and method in the argument. But the contention that no change is necessary because the duty on tea is sufficiently low already and the article itself cheap enough, ignores the requirements of the poorer consumer altogether. It fails also to grasp the fact that, to say nothing of the advantage to the trade of freedom from the trouble now attending the bonding process, the abolition of the duty could not fail to give an impetus to the tea trade which, unless the laws of cause and effect and supply and demand are upset in this particular instance, would certainly prove beneficial to the Indian and Ceylon tea industries.

TRADE SUPPORTERS OF THE TEA DUTY.—It appears from what transpired at the quarterly meeting of the General Purposes Committee of the Federation of Grocers's Association last week that some prominent members of the trade are opposed to

reduction. One member went so far as to advocate the sending of a resolution by the committee urging Sir M. Hicks-Beach not to entertain the suggestion, as the duty was already sufficiently low. We have consistently advocated abolition or reduction of the duty in the interests of planters and the public. Apparently the *Grocer* is in favor of a similar policy, although it does not make itself clear on the subject. Commenting on the question of consumption it remarks: "Considering what the Imperial revenue takes out of tea, it is surprising that the public gets such good value in this article. Still we think it is wise to be slightly more extravagant in devotion to the teapot. One can't get much good out of it if little good is put into it; and no domestic idol better repays generous treatment. It forms a pleasant picture on the hearth as the shades of evening close in; even if replenished at the smallest pecuniary cost, it fills the cups that cheer and do not inebriate. Most of the gossip of the English race is stimulated by the teapot. What, indeed, would our dear ones of the feminine type be without it? A false spirit of economy should not, therefore be permitted to sully this noble cult, and grocers will do well to place the matter before their customers in its true light. The teapot is one of our cherished institutions. Let us put nothing into it likely to weaken its hold upon our heart or to induce an alternative taste for beer."

TEA BLENDING.—The prominence given to the tea blending question is making itself felt, not only by the emphasis given to its importance in the advertisements of dealers, but in the issue of pamphlets on the subject. In one of these the author points out that "the tea that satisfies London is not to the taste of the Midlands, which, again, may differ considerably from that in the north of England, Scotland, or Ireland. . . . It is the knowledge of this diversity of tastes which leads me to think that the individual grocer is throwing away a great advantage by pushing the sale of proprietary teas, or even of blended teas supplied to him in bulk. I venture to say that with comparatively little trouble he may blend teas better suited to the requirements of his connection than anything he can buy ready blended, securing at the same time an additional profit. . . . For an active business man doing a fair trade to be content to hand packets of tea over his counter, in the same way that he dispenses Bovril or Mellin's Food, is a suicidal policy which means not only less profit, but often smaller sales," inasmuch as a chemist or a confectioner is capable of distributing packet teas. The author strongly urges the necessity of testing the teas in the water of the district in which they will be used, and gives numerous useful hints as to the preparation of blends. Many wholesale firms test their teas in the water of the districts for which they are intended, and some retailers blend their own teas, and study the effect.

THE CEYLON "CREEPER."—The Ceylon "creeper" has achieved fame. He is the subject of innumerable newspaper articles. The *Globe* devoted more than a column to him in a recent issue, and, on the strength of this and other newspaper comments, the supply of "creepers" from these shores will no doubt increase merrily. The writer of the *Globe* article, who describes himself as a "Ceylon Tea Planter," lets the "creeper" down very gently. He describes his duties and gives him advice, but he does not emphatically say that there is no room for these young gentlemen. That is the point. The business is overdone, and for the present, unless under exceptional circumstances, there is no demand for young men on tea gardens, although possibly the offer of a considerable premium may have some effect in certain quarters. Doubtless young men with capital are welcome anywhere. They may always acquire experience in return for it, but those who are simply on the look out for something to do, and have no other qualification, will not find any special opening in Ceylon or India.

PLANTING IN LAGOS.—Sir Gilbert Parker read a paper at the Colonial Institute on Tuesday last on the Colony of Lagos. Referring to planting prospects he said: Lagos was destined to become an important coffee and cocoa growing centre. Two plantations had already been established, one at Soto in the Ilaro district, and another at Ajilite, both of which promised well. If attention were paid to fibre-producing plants, success would follow. The wild pine grew in great abundance in many parts of Yoruba, notably in the Idanre region, a chain of mountains which he discovered near Ondo in 1892, and visited in 1894. This fibre was used for making twine in some parts of West Africa, and was very strong. Other fibre-yielding plants, such as Sausiviera and Piassava, could also be had in large quantities. Cotton and a species of indigo were extensively grown in Yoruba, and although the indigo did not appear to be suitable for the English market, it was probably because the correct mode of preparation was not understood. The forests abounded in excellent timber, and an important industry must surely develop in that direction so soon as the railway offered facilities for bringing it to a port of shipment. The hinterland of Lagos possessed the advantage of having a large and industrious population, and now that the country was pacified its productive powers must enormously increase.—*H. & C. Mail*, May 14.

SCOTCH CEYLON TEA COMPANY.

ANNUAL MEETING.

The eighth annual ordinary meeting of the Scottish Ceylon Tea Company, Limited, was held on Thursday, May 13th at the offices, 16, Philpot-lane, E.C., Mr. H. L. Forbes (managing director) presiding, there being present Messrs. R. W. Forbes, G. G. Anderson, D. Andrews, E. W. Dodd, G. W. Paine, Capt. Grant, Messrs. J. C. Sanderson, J. M. Smith, G. Todd, Hugh Blacklaw, and J. F. Anderson (Messrs. Lyall, Anderson & Co.)

The Chairman said: Before proceeding with the business the directors wish to express their deep regret at the recent death of Mr. John Anderson. He was an original member of this company, and was at the head of the firm which at one time acted as our secretaries. He was a very near relation of some who are present, and a great friend of many of us, and took a very great interest in the company. I am sure you will all join with the board in passing a vote of deep sympathy with his relations in the loss which they have sustained, and in requesting the secretaries to convey it to those whom he has left behind.

The motion was unanimously agreed to.

Mr. James F. Anderson (Lyall, Anderson & Co.) read the notice convening the meeting.

The Chairman said: I think the report is one of the most pleasing I have had the pleasure to lay before you, most pleasing because, during the past year several matters have caused sundry difficulties in Ceylon. Labour was not too plentiful, and during the latter part of the year the exchange was rather against us, while the tea prices were not quite so favorable as they had previously been; but, taking it all round, I think you will agree that the results we present are remarkably satisfactory. You will note that we carried forward from last year £825 13s. 9d. Our net profits for the year have been £8976 15s. 6d., which leaves to be disposed of a sum of £9,829 9s. 3d. In September last we paid you an interim dividend of 5 per cent., free of income-tax, which absorbed £2,050. The seven per cent. preference dividend has been paid as usual, and it is now proposed to pay a dividend of 10 per cent., free of income-tax, which makes 15 per cent. for the year. We further propose to add £1,000 to the reserve fund, bringing it up to £7,000 and to write off for depreciation on buildings and machinery £797 2s., which leaves a balance to carry forward of £1,252 7s. 3d. The buildings and machinery on the estates are in very good order indeed but your directors

still think it advisable to write 10 per cent. off their value as taken on December 31 last. The total amount of the crop secured for the year was 720,200 lb., being 48,200 lb. over the estimate made this time last year and 52151 lb. more than the previous year's outturn. I think you must consider that remarkably satisfactory. I may mention, too, that the present manager (Mr. Kerr) and the gentleman who did his work last year both consider that they have not yet arrived at the total crop that may be expected. There are still 163 acres on one estate which are merely in partial bearing. As regards yield, we secured 422 lb. per acre, as against 433 lb. in 1895. The reason of that is very obvious, because the 163 acres in partial bearing have all been included in striking the average. The average price of the tea sold in London was 8'86d. per pound, and the average of all Ceylon teas was 8'25d., or, taking our average at 8½d. and the Ceylon average at 8½d., we are a halfpenny beyond the average. The 8½d. is slightly lower than that of last year, but there is only a fractional difference. The acreage of the estates remains practically the same. Thirteen acres were planted during the year, making 1,720 acres under cultivation. On the last occasion we had the pleasure of meeting you, Mr. Kerr (our Ceylon manager) was present. He left us, and resumed charge of the estates from February 1. During his absence Mr. G. M. Ballardie did his work, and did it as well as he did on a previous occasion, and I shall ask you to pass a vote of thanks to him in due course. I shall also have the pleasure of introducing to you my old friend Mr. Blacklaw—we have generally something on show here—an Oriental pearl from the East. (Laughter.) He has come home after a residence of twenty-one years in Ceylon without a break. I think he is a very good specimen of what the Ceylon men are. I myself retire from the board, but, being eligible, am open to re-election. The shareholders will also be invited to express their approval of the appointment of Mr. George Gray Anderson to a seat on this board. Mr. Laurie offers himself for re-election as auditor. That is the sum total of our report, which I think you will consider a very pleasing one. Our position is remarkably sound. The estimates for the present year have all come home, drawn up in the usual careful way by our Ceylon manager. The prospects are equally as good as those of last year. We have already arrived at the middle of May, so we know pretty well what to expect. The position as a whole has not deteriorated since last May. The only black spot is the labour question. It is a small cloud on the horizon, but I do not think it is likely to burst into much rain or do much harm. A good deal is being done to try and find a remedy, and I am glad to say that the Governor has taken up the matter, which no previous Governor has done, and I think, if we look to him and the planters' own energy and the Planters' Association, if matters do get worse we shall find a remedy for them. At the same time there is a bright lining to that cloud. If the tea bushes are not pulled about too much they last all the longer, and will yield dividends in the future. I always like to look at the bright side, even of a dark cloud. These are all the remarks I wish to make, and I have now the pleasure to propose the usual resolution: "That the reports and accounts be adopted"; but before putting it I should like to hear anything that any shareholder has to say, or any questions that it may be desired to put.

Mr. R. W. Forbes seconded the motion.

Captain Grant said the interest account was this year on the creditor side, but last year it was on the debtor side.

The Chairman said three months interest had to be paid on tea sales, and it was usually on the debtor side; but this year the Company had the advantage of having it on the other side.

Captain Grant said he had noticed that the receipts in Ceylon in respect of tea manufactured were going down every year. He supposed that was in consequence of the small gardens getting their own machinery.

The Chairman said the Company had been in the habit of buying large quantities of tea-leaf from estates which had no factory of their own; but many of those had now their own factories. He, himself, had not been in favour of purchasing the leaf to make for others. He did not think it was always a desirable speculation, because their employés had to give up their time to other people, and their own teas might not receive the same attention that they otherwise would.

Captain Grant asked whether it was more profitable to sell their own manufactured tea in Ceylon or in London.

The Chairman said that was a very difficult question to decide. Some teas are better sold in Ceylon; others are better brought to London. On the whole he thought the most favourable market was London.

Captain Grant said there was the question of plague. It might touch Ceylon on its return journey to Hongkong, and it might be necessary to burn the coolies' clothes, and furniture. Would they be amenable to reason and see that it was for their own benefit?

The Chairman.—We should do that first and then have a settlement afterwards. (Laughter.) Every possible precaution is being taken in Ceylon to keep the plague out of the island, and in all matters affecting it the Ceylon authorities are most particular.

The resolution for the adoption of the report and accounts was then agreed to, and "that a dividend at the rate of 10 per cent, free of income-tax, be paid on and after this date."

Mr. Donald Andrew moved and Mr. R. W. Forbes seconded the re-election of Mr. H. L. Forbes as a director, and it was unanimously agreed to.

On the motion of the Chairman, seconded by Mr. R. W. Forbes, the election of Mr. G. G. Anderson as a director was also carried, the former remarking that they had gained somehow the idea that that gentleman's presence on the board would increase the dividend. (Laughter.)

Mr. G. G. Anderson returned thanks.

The Auditor (Mr. J. B. Laurie) was reappointed, on the motion of Mr. G. W. Haine seconded by Captain Grant.

The Chairman proposed a vote of thanks to the Ceylon and London staffs. All the heads of estates in Ceylon were practically the same as when the Company started in 1889. Both staffs had the interests of the Company at heart, and did their work well and thoroughly.

Mr. G. W. Dodds seconded the motion, which was agreed to.

Mr. Hugh Blacklaw, in acknowledging the vote, said if those in Ceylon got on successfully with their work it was due to a great extent to the board of directors at home. They had a practical man at the head of affairs, who was of great assistance to the staff in Ceylon.

Mr. James F. Anderson returned thanks on behalf of the London staff.

On the motion of Mr. J. C. Sanderson, seconded by Mr. George Todd, a vote of thanks was passed to the Chairman and Directors, and the proceedings terminated.

OIL-SEED CULTURE IN UGANDA.—A report just published by the Foreign Office states that the cultivation of sunflower, ground-nut, castor-oil, and sesame plants has been thoroughly tried and proved successful in Uganda, British Eastern Africa. At Kampala an oil-press to be worked by animal power is in course of construction, and by this oil will be produced on a larger scale than has hitherto been possible. It is hoped that the oils may find a market as lubricants, but the local demand is also increasing rapidly.—*Chemist and Druggist*, April 17.

SALT AND AGRICULTURE IN CEYLON.

The manufacture and supply of salt to the public of Ceylon is a monopoly of the Government. Here, as in India, the difficulty of reaching the masses by any other form of direct taxation has been always the apology for a levy on an article so indispensable to human existence and to healthy, active life. To tax salt though has very frequently been realised as at best a painful necessity, and when one thinks of the possibilities of "free salt" both among the people and the soil, a longing to see the necessity removed, can with difficulty, be repressed. In the case of Ceylon, however, it has been pointed out that with the natural formation, or artificial manufacture of salt, confined to two points so remote from the chief centres of population, as are Puttalam and Hambantota, it is questionable whether, had we free salt and private enterprise, distribution could be more readily or economically effected than at present by Government which charges the monopoly price uniformly and is responsible for the local supplies. This may have been true in pre-railway days; but we entirely deny the force of the argument at the present time and still more when Puttalam is brought into direct railway communication with the capital and highlands. All this by way of introduction; but before we leave the subject, we would wish to add that any attempt to increase the salt-tax in Ceylon ought to be strictly resisted. Such an attempt was threatened if not made by Sir Arthur Havelock in 1892; and we think a protest we sent to Lord Ripon (then Secretary of State) from Port Said when on our way back to the island, helped to suppress such proposal.

Be that as it may, our topic of discussion today is one that is by no means unfamiliar to our older readers, although it has not been revived for some years now. The value of salt in several, if not all, branches of agriculture in Ceylon has long been recognised. To coconut and other palm and fruit-tree cultivation salt is of pre-eminent value. The coconut flourishes along the seashore in, apparently, very poor sandy soil chiefly owing to saline mixtures and deposits; and how greatly the trees could be assisted farther inland if salt were available for application, is realized by all planters. There are certain soils which could not fail to be benefited by salt applications, no matter what crop they carry; and in this way coffee planters of a bygone generation as well as rice cultivators, were very eager to have the Ceylon Government allow salt to be denaturalised, so that it could be had free of the monopoly tax to benefit agriculture. This the Government was by no means unwilling to allow, provided sufficient assurance could be obtained that the process of denaturalisation was so effectual as to prevent the salt being used for human food. A great many experiments extending over not a few years were made, but always with such unsatisfactory results that the Government had to refuse its sanction to the agricultural appropriation of salt. The question excited considerable attention throughout the administrations of Sir Henry Ward and Sir Charles MacCarthy and part of that of Sir Hercules Robinson and has been revived, at intervals since, but always without success. Nevertheless, the importance of the proposal to utilize salt in the chief industries of the island has, in no way, abated.

During his recent visit to Europe, the Hon. P. Coomaraswamy met an intelligent German who, manifesting an interest in Ceylon, after a time got on our salt monopoly. He showed that the Government monopoly was quite as strict in Germany; but that the problem of denaturalisation has been successfully solved, so that salt free of tax was permitted to be used for agricultural and manuring purposes. Mr. Coomaraswamy as a coconut estate proprietor was naturally interested, and in answer to a request for further information, a letter, of which the following is a translation, was received:—

Berlin W., Feb. 22nd, 1897.

The Hon. P. Coomaraswamy, London.

Dear Sir,—According to your wish I append an abstract of the German law *re* inland revenue on salt, dated the 12th December 1867:—§ 2. The inland revenue on salt is 6 marks for 50 kgr. (about 63. a hundred-weight), §20. Free of tax are the following:—

No. 2. The salt used for agricultural purposes, *i.e.*, for the feeding of cattle and for manuring.

No. 3. For pickling herrings and similar fish.

No. 4. The salt employed for all other industrial purposes with the exception of that for industries preparing nourishment and relish for men (vide No. 3 exception).

The salt for purposes (vide No. 2 and No. 4) must be denaturalized (article 5 of the agreement of 8th May, 1897.) This shall be accomplished by means of pulverised wormwood (enactment of the 25 March 1873.) I shall be glad to give you any more information, if wanted, and remain, dear sir, yours faithfully,

FR. LANGE.

We have asked Mr. Lange kindly to send us copy of the enactments referred to, so as to expedite the action which we have no doubt the Tamil representative will take in the Legislative Council to have the same privileges as exist in Germany extended to Ceylon. It is a matter in which both the Chamber of Commerce and the Planters' Association should take a special interest, and we trust the year 1897—notable in so many other ways—may see the long-desired permission given to Ceylon planters and agriculturists of all grades to use salt (certificated to be treated in the proper way) for application to their palm, fruit, rice or other cultivation.

CACAO DISEASE—THE GOVERNMENT— AND THE PLANTERS' ASSOCIATION.

The correspondence given elsewhere from the Planters' Association is, so far, satisfactory. It is reassuring to know that the Kew authorities have been consulted; but still more so to understand that they will not act hastily in sending out any specialist until after Mr. Willis, the Director of our Gardens, has reported after consultation with Mr. E. E. Green. We are especially pleased that the qualifications and local experience of the latter as Entomologist are being so fully recognized, and we trust the Government will not hesitate to adopt the recommendation of the Planters' Association Committee, and indeed to act even more liberally than is suggested. Mr. Green is the last man in the world to presume or aggrandize; like so many true scientists he takes too modest a view of his acquirements and, in his case, of his ability to help his brother planters. Now, none of us should expect Mr. Willis or Mr. Green to work wonders; but we feel confident that both these gentlemen will enter *con amore* on the task allotted to them and will give the best advice in their power to the Government. Of course, Mr. Willis is the responsible adviser;

but he has already shown in his Annual Report, how ready he is to profit by local experience and special training; and still more, how pleased he would be to see further scientific experts brought to bear on the economic problems affecting the leading agricultural industries of the island. As we have said, an Agricultural Science Board—comprising the Director, Conservator of Forests, an Agricultural Chemist, Entomologist, and perhaps, Cryptogamist or Fungologist—to experiment, investigate and suggest, (of palms as well as of tea, cacao, coffee, etc.) and of cultivators generally, could not fail to prove of decided benefit at this stage in the progress of the colony; and if Governor Ridgeway saw his way to establish such a Board, and to place it in active co-operation with agricultural, as well as official, representatives, a very notable advantage would be given to our greatest and most vital industries, and a decided impetus to material progress in a variety of directions.

CATERPILLAR PEST ON "ALBIZZIA" (TOON) TREES AND WITH A LIKING FOR TEA.

The following is the letter of a tea planter in a lowcountry district to a Colombo merchant:—

I am sending you, in a small box, some tea leaves with the "ca'ddis" and worm attached. As the pest now has got on to the tea after having nearly killed about 5 acres of Albizzias, I shall be much obliged if you will please show them to the *Observer* Entomological authority; and if he thinks it will be necessary to destroy them then the matter must be taken in hand at once. All the Albizzia trees with pest have to be cut down—as the worm drops on to the tea from them—and then coolies are put on to collect the worms. So far very little damage has been done to the tea bushes.

Our Entomological referee is good enough to report as follows:—

"Caterpillars of the genus *Psyche*. They reside in a case composed of fragments of leaves, bits of grass, &c, and in which they undergo their metamorphoses. Those cases suspended from the leaves by a thread, contain the chrysalides which might be brushed off by the hand if very numerous and close together. The escape of the moth is indicated by a portion of the empty chrysalis left protruding from one end of the case, within which the caterpillar has resided, and the chrysalis found protection. I have not heard of their doing much damage to tea. Colombo 7th June."

All this shows how much need there is for an Entomologist—not merely "honorary"—though that is better than none—but for one in constant work throughout the country. Possibly, the five acres of "toons" might have been saved if seen by an Entomologist at an early stage.

THE VINE IN THE MALAY PENINSULA.

Alluding to a recommendation in an Indian paper that planters in the Malay Peninsula should try the vine, the *Malay Mail* says:—

We are of the same opinion, and wonder why nobody has ever yet thought of going in for viticulture here. The chief question is, of course, one of soil. As for the climate, we should think little on that point is left to be desired. The sunlight is on the whole never too scorching, and the rains,

provided always that the vines were not planted along too steep a gradient, would invigorate the leaf, and also tend to protect it against parasites. Of course, wherever tin were suspected as being present, there wine growers must be conspicuous by their absence. As to the ferruginous flavour of Australian vintages, which is not always palatable to wine drinkers, no fear need be entertained on that score, for ironstone soil is not much met with in the F. M. S.—*S. F. Press*, 28.

CEYLON PROPRIETARY TEA ESTATES COMPANY, LIMITED.

The statutory meeting of the Ceylon Proprietary Tea Estates Company, Limited, held at the offices of the company, 20 Eastcheap, on May 18.

The Secretary having read the notice, calling the meeting,

The Chairman Mr. G. A. Talbot, said:—

This being the statutory meeting of the company which the Act demands must be held within four months of the incorporation of the company, I need not remind you it is a meeting at which no business can be done. I, however, may tell you that the various estates have been transferred to the company, and we are now in full possession of the same. When the prospectus was issued we had not been able to conclude negotiations for the purchase of the remaining one-eighth share of Radella Estate, but we have now done so, and there are only certain legal formalities to be gone through when this eighth share will be conveyed to the company. We have telegraphic advice that the crop for the first four months of the year has amounted to 290,000 lb. so that it would appear we are likely to fulfil our expectations as regards the estimated crop from our property when in full bearing, as set forth in the prospectus. As you are aware the first four months of this year have been unfavourable as regards exchange rates, but these are now improving, and we can only hope they may continue to do so. While in Ceylon in March last I visited Radella and Summerville Estates belonging to the company, and was thus able to confer with Mr. Wiggin, and Mr. Masefield, and advise them as to the future working of them. Mr. Wiggin, who was one of the principal vendors, and who is on the board of the company, is at present in Ceylon, and as he has a thorough knowledge of estate management will meet Mr. Masefield, who will have the care of the estates for the future, and arrange with him as to the working before he returns to this country about the end of the year. Should any shareholder desire to ask any question, I shall be very pleased to answer the same.

No questions being asked, Mr. W. R. Mitchell proposed, and Mr. G. T. White seconded, a vote of thanks to the chair, and the proceedings then terminated.—*H. & C. Mail*, May 21.

MULBERRY AND TEA CULTIVATION IN THE FAR EAST.

We take the following from the *Japan Times* of May 11th:—

According to statistics compiled by the Agricultural and Commercial Department, the area of land devoted to mulberry cultivation shows a tendency to increase annually as the result of the progress made in sericulture, the total area in 1896 being 288,937 *cho*. This is an increase of 22,772 *cho*, or 8.5 per cent compared with the previous year. The increase can be traced in almost every prefecture, those of Yamanashi, Yamagata, Gunma and Nagano being the most prominent examples. The total area of tea farms is 59,479 *cho*, being an increase of 1,750 *cho* or 3 per cent compared with the previous year. This is a result of the close investigations pursued in Shizuoka prefecture, on the one hand;

and of the remarkable improvement in the tea industry in Kochi and Miyazaki prefectures, on the other hand.

SOUTHERN INDIA TEA ESTATES COMPANY, LIMITED.

The following is from the directors' report to be submitted at the second annual ordinary general meeting, to be held at the office of the company, 16 Philpot Lane, London, E. C., on Wednesday next:—

The accounts show a net profit of £1,193 6s 9d after payment of debenture interest. Out of this sum an interim dividend of 5 per cent. was paid on October 7, 1896, and the directors propose now to pay a dividend of 5 per cent., making a total of 10 per cent. for the year, free of income-tax. The balance of £150 0s 10d will be carried forward to the current year. Without hitherto making a call upon the shareholders, the cultivated acreage has been increased by opening 96 acres of new land, which had been planted with good Manipuri seed and makes the total now 516 acres in tea. The purchase of the adjoining estates—Glenmary and Westerton—for £14,000, as from January 1, 1897, and as put before the company at the general meeting of October 7, 1896, has been concluded by the directors, and the transfer of these properties to the company duly completed; the vendors agreeing to receive payment in 500 fully paid-up 6 per cent. preference shares of £10 each and 900 fully paid-up ordinary shares of £10 each. The tea growing upon Glenmary and Westerton is of exceptionally good quality, and the purchase was recommended by Mr. Robert S. Imray, whose report upon them is in the company's office, and is open to the inspection of shareholders. The profits for the last season were £1,446 4s 5d. The acquisition of Glenmary and Westerton will give a compact property in one block with a total area of 912 acres of tea, 676 acres being in bearing. As a large area of valuable land belonging to the company is at present unproductive, the directors consider it highly desirable that some of it should be quickly brought under cultivation, which, with the company's staff of management and available labour, can be cheaply and profitably accomplished; and for this purpose it will be necessary to issue this year 300 new shares—say 200 6 per cent. preference and 100 ordinary shares, which it is proposed be first offered to the shareholders pro rata at £10 10s per share. Fifty acres are already felled in Kuduwa Karnum and eighty-six in Glenmary and Westerton for the present season's planting. The accounts from the gardens are of a more satisfactory nature than they have been since the company entered into possession of the properties. Mr. William Forbes Laurie retires in accordance with the articles of association, but offers himself for re-election as a director.—*H. & C. Mail*, May 21.

UDUGAMA TEA AND TIMBER COMPANY, LIMITED.

An extraordinary general meeting of this Company was held at the Registered Office of the Company, No. 20, Baillie Street, Fort, Colombo, this afternoon for the purpose of considering and passing the following resolution:—

That the capital of the Company be increased from four hundred thousand Rupees (R400,000) to five hundred thousand Rupees (R500,000) by the creation of 2,000 new shares of R50 each to be called "preference shares," entitling the holders thereof to a preferential cumulative dividend of eight per cent per annum, and in addition thereto in any year when the net profits of the Company after payment of debenture interest and after writing off such amount as the Directors of the Company think proper for depreciation, exceed the amount payable as eight per cent. dividend upon the "preference shares" that have been issued, one-third of such excess if all the 2,000 "preference shares" have been issued, or if all have not been issued, a portion of such one-third proportionate to the proportion that shall at the time have been issued of such 2,000 shares; and further entitling such preference holders, in the event of the Company being wound up, to be paid the amount of their preference shares in full before any payment is made to the ordinary Shareholders.

The original Shareholders in the Company to have priority of right to take up the preference shares pro rata to the number of shares held by each Shareholder.

The resolution was carried, all present voting in favour of it, with the exception of Mr. R. L. M. Brown who did not record his vote.

CEYLON TEA IN AUSTRALIA AND THE CONTINENT GENERALLY.

We are glad to welcome back Mr. Marinitsch, looking exceedingly well after his trip to Europe, and we learn that he brings good news of the progress of the sale of Ceylon tea throughout Austria. The demand for Ceylon tea is increasing, but he thinks that perhaps the demand for Indian tea is increasing in a larger proportion, and he considers that this is due to the Indian teas being better prepared. Ceylon tea, although of quite good enough quality for continental purposes, is not made so attractive as it might be, and in many parts of the continent "appearance" is the thing of greatest importance to secure a ready sale. Mr. Marinitsch thinks too that the Ceylon Tea Fund directors—and he speaks impartially never having received or asked for any contribution from this fund—would do better by advertising Ceylon teas on their own account, than by personal subsidies, which are too often expended in promoting individual businesses rather than for the welfare of Ceylon teas as a whole. We certainly consider, that the time is fast approaching when individual subsidies should be abandoned in favour of the wider and more impartial advertising of our teas.

REARING SILKWORMS IN THE PLAINS.—We regret to see that the experiment which has lately been tried, of rearing silkworms in the plains from cocoons imported from Assam, has had to be abandoned. The increased heat to which they were subjected in their new habitat proved too much for the worms, which gradually sickened, and died off in the course of a couple of years.—*The Statesman*.

“HOW TO ECONOMISE THE AVAILABLE LABOUR SUPPLY.”

Under this heading, we ventured, though with considerable hesitation, to trouble the planting community—some time ago—with a third Circular containing questions bearing on the all-important question of Labour Supply. Most of these were suggested by practical men for whose opinions we have the highest respect: but, nevertheless, we much feared that our “11 questions” would meet with the fate upcountry which they did from one Colombo merchant (with planting experience) who ought to be among the earliest to show a good example, instead of his reply to the Circular being,—“This is beyond me.” We are much gratified, however, to find a very liberal and most interesting series of answers already sent in from some of the most thoughtful and observant planters in the country and covering a considerable variety of districts. We, of course, expect a good many more and shall delay publication accordingly for a few days. That our Circular this time was rather a formidable one will be seen from its terms as follows:—

DEAR SIR,—It has been suggested that to bring together the opinions of a number of experienced planters on means of economising Labour on estates beyond the ordinary routine, might lead to some useful practical results. No doubt, there are labour-saving contrivances on some estates, not yet generally adopted, which it would be well to make known because every cooly saved is a matter of benefit to the whole community. Hints as to wire-shoots, spouting, &c., ought to be useful. It is also suggested that questions might be asked as to alterations in some points of present cultivation, weeding, draining, &c. We accordingly formulate a few questions:—

(1.) Have you had any experience of WIRE SHOOTS, or seen their working, and do you think them applicable much more freely than at present on estates? Do they damage tea leaf?

(2.) Particulars of any other Labour-saving appliances in field or factory of which you have had experience, or have noted among your neighbours?

(3.) Could small TRAMWAYS 18-in. or 12-in. gauge be applied profitably on average estates to save transport by coolies?

WEEDING.—It is pointed out that where clean weeding had been observed with coffee on steep land, it (the coffee) has gone together with the surface soil: and that most of the coffee still in existence is growing on rocky ground where a growth of mosses and low class plants—together with the nature of the ground—has allowed of fresh accumulations of leaf mould. What is suggested is that while all seeding or strong weeds should be taken out, there are others that—taking little out of the soil—might be left to aid in the formation and retention of humus. The questions then may be formulated thus:—

(4.) Has it ever struck you that weeding (both of coffee and tea) was overdone in Ceylon?

(5.) With reference to saving Labour as well as saving soil, would you advise an experiment in less frequent weeding, or in what may be called, selected weeding—that is the leaving of mosses, selaginellas, small ferns, and other such small plants?

(6.) Have you ever tried an experiment in cultivating any crop (of lupines, clovers—N.B., not the *Ovalis*, a common and obnoxious weed like a trefoil—) to be dug into the soil,—or would you advise such an experiment?

(7.) Is the present system of DRAINAGE satisfactory? Could any practical means be devised for trapping or retaining the vast amount of soil that is annually carried away with the surface water. A favourable account has reached us of the result of

planting rows of cuscus grass (which neither seeds nor spreads) above the drains—these grow close and strong, forming a barrier against soil being washed down, while allowing the rain to pass through?

(8.) Kindly mention any means in other directions in connection with the usual plantation work where Labour might be saved?

Next as to keeping Labour, would you

(9.) Suggest any special perquisites to coolies—is the giving of ground for gardens to each line generally observed—and where not, would it not make them more contented?

(10.) Would you advise the multiplying of boutiques or bazaars—until each two or three estates have their own—in order to prevent coolies wandering a distance and being tempted?

(11.) Are you troubled with a liquorshop in your neighbourhood and do you think labour would be saved if liquorshops were abolished, or reduced in number, in the purely planting districts?

Answers, opinions, or suggestions on all or any of above heads will oblige.

We can easily understand the younger Superintendents or Managers being reluctant to enter on so wide a subject; but apart from the fact that strict anonymity is preserved, there is nothing like “giving” as well as “taking” in planting discussions, in order that the fullest benefit from diverse experience, opinions and observations may be derived. The man who contributes—be it ever so little—a suggestion, opinion or remark on even *one* or *two* out of the eleven questions—is far the most likely to take an intelligent interest in the whole discussion and also to prove himself one of the leading planters of the future—we now refer, of course, to the younger generation of the community.

Meantime we must express our thanks to the gentlemen who have taken so much trouble to give us the advantage of their experience and opinions in reference to the important topics raised in our questions, while to those who have the Circular lying by them for the “convenient moment” we would say “Try and oblige by sending in your answers as early as possible.”

THE “BULKING OF TEA” ON THE ESTATE—IN COLOMBO STORES—AND IN LONDON.

The result of our enquiries goes to show that the “bulking of tea” in estate factories—where it can be done most conveniently and accurately—costs, if ordinary care is taken, such a mere fraction as to be practically *nil*; in the Colombo factory, the estimated cost is a half-cent per lb.—because boxes have to be opened and renailed, lead cut and resoldered, pieces of broken hoop replaced, etc.—while in the London warehouses the cost runs from $\frac{1}{4}$ d to $\frac{3}{4}$ d per lb. for whole or half chests. The comparison may be still further pursued by contrasting the following table given by our evening contemporary with the “half-cent” per lb. for Colombo, and the merest fraction (not worth counting) for estate bulking:—

The rates for taring and bulking in London (less ten per cent) are as follows:—

From 169 lb. to 199 lb.	2s	0d
“ 130 “	15s	1s 8d
“ 90 “	12s	1s 5d
“ 80 “	8s	1s 3d
“ 60 “	7s	1s 2d
“ 45 “	5s	— 11d
“ 35 “	4s	— 8d
“ 17 “	3s	— 6d
Not exceeding 16 lb.	—	4d

But it is not the mere money difference, so much as the treatment of our teas in the London

warehouses during the bulking process, that has to be complained of; and the undoubted fact that foreign substances—pieces of stick, dust &c.—get into the tea while repacking, excites the great objection to London bulking on the part of proprietary planters. There is indubitable evidence of this fact afforded—evidence which even Mr. Lipton cannot get over—in the gradual accumulation of tea up to a considerable quantity in the London warehouses. Where does such tea come from?—and what happens when a London buyer of tea finds that a chest is short weight of the quantity marked upon it? He lays the box on one side, telephones to the warehouse naming consignment, mark of chest and weight short; and at once a man comes up from the warehouse to see and test the case,—and as often as not with the short weight of tea in a paper package, so that he may at once close the complaint if a correct one! Again, where does this tea come from?—and how in the face of such an absolutely unjust and iniquitous system, Mr. Lipton's tea buyers can have the utter indifference to proprietary interests to say, "We will only buy London-bulked tea," surprises us beyond measure. Surely Mr. Lipton himself—as a Ceylon tea estates proprietor, a professed friend of the industry and of the colony—cannot have been consulted in this decision; and surely it cannot be one that is approved of by his experienced Agent on the spot (Mr. F. Duplock)? It is, moreover, quite evident that a whole community of careful, upright, fair-dealing men—the tea planters of Ceylon—are to be punished for the sake of a few "black sheep"—careless superintendents about their factory work—amongst them? This is neither politic nor equitable. We do not at all deny that there is a percentage—perhaps only a fraction of a per cent—of careless "estate bulking"; but surely it is not impossible for buyers to keep a note of the offending "mark" and take care not to buy that estate's tea—at any rate after a second faulty experience—ever again? We are the very last to defend the careless superintendent; although, we feel that, in some cases, the proprietor may have to share the blame in not granting a sufficiency of aid in factory work; and we know that there are cases in the experience of Colombo Agency houses which show downright neglect in the estate factory. One such case related to us, we may mention. A lot of 18 chests of tea is sent to Colombo Agents to be offered for sale; samples are drawn from three boxes; afterwards another sample for some reason is sent for and it proves so utterly different that an examination of the whole lot takes place when it is found that 6 out of the 18 boxes contain different and greatly inferior tea, although all were reported to be "bulked" the same. Now, in such a case, unless a satisfactory explanation was afforded, prompt and decided punishment should follow.

Nevertheless we maintain that the cases where anything like careless "bulking" occurs, are very few and far between. We know estates by the score—if not hundred—where, for a series of years, there has never been the slightest complaint in reference to "bulking." Now, why should such—the vast majority of—Ceylon estates be subjected to an additional tax, and their teas be depreciated in a London warehouse, because there are a few factories which are careless about their "bulking"? We think that, on reconsi-

deration, even Mr. Lipton's "house" will see its mistake. Certainly, we feel sure that Mr. Lipton himself—to whom we directly appeal as a proprietor with experience of Ceylon tea estates—will see the unfairness of subjecting a whole community of planters to the disadvantages which would follow were all the tea buyers to refuse to buy save on London "bulking." We would ask Mr. Lipton's London tea managers, therefore, to rescind their obnoxious rule and, instead, to take a note of any offending Ceylon estates' marks,—avoid them in the future, and, if they like, publicly report them, especially after a second offence.

BEE CULTURE AT THE SCHOOL OF AGRICULTURE.

Arrangements are being made for carrying on an experiment in Apiculture at the School of Agriculture, and a couple of hives especially constructed to suit the habits of the Ceylon honey bee under the supervision of Mr. Charles Andree of Kurunegala, who has had considerable experience in bee-keeping in Ceylon, may be now seen at the School.

PLANTING AND PRODUCE.

OUTLOOK FOR THE TEA TRADE IN CHINA.—A great expansion in the foreign trade of China is recorded by Mr. H. Kopsch, the Secretary of the Imperial Maritime Customs, in his report for 1896, but in tea there is again a considerable falling-off. The decline of China's trade in tea is no new feature. That has been persistently dwindling for years past under the competition of India and Ceylon. And as to its prospects, this is the best that Mr. Kopsch can say:—"That the resuscitation of the China tea trade is not regarded as hopeless is evinced by the formation of a 'Poochow Tea Improvement Company,' for the preparation of tea after the Indian and Ceylon methods." He does not regard it as improbable that in time this new departure will commend itself to the Chinese tea growers, and that although the market for China teas in the United Kingdom may never be recovered, an Asiatic demand for the finer qualities of them may slowly develop.

NEW SEASON'S CHINA TEAS.—The time has come round again for the opening of another season for China teas at Kinkiang, and we may soon hear of the first steamer leaving Hankow with new Monings for the London market. This commencement of the 1897-98 season, says the *Grocer*, does not possess anything like the same amount of importance to the home trade as openings of the season did years ago, when those teas occupied a far higher place in the estimation of the dealers generally than they do now; and after the losses and disappointments more recently experienced, it would be unwise to indulge in sanguine expectations of a very successful business in the article in the near future. Compared with the popularity it enjoyed in the "seventies," when the yearly consumption in this country averaged about 122,000,000 lb, China tea has gone almost entirely out of use—in 1896 only 19,831,680 lb were officially returned as having been consumed in the United Kingdom. The ordinary consumer's liking for this kind of tea has certainly died out; and it is only when Indian and Ceylon teas temporarily run short, and are relatively dear at 7d to 8d per lb for common quality, that the wholesale dealers, in the struggle to keep up a cheap (shilling) canister, will condescend to look at China descriptions. These then, by reason of their exceeding cheapness, become a tempting

bait to the mixers and blenders, who operate largely in them while the scarcity of other sorts lasts; and directly there is promise of a glut in Ceylon and Indian teas, and prices recede to their former reduced level, the dealers retire from the China division of the market and go back eagerly to their old favourites.

THE NEW MOVE IN CHINA.—Chinese tea importers are hoping that the tea trade of China will mend on the strength of the new manufacturing methods which are to be adopted. There are some tall stories current about the coming revolution in the China tea trade, but at present these reports are mere rumour. The *Grocer* echoes this hopeful anticipation. It says:—"Yet, notwithstanding all that may be observed to the contrary, there are still some old fashioned people who like China tea, and, preferring it to any other, will have it while it is at all possible; and for this class of consumers at least the beginning of a new season is decidedly hopeful. Especially is this so at the present time, when 'machine-made' teas from China will be subjected to their severest test. Till now they have been regarded merely as an experiment, having first come under notice in November last, when we spoke of them as showing 'an improvement on the old style,' also as being both 'strong and pungent,' and seeming 'to meet with approval.' If half what one hears of these teas be true, they are likely to prove the great feature of the coming season, and should be the means of partly restoring China growths to a healthier position than they have stood in for many years past. In manipulating China teas for native use or exportation, the worn-out plan was to dry the leaves as they were plucked, first in the sun, before finally preparing them for market; but it is said the new method recommended and adopted is to avoid the preliminary process of drying the leaf in the open air, and carry the freshly gathered leaves, full of their natural sappiness and moisture, straight to the pans or sheds for 'firing,' curing, and being 'machined,' preparatory to packing them for sale and shipment to foreign markets. China teas, which have become less and less a speciality with the home trade here, may, if made stronger by the new mode of manufacturing them, compete with the productions of India and Ceylon, the latter particularly; for, besides the newly-treated teas being more suited to the modern requirements of the British public of today, they are just what are wanted by shippers to the European continent and elsewhere, who must secure teas of some richness and strength, or they will not please the drinkers of the beverage there. Weak, flat, insipid, and thin-liquoring teas are, it appears, practically out of the running; and the smaller proportion they bear to the aggregate supply the livelier will be the demand and the more satisfactory the price for all teas of a finer and superior grade."

THE PROFITS ON THE SALE OF TEA.—The Chancellor of the Exchequer, in his recent speech on the tea duty question, hurt the feelings of some members of the tea trade by stating that grocers made large profits out of the sale of tea. The president of the Manchester, Salford, and District Grocers' Association has written to Sir Michael Hicks-Beach as follows:—"From this morning's papers I find that in the discussion in Parliament last evening as to a proposed reduction in the duty on tea you are reported to have said that 'the fact was, there was no article in the whole stock of a grocer that paid him so well. It was an article out of which he made his profits as largely and as certainly as the inn-keeper made his profits out of alcohol. The poor man would pay at the rate of 2s a pound for a small quantity of tea—tea which the wholesale dealer had bought at 9d.' As president of the Manchester, Salford, and District Grocers' Association, and a grocer having nearly forty years' experience in the retail grocery trade, I be of to offer a most emphatic protest against your remarks and an absolute repudiation of the above statement. As a matter of fact, a grocer would think

he was doing well to obtain 1s 4d per lb for tea costing 9d wholesale, but he would not thereby secure 7d profit to himself. To the first cost must be added 4 per lb duty, an additional tax of 1/4 per cent., cost of carriage, &c., making the cost to the grocer at least 1s 1 1/2 per lb. I may inform you that there are hundreds of retail traders in this district who purchase tea wholesale at 1s 2d per lb to sell again in small quantities at 1d per oz., or 1s 4d per lb. It is therefore most unfair to the shopkeeper to advertise him as selling at 2s per lb. tea which costs him only 9d.—I am, on behalf of the Manchester, Salford, and District Grocers' Association, yours, &c." On this subject Mr. James Little, of Manchester, writes as follows on the subject of the grocer's self abnegation:—"I don't suppose people will take much notice of the absurd statement of the Chancellor of the Exchequer re good and respectable trades-people robbing the public, because that is really what he suggests when he says tea dealers buy tea at 9d and sell it at 2s. Why, sir, the thing is preposterous. In these days of competition I sell tons of tea at 4d per lb profit. And a grocer if he got 2d profit would consider himself doing good business." —*H. and C. Mail*, May 21.

THE JAPAN TEA INDUSTRY.

The position which Shizuoka *ken* occupies in the tea industry of Japan may be easily gathered from the fact that out of 40,281,669 cattiees sent from various parts of the empire to Yokohama and Kobe in 1895, Shizuoka contributed no less than 17,274,937 cattiees, the amounts brought in during the same year, from other noted tea districts being as follows: Miye, 5,516,000 cattiees; Kyoto, 3,187,105 cattiees; Osaka, 1,858,959 cattiees; Shiga, 1,044,631 cattiees. Besides green tea, Shizuoka produces Oolong (Formosan) tea and black tea, the first, however, being predominant. The tea manufactured in Suruga, which province and Totomi make up Shizuoka *ken*, is collected in the local depots at Shizuoka, Fujiyeda, Numazu, Omiya, Yoshiwara, and Ejiri; while that manufactured in the other province is collected at Kanaya, Kakegawa, Futamata, Hamamatsu, and one or two other places. The leaf is next sent to Yokohama through the wholesale dealers of the respective places. In the city of Shizuoka there is the Nippon Tea Manufacturing Company, which sends goods to foreign markets without passing through the hands of foreign merchants in Japan. A special establishment for remanufacturing tea is also found in Jyoto Gun. The latest statistics on the Shizuoka tea industry are as follows:—

Area under tea cultivation ..	12,744 <i>cho</i> .
Annual output ..	1,600,000 cattiees.
Value of output ..	4,800,000 <i>yen</i> .
Members of Tea Guild ..	74,675
Licensed instructors in tea manufacturing ..	571

The rise of wages was during the last few years quite surprising. During 1895 the average daily wage of tea-pickers did not much exceed 12 *sen*, but was raised to 17 *sen* next year for men. At present wages paid to girls and women for picking do not differ from the rate of last year, but it is extremely probable that the tendency to increase will appear sooner or later.

The ruling price of the raw leaf being very closely related to that of manufactured, it is not yet possible to give any precise statement on the subject. But it is expected that this season the growers' price will be midway between that of 1895 and 1896, that is, between 33 *sen* and 23 *sen* per *kwanne*, and will range between 27 and 30 *sen*. Wages of tea manufacturing operatives have risen even at a greater rate than in the case of leaf pickers' wages. Two or three years ago the average rate of wages was about 30 *sen*, but last year it rose to 50 *sen*. But it is not the wages alone that tea manufacturers have to pay on account of their men; they must also supply food to the men, and at an increasing cost. The rise in the market price of charcoal must also be taken into consideration, for it constitutes

one of the most important items in tea manufacture. Two or three years ago a *yen* would purchase 22 *kwamme* of charcoal, but this year the purchasing value of the *yen* fell to 16 or 17 *kwamme*. With the general rise in the timber market, the price of tea boxes is also steadily going upward, probably to as high as 40 *sen* this year as compared with 35 *sen* last year. Such being the movement in the cost of production it is not surprising that tea manufacturers and dealers are very anxious about the outlook this season. The supply of leaf will not be deficient, for though in some particular districts the damage inflicted by the late frosts has been estimated to diminish the output by about 30 per cent, as compared with the yield of an ordinary year. The crop from the whole prefecture of Shizuoka is expected to exceed that of last year by 20 per cent. From the 2nd to the 10th inst. the first picking will be most active.—*Japan Times*, May 8.

[SECOND ARTICLE.]

Tea dealers and growers of Shizuoka *ken* are fully alive to the necessity of stamping out the ruinous tendency towards deterioration in the tea trade. Consequently, last year, when the tea market was unusually dull and when, therefore, according to previous experience, inferior goods were extremely likely to appear, people wisely decided to suspend the manufacture of tea altogether for the time. Tea manufacturers of Kanaoka-mura and its neighbourhood have decided this year to give up using iron pans in the manufacture of tea, the use of such implements tending to deteriorate the quality. There are several varieties of deteriorated tea, and these are made in different ways. For the sake of clearness, we may subdivide deteriorated tea into three classes namely "Fusei-cha," "Chakushoku-cha," and "Sosei-cha." There are commonly five different ways of making Fusei-cha, and they are (1) to use leaves resembling those of the tea shrub, or to mix such leaves with real tea; (2) to sprinkle black or dark-coloured sand, or other materials, in the tea, while the process of manufacture is going on, and thus to increase the weight of it; (3) to re-manufacture tea which has gone bad, and to use it either by itself or by mixing it with tea of good quality; (4) to convert coarse leaves of other trees or shrubs into "tea" by the aid of certain sticky substances, or to mix such bogus "tea" with genuine leaf; (5) other clever methods, which, however, are not so common as those enumerated above.

"Chaku-shoku-cha" is made (1) by colouring tea (after manufacture) with antimony or plumbago, or mixing tea thus coloured with ordinary tea, (2) by using sulphate of iron or other compounds of iron during the process of manufacture, to give the tea a black appearance.

"Sosei-cha" is (1) tea dried in the sun (black tea excepted); (2) tea made of coarse leaves rotted by various processes so as to give them a black appearance. (3) Rotten tea dried in the shade.

In enumerating these different varieties of adulterated and deteriorated tea and explaining the different ways of making it, we do not of course mean actually to charge the tea manufacturers of Shizuoka in particular with being guilty of these fraudulent practices, for people of other places, Yokohama, for example, are known to be guilty of the same offences. We merely make this statement to inform the general public how deteriorated tea is made, and how the Shizuoka people are setting their faces against it. Another article will bring this description of the Shizuoka tea trade to a close.—*Japan Times*, May 7.

[THIRD ARTICLE.]

The Shizuoka tea growers and dealers are thoroughly desirous of keeping up the reputation which the locality enjoys as the largest centre of the tea industry in Japan. While tea growers of other districts, disappointed at the small margin of profit

which the business has yielded during the last few years, are converting tea farms into Mulberry plantations, the Shizuoka men stick to the business with admirable perseverance. They have, for instance, invited from Formosa several experts in the manufacture of Oolong tea, and are trying to start a new branch of tea industry. All these efforts are most praiseworthy, but they seem to absorb the attention of the Shizuoka men too much, to the neglect of other important matters which lack the attraction of novelty. For instance, they do not seem to devote enough attention to the necessity of devising means calculated to reduce the cost of production which seriously threatens, according to the recent tendency of the market, to eat up whatever profit may be expected to accrue from the manufacture of tea. Indeed, the rate of increase of the producing cost during these few years far surpasses that of profit, as a glance at the following figures will show:—

COST OF PRODUCTION.

	1891	1895	Rate of increase.
Daily average wages of tea labourers	.. 30 sen	50 sen	66 per cent.
Price of charcoal per <i>Kwamme</i> 3.6	6.0	66 "
PRICE OF TEA.			
Average price of tea per 100 catties	.. 16.61 <i>yen</i>	22.86 <i>yen</i>	37.6 per cent.

The year 1895 was one of the most favourable years to tea growers, the market having stood at an unusually high level, and yet, even taking the figures of that year, the rate of increase of profit does not exceed 29 per cent, as compared with 66 per cent. increase in the cost of production. The point deserves the most careful attention of Shizuoka people. Various schemes thus far devised by them for the purpose of reducing the cost of production are mere temporary expedients and are of no permanent use. The primary point to be kept in view is the expensiveness of manual labour, the whole process of manufacture being at present entirely undertaken by human hands. Under the circumstances, a machine which Mr. Mochizuki, of Shimo, Aibara county, Shizuoka Prefecture, "invented" last year must be recommended to the notice of those who are interested in the tea industry. A set as originally constructed costs 250 *yen*, and the machine when operated with water power is capable of doing the work of 16 men, while only two men are needed for working the machine. The inventor has since thought it necessary to effect some modifications and the cost of the later pattern is consequently raised to 800 *yen*. He is contemplating the use of the machine this season at his tea factory, and the result ought to be carefully observed by all tea growers. Another point to be impressed on the tea growers, though already very well known to them, is the necessity of bringing foreign consumers of Japan tea and tea dealers and growers of Japan into closer touch, and to dispense with the service of intermediated foreign agents. For this purpose refring manufactories must be established in Shizuoka, instead of Yokohama and Kobe, as at present, and tea thus made to suit foreign taste must be shipped from Shimizu, instead of sending the goods to those two ports. Indeed, Japanese tea now passes through the hands of too many agents before it reaches its destination, and the point will at once be evident if comparison be made in this respect between it and Ceylon tea as follows:—

INDIAN AND CEYLON TEA.

(1) Consumers—(2) retail dealers—(3) American importers or wholesale dealers; so much with regard to the interior of America; (4) foreign exporters at Calcutta or Colombo—(5) producers; so much with regard to the interior of India; total 5.

JAPANESE TEA.

(1) Consumers—(2) retail dealers—(3) American wholesale dealers; so much with regard to America; (4) foreign exporters in Japan ports—(5) Japanese dealers at treaty ports—(6) local wholesale dealers—(7) local middle men—(8) producers; so much with regard to Japan; total 8.—*Japan Times*, May 10.

B. C. AFRICA CHAMBER OF AGRICULTURE, AND COMMERCE.

LABOUR AND TAXES.

Owing to numerous complaints with regard to the restrictions put upon Angoni coming to work in the Shire Highlands, an extraordinary Meeting of above was held in the Mart Blantyre on 22nd March. The Meeting was open to the Public, and a large number assembled, representing every interest in B.C.A.

The action of the Administration in requiring Planters and other Employers of labour to pay over to the Government the tax of 3s was strongly objected to; and exception was taken to the Collector's stipulating the wages to be paid to Angoni. After an animated discussion in which the majority of those present took part, the following resolution was unanimously agreed to:—"The Chamber having received many complaints from Planters and others regarding the scarcity of Angoni labour, and having learned that the chief hindrance lay in the manner of collecting taxes, pursued by the Government, and after evidence led, and discussion of the matter, is of opinion that"—

(1) "The time has not yet come for the levying of a tax of 3s per hut upon Angoni as levied in more properly civilized districts."

(2) "The manner in which this tax is being levied makes it a poll tax and not a Hut tax."

(3) "The restraining and arbitrary directing of Angoni labour practised by the Collector is (1) Out of form (the Collector should not be a labour Agent); (2) injurious to the Planting industry; (3) above all prejudicial to the freedom of the Angoni (practically making him a slave)."

(4) "The alleged intimidation by the soldiery and Police keeps the villages and gangs of labour in a state of terror, brings the district into the state of a conquered country instead of a Protectorate, and tends to create a block in the labour supply of the district."

(5) "In no case could the Employers of labour be asked to do the proper work of Government in practically collecting taxes for the Government. (6) The rate of pay to each labourer being so different in different districts it should be left to the free contract between Employer and Labourer, the Angoni's welfare being in every case the Planter's interest."

(7) "The difficulties put in the way of a free ferry across the river should be taken away and the River be free to anyone desiring to cross."

It was also arranged that a special committee should be appointed to draw up a letter to be sent to H. M. Acting Commissioner on the subject, along with evidence in support of the resolutions adopted.

ANOTHER CEYLON TEA COMPANY.

MOOLOYA ESTATES, Ltd.—Registered on May 12th with a capital of £50,000, in £10 shares to acquire and carry on the business of a tea planter, carried on by R. J. D'Este, in Ceylon, and to adopt an agreement with him. The subscribers are:—

	Shares.
F. S. Long, 10, Mincing Lane, E C, broker	.. 1
A. W. Edwards, 5, Newman's Court, E C, broker	.. 1
G. Pitman, do do do do	.. 1
A. Brown, 5, Dowgate Hill, E C, director	.. 1
J. A. Roberts, do do secretary	.. 1
R. S. Fairhurst do do clerk	.. 1
H. J. King, do do clerk	.. 1

The number of directors is not to be less than 2 nor more than 5; the first are R. J. D'Este, A. Brown, J. A. Roberts, and R. E. D'Este; qualification £1,000; remuneration, as fixed by the company Registered by Pitman & Sons, 14, Clement's Lane, London, E.C.—*Investors' Guardian*, May 19.

DARJEELING AND DOOARS TEA.

The second ordinary general meeting of the Darjeeling Consolidated Tea Company, Limited, was held yesterday, at Winchester House, E.C.—Sir Alexander Wilson (the chairman) moved the adoption of the report and accounts. The out-turn of tea for the season had been 456,586 lb., the general average price realised being 11 annas 6 pies per lb.

The gross profits amounted to £6,203, and the commissions to the agents and the managers absorbed £771. The directors recommended the declaration of a dividend of 4s 2d per share, which would take £1,250. With regard to the present season, an out-turn of 456,000 lb. was estimated for an area under cultivation of 2,200 acres.—Mr. Gibbons urged the desirability of the company's tea being sold in the home market instead of at Calcutta. The Chairman said the point would be carefully considered. The past year had been a disappointing one, and coming in as they did, the directors had not felt justified in upsetting all existing arrangements. Certainly the board had reason to regret the prices they had obtained for the company's tea, and probably their experience would enable them to benefit from the mistakes of the past.—The reports and accounts were unanimously adopted.

DOOARS TEA.—The directors' report for the year ended December 31 last states that the new gardens, Hilla and Grassmore, are nearly completed, though further expenditure is required during 1897, mainly for machinery. Hilla in 1896 yielded 187,305 lb. of tea and Grassmore 152,356 lb. On the company's gardens the year 1896 was fairly healthy, and no casualties occurred among the European officers. The weather early in the year was marked by drought and again in the months of June, part of July, and August. The total rainfall was much less than in 1895, a maximum of 130 in. being recorded at Bhogotope, as against 193 in. in 1895 registered at Hilla. The total out-turn increased from 3,017,945 lb. in 1895 to 3,025,366 lb. in 1896. In the tea market the prices were, on the whole, higher than during the previous year, and on the gardens a sustained effort was made to improve the quality of manufacture. The company's tea thus fetched an average of 8-26d. per lb., as against 7-52d. in the season of 1895. The average price of the Dooars district was 7-62d. The rise in the Indian exchange, whereby the company's remittances to India to meet the working charges cost 1s, 2 15-32d. for every rupee, as against 1s, 1 15-32d. in the previous year, has largely reduced the company's profits. The latest reports from the company's properties are favourable. The weather has been fairly good for tea, and the labour force is stronger than in any previous year. The net profit for 1896 is £29,954, to which must be added £245 balance forward from last year. After the payment of the preference dividend, the directors recommend a final dividend of 15s and a bonus of 5s., making, with the ad interim dividend already paid, a distribution of 12½ per cent, per annum on the ordinary shares. Of the balance the directors propose to carry £5,000 to the reserve fund, bringing it up to £45,000, leaving a balance of £300 to be carried forward.

THE AMSTERDAM CINCHONA-MARKET.

Our Amsterdam correspondent writes on May 17th that since the public auctions of May 6th, 193 bales of bark, representing 1,022 kilos of sulphate of quinine, have been sold privately at steady prices. A few parcels of *Succiruba* druggists' quill have also been sold.—*Chemist and Druggist*.

TEA PLANTING IN CEYLON.—Under this heading Mr. John Hughes contributes to last Saturday's *Field* an article of about a column in length, from which I may quote the concluding paragraph which illustrates the practical character of the teaching:—"To succeed as a tea planter a man must be energetic in body sound in constitution and have some scientific knowledge of the composition of soils and the nature of plant food, in order to produce the best quality of the green leaf while for the manufacture of such leaf into tea, further acquaintance with the principles of organic chemistry should be of great practical value and likely to assist in modifying the various operations according to special circumstances of the season's soil and situation of the estate."

EXOTICS AT KEW.

Of the many plants in blossom at the Royal Gardens, Kew, at the present time several are of special pharmaceutical interest. Among these are *Salanum crispum*, a bushy plant, native of Chili, known to the natives as Natri which, macerated in water, is used as a remedy for typhoid fever, either as a drink or clyster. *Ledum latifolium*, or Labrador tea, a plant of shrubby character, native of North America; the leaves are esteemed as a pectoral and tonic, and during the War of Independence were used as a substitute for tea. *Viburnum prunifolium*, the black haw or stag-bush of the Eastern United States, where it forms a much-branched shrub or small tree on rocky hillsides, is valued, for its edible fruits and its bark, which is used as a remedial agent in pregnancy and uterine diseases. The foregoing are growing in the open. *Brounea coccinea*, or Venezuelan rose, a shrub from 6 to 10 feet high, with bright scarlet fragrant flowers, which, together with the leaves, are employed by the Venezuelans as a laxative and the bark as a remedy for hemorrhoids, is growing in the palm-house, where will also be found *Saraca indica*, a small tree of the Himalayan region, Ceylon, and Malacca, and known to the Hindus as Asoka, and venerated by them as a sacred tree. The rich orange-coloured flowers, which gradually become red, are highly fragrant, and are employed for temple decoration. The bark is mildly astringent and acidulous, and is much used by native physicians in uterine affections, especially in hemorrhagia.—*Chemist and Druggist*, May 22.

JAFFNA A NEW SOURCE OF LABOUR SUPPLY.

A Matale correspondent writing under yesterday's date says:—

Today about a dozen Jaffna Tamil coolies entrained at Matale on their way to Dikoya. This is the first time Jaffna Tamils have been seen going to be employed as coolies on estates, and the newcomers will be watched with interest, as to their capability to compete with the Indian Ramasamy.

EASTERN AND CEYLON TEA ESTATES AND TRADING COMPANY, LIMITED.

Registered May 11th, with a capital of £20,000 in £1 shares to carry on in Ceylon, India, China, or elsewhere the business of planters and growers of tea, coffee, rice, cocoa, cinchona, tobacco, etc. The subscribers are:—

- S. W. Hayward, 82, Lower Thames Street, E.C., printer 1
 - E. Hayward, 82, Lower Thames Street, E.C., printer 1
 - J. van Baerle, Market Hill, Woodbridge, Suffolk, agent 1
 - A. E. Scott 21, Billiter Street, E.C., civil engineer 1
 - W. Brainc, 21, Billiter Street, E.C., book-keeper 1
 - F. Harvey, Central Hill, Upper Norwood, tea broker 1
 - J. Lornie, 79 Guildford Street, London, linen manufacturer 1
- Registered by H. McCraw, 61, Chancery Lane, W.C.
—*Investor's Guardian*.

OPENING UP A NEW COLONY.

The number of persons who are now going out to Mombassa, discloses the fact that the railway to Uganda is not only being well and quickly pushed on, but that the country is found to agree with the emigrants from India. At first it was

feared that they would suffer in the malarial districts from fever, and, doubtless, such was the fate of many; but the stay of the construction parties in the thick cane brakes and low-lying lands within a few miles of Mombassa is now nearly at an end, and miles upon miles of veldt are ahead of the track-layers through a rising country and an increasingly salubrious climate. Indeed, in some parts where the elevation rises from four to eight thousand feet, natives of India, save those from the North West or the Punjab, may find it rather too cold for pleasantness; but the European will be likely to consider it a delightful climate, and not only is it probable that the principal railway stations will be eventually removed from the terminus to some central locality, but that the coming colonies will arrange themselves naturally in the elevated districts, where it is cool, well watered and healthy.—*Indian Planters' Gazette*, May 29.

BRITISH NORTH BORNEO.

(*Official Gazette*, May 1.)
FROM ANNUAL REPORT ON PROVINCE ALCOCK.
(WEST COAST DISTRICT.)

The year 1896 has been a most prosperous one as regards trade; and a proportionate increase in revenue has followed. As contrasted with 1895 an increase of 51 per cent is shown; similar to that year over 1894.

AGRICULTURE.—Tobacco. The crop planted in 1895 and supplied last year fetched a much lower price than formerly, owing in a great way to the state of the market where low prices ruled. In quantity it surpassed the preceding year by 954 bales, for, although Banguay Estate closed Langkom Estate was reopened by the New London and Amsterdam Company and 170 fields planted. During last year, the season was a splendid one for planting. This crop throughout Marudn Bay, is an excellent one as regards quantity and quality of leaf; which is quite equal to that planted in 1894.

The following notes were taken during a visit made by me a few days ago:—

Estate.	Company.	No. of Fields.	Average yield for field.
1 Pitas,	German B. Syndt ..	130	8.50
2 Tandik,	N. L. B. Tob & Co.*..	250	10.17
3 Bongon,	ditto ..	200	14.42
4 Bandau,	ditto ..	250	10.07
5 Ranan,	ditto ..	250	10.82
6 Langkom,	N. L. & A. Co. ..	170	10.24
Total fields		1,220	Gen. Av. 10.70

* N. L. B. T. Co.'s average 11.35.

The crop of 1896 is therefore a great success and Managers are confident.

The returns of bales shipped from Province Alcock during the last nine years are as follows:—
1888. 1889. 1891. 1892. 1893. 1894. 1895. 1896.
130 800 2,664 6,466 4,890 4,497 5,060 6,014

The sad deaths of Messrs. Kamermann and Breitag, Head Manager of the London Borneo Tobacco Company, and Langkom Estate respectively were much felt by their numerous friends. Mr. A. F. Spruijt has succeeded the former and Mr. Van Leeuwen the latter. The Chinese, no longer attempt to plant tobacco at Kudat. The soil is too poor in the vicinity.

MR. CROLE'S BOOK ON "TEA."—A review of this new book will be found reproduced in our daily and *Tropical Agriculturist*. So competent an authority as Mr. John Hughes has given his opinion, that in respect of practical information for the purpose of the tea planter, Mr. Crole's volume is inferior to Mr. Bamber's which is published in Calcutta, and which we have made so widely known in Ceylon.

COFFEE.—The season for Coffee has been a good one. The increase of acres under cultivation on European Estates has not been marked, but a new estate at Mempakad has been opened under Mr. S. Murray, late of Taritipan Estate. Orders have been however received, to open 100 acres more at Taritipan and Mr. E. Walker of Mempakad Estate has commenced extending. At Taritipan, the supply of native labour, from Sulu, is increasing and Mr. E. Walker writes that he gets a fair amount of Dusun or Hill native labor at 17 dollars cents per day. This is the result of carefully treating the shy aboriginal and allowing them to choose their own hours of rest; looking at the work done at the end of the day as a gauge of industry.

The following figures are supplied by the Managers:—

Estate.	Super-intendent.	Piculs shipped.	Average coffee.	Coco-nuts.
Taritipan ..	E. Schuck	258	200	12
Mempakad ..	E. Walker	—	36	3
Victoria Estate..	H. B. Van Groenan	30	12	—
Kudat Gardens	Chinese	10	60	—
Great Valley ..	S. Murray	—	—	—

The cultivation of coffee by the Chinese is increasing monthly,

One Tobacco estate has given out an order for 1,200 seedlings and the manager intends to work the same with convalescent coolies.

There is a large quantity of land under dense jungle available for prospectors, with good soil and water access, in Melobang Bay, about 13 miles from Kudat, or up Melobang River, which steam launches pass daily.

COCONUTS, COCOA AND PEPPER.—Nearly all the Chinese near Kudat now plant coconuts, and areca-palms. Pepper is not extending owing to the low market prices but the existing vines are well set up. Cocoa planting is limited to Taritipan Estate. In Sulu, this plant has a luxuriant ground but the fruit is destroyed by a weevil, and I am afraid that the small extent of its cultivation in Murudu Bay will render it a prey to the same pest.

PLANTING NOTES.

“A MAGNIFICENT COFFEE CROP”—is the term applied by a good judge in such matters to the crop on an estate not a hundred miles from Nuwara Eliya. We hope there is to be a general good crop this season on the acreage remaining to us of our old staple, throughout Uva.—Since writing this we have seen Mr. Vicaresso who has a poor report of coffee on the Badulia side, the unusually wet season (23 inches of rain in April!) being fatal to the chances of a coffee crop.

“THE JAPAN TEA INDUSTRY.”—We direct attention to three short articles from a Japan paper on the above subject, given on pages 93-94. Interesting information is afforded and respecting one of the principal districts, if not the chief district, we see that the area of cultivation—we give the equivalent as well as well we can—is 31,113 acres and the annual crop 2,133,333 lb., a “catty” equalling 1½ lb. avoirdupois; but this gives only 70 lb. made tea per acre!

“COCA” AND “COCOA.”—Our contemporary of the “Examiner,” in a leading article written a few days back, refers to Cocaine as the product of the Cocoa tree. This error is surely unpardonable in a cacao or “cocoa” growing country like Ceylon? Cocaine is from the *Erythroxylon Coca*—a new product much discussed in Ceylon some years ago: see pages 132-133 of our “Planting and Agricultural Review” in the latest “Handbook and Directory.”

NOT BRITISH TOBACCO.—According to official reports, says the *British Medical Journal*, tobacco is adulterated with sugar, alum, lime, flour or meal, rhubarb-leaves, saltpetre, fullers’ earth, starch, malt-commings, chromate of lead, peat moss, molasses, burdock-leaves, common salt, endive-leaves, lampblack, gum, red dye, scraps of newspapers, cinnamon-stick, cabbage-leaves, and straw brown paper. This is an absurd statement, and possibly refers to the tobacco of some other country. Somerset House claims to assure us that the tobacco-supply of this country is amongst the purest of products consumed by the public.

THE COCOS-KEELING ISLANDS.—An epidemic of “beri-beri”; the loss of Mr. Ross’s trading schooner, which is supposed to have been stolen by a number of men who had been shipwrecked on the islands and were being sent back in her to the mainland; and the increasing nuisance caused by rats, are the main topics of interest touched upon during the last few years. To subdue the rats a number of cats were introduced, but they are so perverse as to leave the rats alone, and they are gradually destroying all the birds, including those which were taken to the islands to keep down the coconut beetles.—Local “Times,” June 5.

DATE PALM CULTURE.—There seems to be a run upon the cultivation of the Date Palm in the Jaffna Peninsula and we have several requests made to us for information. It is said, indeed, that Government is suggesting the culture; but we do not see why the Date should do so well as the Palmyra, or prove more useful, in North Ceylon. We quote as follows from the “Treasury of Botany” :—

The Date Palm, *P. dactylifera*, is cultivated in immense quantities all over the northern part of Africa, and more sparingly in Western Asia and Southern Europe; and in some of these countries its fruit, though only known by us as an article of luxury, affords the principal food of a large proportion of the inhabitants, and likewise of the various domestic animals,—dogs, horses, and camels being alike partial to it. The tree usually grows about sixty or eighty feet high, and lives to a great age, trees of from one to two hundred years old continuing to produce their annual crop of dates. Numerous varieties are recognised by the Arabs and distinguished by different names according to their shape, size, quality, and time of ripening. The fruit, however, is not the only valuable part of this widely dispersed tree, for, as with the coconut tree, nearly every part is applied to some useful purpose. The huts of the poorer classes are entirely constructed of its leaves; the fibre (*li*) surrounding the bases of their stalks is used for making ropes and coarse cloth, the stalks themselves for crates, baskets, brooms, walking-sticks, &c., and the wood for building substantial houses; the heart of young leaves is eaten as a vegetable; the sap affords an intoxicating beverage (*lagbi*), though to obtain it the tree is destroyed; and even the hard and apparently useless stones are ground into food for camels. Finally, we may mention that the Date was probably the Palm which supplied the ‘branches of palm-trees’ mentioned by St. John (xii. 13) as having been carried by the people who went to meet Christ on his triumphal entry into Jerusalem, and from which Palm-Sunday takes its name.

P. sylvestris, called the Wild Date, is supposed by some authors to be the parent of the cultivated date. It is common all over India, and, like the last, attains a considerable height. Large quantities of toddy or palm-wine are obtained from it, but the Asiatics, more skilful than the Africans, obtain it by merely cutting off the young flower-spike, by which means they do not destroy the tree. Date-sugar, so extensively used in India, is made by simply boiling the toddy,

MR. E. E. GREEN.—We congratulate this gentleman (and no less the Planting community) on his appointment by the Governor as “Honorary Government Entomologist.” The further liberality of the Government, in getting 12 additional copies of the “Coccidæ of Ceylon” to be placed in the Kachcheris situated in the planting districts, deserves recognition.

TEA BULKING.—We suppose the comparison as to bulking which was discussed yesterday may be summarised as follows:—

Cost on Tea Estate Factory	practically nil.
„ Colombo Stores	—average $\frac{1}{2}$ -cent per lb.
„ London Warehouse	equals to from 1.23 to .66 of a cent per lb., according to size of chest.

—in the latter case, of course, apart from the loss and depreciation of teas.

DARJEELING planters—says the *Indian Planters Gazette*.—need not trouble their heads as to over-production in their district. The following figures show that the Darjeeling crop remains steady:—

	Estimate.	Actual.
	Million lbs.	Million lbs.
1894 ...	8.01	7.07
1895 ...	8.06	8.25
1896 ...	8.38	7.81
1897 ...	7.64	—

Darjeeling should sell well this year, as the estimate of 7.64 million pounds, though small, is considered a full one, as gardens are going in for finer plucking.

A CEYLON PLANTER IN THE BENGAL TEA DISTRICTS.—

The P. & O. steamer “Nubia” which recently arrived from Calcutta, brought Mr. E. W. Hancock after visiting some estates in the Sylhet tea districts, where, he says, a great deal of new land is being put into tea. The new planting, however, has suffered much from drought, and a very large percentage of the cold-weather-planting (about Dec-1896) has died out, and even earlier plantings suffered severely. Later there was rain, and the bushes are now commencing to flush. There are remarkably fine bushes to be seen on some of the Sylhet “Bheel” gardens, he says—bushes planted 5X5. After six years, they are now one sheet of tea. The best gardens are planted with “Mampore” seed. There are some fine *jats* of Mampore on Phootullah and other estates in the district. Mr Hancock also visited Darjeeling, but the bushes there were as a rule small, and of poor *jat*. He leaves tomorrow for Hatton, on a visit to his estates and will be in Ceylon for a month or two.

LABOUR SUPPLY FOR COFFEE IN B. C. AFRICA.—

The following is the latest deliverance on the subject in the “British Central Africa Gazette,” Zomba, April 15:—

Our prediction that the month of April 1897 would witness a great influx of labour into the Shire Highlands, from the lake, from Central Angoniland, and other districts, has been fully verified. More than 4,000 labourers have come down within the last two months from Central Angoniland to work within the Shire Highlands. All of these are men who never before visited the coffee districts. The Anguru have also come in, in increased numbers, and Fort Maguire has also sent a considerable contingent of labourers who have never before been to work for fixed periods. Bandawe and the Usiska District have also sent in numbers of men. From time to time the remark is heard that, as plantations increase in the Shire Highlands we shall find the present easily procurable labour supply diminish. This is a view which we ourselves have never agreed with. The labour supply for the coffee districts of B. C. A. is inexhaustible, and every year the limits of the country from which the labour comes in gets wider as the news travels further that steady and satisfactory wages can be earned.

VANILLA AND “RHEA.”—Some instructive correspondence respecting both these products will be found on another page. One letter on Rhea seems to contradict all the loud talk about the great value of chemical processes, etc.

CACAO DISEASE IN THE MATALE DISTRICT: IMPORTANT INFORMATION FROM MR. J. R. MARTIN.—We take the following interesting statement from a letter addressed by Mr. Martin to our evening contemporary. No one in the island has a better right to give his opinion as an experienced Cacao planter and we are delighted to have Mr. Martin’s assurance that things are not so bad as generally painted in reference to this disease affecting the red—not the hardier yellow Forastero—cacao. Mr. Martin speaks with authority for Matale and he knows a good deal also about Dumbara; but we believe Kurunegala is the district most tried. In any case, it is clear that an Entomologist ought to have been at work on the “poochie” many months if not some years ago—and further, how valuable would be the knowledge and experience of Mr. Martin if made widely known to his brother planters some time ago. An “Agricultural or Planting Board” could bring to a focus all such information and could also take prompt action through its specialist towards checking the pest. Mr. Martin writes as follows:—

As far as Matale goes, I can assure you, that the acreage which has suffered at all, is a small percentage, whilst the great majority of the cocoa in the district is perfectly healthy. I do not know much of Dumbara, but I do know that the estate in which this disease first appeared in that district nine or ten years ago, last year gave the largest crop on record. Another point is, that whilst the acreage under cocoa is, if anything, diminishing, the export of cocoa is steadily increasing. The disease itself is, as far as I am any judge, nothing new, jak trees have always suffered from it, and probably jungle trees also. It certainly is not a root disease, as the tendency is to work upwards from a puncture, but if allowed to develop the sap becomes vitiated, and the roots thereby become unhealthy. There is, I think, no reasonable doubt that the disease originates with a *poochie* of some sort, which works in a way something like the coconut beetle, and it is to trace this *poochie* and learn how to destroy him that we require the aid of a scientist. The disease is practically confined to the Ceylon red cocoa, although there are instances in which forastero growing amongst diseased red has been attacked; but speaking generally, as far as we have gone, the forastero has shown itself able to resist the disease. It may be that in time, the red cocoa of Ceylon will be entirely superseded by forastero, if so the change will be gradual, and not such as to produce any crisis, and in that case we would be following exactly in the steps of the planters of the West Indies. Dr. Hart has proved beyond a doubt, that a cocoa exactly similar to our Ceylon red, was once extensively cultivated in Trinidad, but was gradually discarded in favour of forastero, principally, I believe, of that variety which grows the large yellow pod. I quite recently visited two estates in this district on which this disease was supposed to be worst. It did not strike me that either of them looked very bad, and on both the forastero was flourishing exceedingly. The disease taken in hand vigorously and in time, can at least be held in check. If the small bleeding puncture, which denotes the first attack, is at once cut clean out, the disease is checked for that time at least. Allowed to develop it becomes contagious, so that trees which are badly affected should be at once cut out almost, and forastero planted in their place. Forastero thrives excellently where the red has failed. I can instance a small estate treated in this manner in which the disease has been entirely stamped out, coolies being now sent round periodically to see if it is re-appearing. Your friend, therefore, who saw 50 and 25 per cent of his trees die out, and left them there to do their worst, rather gives himself away as a planter.

THE CHINA TEA TRADE.

It is greatly to be feared that the foreign tea trade of China is virtually a thing of the past. As was predicted in these columns, year after year, as the export tables from Calcutta and Ceylon showed an ever increasing development of the crops in Assam and the Spicy Island, the time was approaching when the taxation in China would prove to be the destruction of the trade. These warnings all passed unheeded: the Chinese pursued, with undisturbed equanimity, their fatuous policy of killing the goose that laid the golden eggs; and could not even be diverted from that fatal course when it was clearly evident that the final extinction of the English demand was imminent. A fatality seems to hang over this valuable trade in the Central Kingdom. Not only have the high officials shown utter indifference to its gradual decay: even the sagacious and clear-headed Inspector-General of Maritime Customs, parting for once with his accustomed prescience and prudence, only preached improvement of cultivation and preparation instead of strenuously advocating a large reduction in the burdens laid upon it. The result is seen now in the almost total cessation of inquiry for the British markets. The total export of tea from China direct to Great Britain in 1896 was only 219,409 piculs as compared with one million piculs in 1885. This season the production of Hankow and Kiukiang teas is much heavier than last year and it is estimated the first crop alone will be about 55,000,000 lb. Ordinarily the decline in the British demand has been made up to a considerable extent by the increase in the Russian demand, but it is stated that Russia is now over-weighted with a heavy stock and will not be able to take more than half the above quantity, leaving 27,500,000 lb. to be shipped to England and America, against 18,500,000 lb. exported thither last year. Seeing that this is an increase of some ten million pounds, it is obvious that prices will rule at very unremunerative rates. Yet we presume there will be no reduction in the taxation that crushes the life out of this industry. In some notes on the tea trade of Amoy for last year supplied to the British Consul at that port for incorporation in his annual report Mr. Frank Cass gives some interesting details of the duties imposed on tea. He says that the crop of Amoy Oolongs in 1896 amounted to 1,200,000 lb., a shortage of 55 per cent on the previous year, and adds that "an equally marked decline is expected in 1897, after which the article will probably cease to appear as an item in our trade returns, as the tea districts are being rapidly thrown out of cultivation, and most of them are irrevocably ruined." Mr. Cass rightly says the reason is not far to seek. The entire crop realised \$136,000, while the lekin paid amounted to \$20,000 and the export duty to \$35,000, or a total of \$55,000, considerably more than one-third of the value of the tea. The Japanese Government, with characteristic foresight, last year reduced the export duty on tea in Formosa to \$1.12 per picul as compared with \$5.82 per picul imposed under the Chinese régime. This example will, of course, be quite lost on the Chinese Government, who never seem to learn anything either by the teachings of experience or by the successes of others until it is too late to profit by them. The shadow of this great loss has been impending for at least two decades, and there is literally no excuse for the crass folly which has permitted this valuable trade to dwindle to a mere nothing. The production of Amoy tea in the season 1876-77 was 27,200,000 lbs., and in 1896-97, twenty years later, this had fallen to 3,600,000 lbs! We entirely agree with Mr. Cass in the opinion he expresses—which he adds is that of the very highest experts—that all the machinery in the world will not now save the China tea trade unless a complete amelioration of taxation accompanies its introduction. And, as we have remarked before, it seems as vain to expect the Chinese mandarin to relinquish exactions on trade as for the Ethiopian to change his skin.—*China Overland Trade Report, May 29.*

"PLUCKING, PRUNING AND THE PREPARATION OF TEA."

We call attention to the following review by Mr. John Hughes of the recent prolonged discussion in the *Observer* on the above subject. No doubt Mr. Hughes reflects to a considerable extent, current opinion among thoughtful tea men at home while also giving us his own scientific views:—

The letters on the above which have appeared from time to time in the *Ceylon Observer* have offered very useful, instructive and interesting reading to all who are concerned either directly or indirectly in the Ceylon Tea Industry. The question as to the causes of the falling-off in price is essentially one for the serious consideration of planters and proprietors with the aid of tea tasters and brokers. If the fall be due to overproduction the remedy is an extended demand produced by the opening up of new markets. If, however, the falling-off in price is due to coarse plucking, injudicious pruning and careless manufacture, the complaint assumes a serious aspect and demands a fuller inquiry. If it be true that, notwithstanding the admittedly increased production, the prices for Indian Teas have not fallen to anything like the same extent as that experienced by Ceylon Teas, the existence of defective preparation or soil exhaustion must be regarded as proved.

In an article on "Tea Planting in Ceylon," specially written for *The Field* and published in the issue of May 15th, the writer has directed attention to the importance of getting young men with a special knowledge of Organic Chemistry to superintend the operations in the factory. Also of getting men as out-door superintendents who have a good knowledge of the art of judicious pruning and the requirements of the Tea Shrub in the matter of plant food with due regard to the composition of the soil.

It has been stated by one correspondent that the Indian Tea Companies have already recognised the value of employing as factory superintendents men who have had a special Chemical and Scientific training, and the improved quality of Indian Tea is largely attributed to greater skill and care in the manufacture. Hitherto Ceylon has not been wanting in enterprise and the continued energy and perseverance that the planting community have ever exhibited through years of great difficulty and doubt, certainly warrant the belief that at the present time a new departure will be made as soon as the practical need is recognised. It is obvious that different circumstances of season and soil must require a certain amount of variation in the manufacture of the leaf, and that the control of the Tea house should not be left in the hands of a native who is naturally incapable of judging to what extent variation in the treatment of the green leaf *should or should not* be made. It is acknowledged that from April to the end of June or July the quality of Ceylon Tea is inferior, while from August to November the arrivals are of a very different and generally superior quality.

The difference in the rainfall is no doubt the primary cause of differences in the quality of Ceylon Tea at different times of the year, but it would be interesting and probably practically useful, to ascertain the actual extent of the variation in the quality. In other words what are the properties of good tea as opposed to inferior tea. To what extent do the active constituents vary in quantity, and the respective percentages of Nitrogen, Phosphoric Acid and Potash in the different qualities of tea.

If the differences in the samples were clearly determined, it would be possible to supply in the form of manure the ingredients shown to be necessary.

Now that so many of the private estates are incorporated into public companies it is more likely that chemical experts will be attached to the large Tea factories, and when satisfactory results are shown in higher prices for the tea prepared, we may expect a great improvement in the whole system of manufacture as well as in the more scientific treatment of the growing shrub.

In the hope of hastening this more systematic treatment of the leaf these lines have been written, and if careful inquiry into the subject be the practical result, they will not have been written in vain.

JOHN HUGHES, F.I.C., Agricultural Analyst.
London, E.C., May 28th, 1897.

BRAZIL COFFEE NOTES.

The coffee production of the municipality of Ouro Fino, Minas Geraes, is said to be 307,000 arrobas.

A telegram says that in S. Paulo the fall in coffee is attributed to exaggerated estimates of the crop of that state.

The *Cidade de Campinas* says that it is informed by planters of western S. Paulo that the coffee crop has been very much injured by drouth. This will perhaps help to counteract the alleged exaggeration in estimates.

We hear that negotiations are still going on for the purchase of coffee plantations in Sao Paulo. One prominent planter cordially welcomes the movement. He says the English will not only bring in improved methods of cultivation and preparation, but will secure better prices for the product. All this he considers will be of great benefit to the country.

It is a noticeable circumstance that the coffee exporters are obliged to maintain a special force of watchmen to protect their property at the D. Pedro II docks. The thefts were on such a scale and were committed so persistently that no other course was open to them. The police did nothing, and the administration of the docks also did nothing. Although the thefts have not been wholly suppressed, they have been largely checked, but at a very considerable expense. This is met by voluntary contributions by the coffee shipping firms with but two or three exceptions. Until the authorities adopt some effective measure to protect the exporters, they must continue to maintain their own watchmen, and in this every coffee shipper should cheerfully join, onerous as the tax may be.

—According to Alexander von Glehn's coffee circular for March, the reports of the new crop are decidedly conflicting. The circular says that on March 4th Messrs. Kriische & Co., telegraphed that the next Rio crop would be 3 to 3½ millions bags and the Santos crop 4 to 4½ millions. On the following day Messrs. Steinwender, Stoffregen & Co. telegraphed that the two crops would aggregate 6½ millions, "under the most favourable circumstances." On the same day Messrs. Goetz Hayn & Co., estimated the next Santos crop at 3½ millions.

—There is in course of formation at Hamburg a new Company under the name of Colonisation Company for South Brazil, Limited, with a capital of 1,500,000 marks. The operations of the Company will comprise the sending and settling of German emigrants in Brazil and the supervision of the Colony. The new concern will also obtain the concession for a railway from the coast of Sao Francisco bay via the German Colonies Joinville and Blumeneau, to Desterro. The present juncture in Brazil does not appear wholly favorable for an operation of this kind. —*Financial News*, March 31.

BRITISH INDIA RUBBER AND EX- PLORATION COMPANY, LIMITED.

Share capital £2,00,000, in £200,000 shares of £1 each. There is also an issue of £100,000 six per cent. first mortgage debentures of £50 each. This company has been formed to acquire and develop 320,000 acres of rubber-growing territory, about thirty-five miles north of Cape Coast Castle. The vendor takes £250,000, payable in shares, debentures, or cash, or partly in either of them at the option of the directors, "but so that the vendor does not receive more shares than will enable the company to comply with the regulations of the Stock Exchange." This is a somewhat disingenuous manner of stating that, as a minimum, the vendor will receive £133,333 in cash.

The prospectus is very unsatisfactory, and the public will be well advised not to apply for shares on the very vague reports and still vaguer estimates of the company's prospects and profits. —*Daily Chronicle*, May 26.

SCIENTIFIC GARDENING EXPERIMENTS.

"BACKWARDS AND FORWARDS."

The *Gardener's Chronicle* has an article opening as follows:—

We hear a good deal about progressive evolution now-a-days, and it suits our complacency to dwell upon it. We look back to the days of our forefathers, and plume ourselves that we live in times when Palms and Pineapples are sold on costermongers' barrows, and when many things once unheard of, or only as the luxuries of the wealthy, are now in common use. So far good, there has been marked progress in gardening as in everything else. But it is as well to recollect that reversion may and does occur as well as progress, and, therefore, that it behoves us, whether "practical" men or students, to ascertain so far as we are able the influences at work which will result in improvement, and those which, if unchecked, will tend to deterioration. Two articles in our last and present numbers illustrate very aptly the state of affairs. On the one hand, we have the Director or Kew tracing, with the aid of specimens furnished by Messrs. Sutton, the progressive development of the Cyclamen; and, on the other, we have Mr. Francis Galton asking, for scientific purposes, what plants it would be most suitable to observe, and how to manage them, so as to bring about, in the shortest and most complete manner, the reversion to the primitive condition? We learn as much or more from our failures as from our successes, and on this principle we shall profit by the practical demonstration of the causes which lead to degeneration. Thus, an investigation which seems at first to be of a purely abstract character, is soon seen to be eminently practical.

—**SPRING VALLEY COFFEE CO., LD.**—This Company has been less fortunate than its sister one of "Ouvah," inasmuch as it did not start "tea" at so early a date; and now the alternative is offered to the shareholders of going without dividends for 3 or 4 years or raising fresh capital, thus:—

"That the capital of the Company be increased to £100,000 by the creation of 2,000 new shares of £10 each, to be called preference shares, and to confer on the holders thereof the right to a fixed cumulative preferential dividend at the rate of £6 per cent per annum on the amount for the time being paid up on such shares, and such preference shares to rank, both as regards capital and dividend, in priority to the other shares."

We have no doubt this resolution was adopted on 4th June. The dividend for last year was 2½ per cent.

PROGRESS IN THE KNUCKLES.

THE MONSOON A FRAUD—NATIVE AND ABANDONED COFFEE LANDS OPENED WITH TEA—FINE CARDAMOM FIELDS—THE KNUCKLES ROAD.

KNUCKLES, June 10.—Extraordinary weather here. The hills have been quite distinct and weather as hot as possible for the last 4 days. Last night we had a very heavy thunderstorm, the rainfall measuring 2.60 inches, the thunder and lightning being grand. Considerable tracts of village lands are being opened for tea. This year especially several large clearings have been commenced both by natives and Europeans. Of abandoned coffee lands there must be still quite 1,500 acres in the district and with tea at present prices I don't think owners are very anxious to extend. The district has now some very fine cardamom fields and this product is being extended wherever the land is suitable. The large new factory on Madakelle estate is now nearly completed. The Panwila-Knuckles cart road is in a very bad way and we are hoping the new Road Officer will put things in order. No gravel has been laid down for years.

MR. LIPTON'S TEA MANAGERS IN LONDON WISHING TO IMPOSE A TAX OF £50,000 A YEAR ON CEYLON PLANTERS!

What tea bulking in London would cost the Ceylon planters, if all their tea were bulked in the home warehouses as Mr. Lipton's tea managers would seem to wish, may be shown as follows. On an average 20,000 packages of Ceylon tea are sold in Mincing Lane weekly and the cost of bulking in the London warehouses may be taken at 1s per package. This means £1,000 a week or say a LOSS OF £50,000 A YEAR which the policy of Mr. Lipton's Tea Managers would entail on the tea planters of Ceylon!—for the cost of bulking tea in the estate factories is practically nil.

Surely, after this demonstration of what it practically means to Ceylon, Mr. Lipton will cause the obnoxious circular to be withdrawn.

DRUG REPORT.

(From the Chemist and Druggist.)

London, May 20.

QUININE.—On May 19th the prices of most quinine salts of Whiffen's make were advanced by ½d per oz. The present quotations of Sulphate in 100-oz. lots are 9d for bleached and 8½d for unbleached; 25-oz. and 50-oz. lots are quoted ½d; in smaller quantities ½d above these prices. The Hydrochlorate is quoted at from 1s to 1s 0½d per oz. These prices apply to salts in bulk. The proprietors of Pelletier's quinine inform us that their quotation for vials is not 1s 4½d, but 1s 2d per oz. for so-called "English shape." The Brunswick factory has also raised its price for bulk quinine from 9d to 9½d per oz. The position so far as the other makers are concerned is somewhat puzzling. Howard's brand is still nominally quoted at 9d per oz. for bulk, but the makers decline to sell to speculators. The B. & S. and Auerbach agents have no quotations, but are expecting early instructions from their principals. About 30,000 to 40,000 oz. of second-hand German quinine are believed to have changed hands at 9d to 9½d per oz. on the spot, and at 9½d per oz. for June delivery. The accuracy of the last-mentioned transaction is doubtful, and there are those who say that even now an offer of 9d per oz. would not be refused for fairly new spot stuff. The market, however, has certainly a very firm tone.

VANILLA.—All varieties remain extremely firm, and there does not seem to be any likelihood of lower prices through eth summer. It depends upon the position in Mexico, where stock are extremely low. The supplies of Mexican vanilla in New York are also very small.

COCAINE.—Firmly held, and not unlikely to be raised in price shortly. Sales of Hydrochlorate are reported to have been made at 9s 6d and 9s 9d per oz. There

are now (according to the British Consul) no fewer than ten cocaine factories in Peru. Of these, one is situated at Callao, two in Lima, five in Huanoco, and one each in the Puzuzo and Monzon districts. The following figures show the exports of crude cocaine and cocoa-leaves from Peru during the last six years for which statistics are available:—

	Year 1895	Year 1894	Year 1893	Year 1892	Year 1891	Year 1890
	kilos.	kilos.	kilos.	kilos.	kilos.	kilos.
Cocaine :	3,407	4,716	2,357	4,550	3,215	1,730
Cocoa-leaves :	—	372,360	390,955	338,465	128,543	—

CROTON-SEED continues to arrive, and the probabilities are that rather lower prices will shortly be seen, as this article is one of small consumption and can easily be over-supplied. The "Staffordshire" has brought 11 bags from Colombo this week.

PLANTING NOTES.

CACAO DISEASE.—A well-known planter thinks that we and others, in treating of this trouble, have not drawn a sufficiently wide distinction between the common Red variety (which is the one chiefly attacked) and the Forastero (which escapes or recovers). But our friend is mistaken: we especially drew the distinction in writing a few days ago. We quote from the letter as follows:—

In dealing with the matter you seem to class the two varieties "Common Red" and "Forestero" as one, or at any rate I don't think you have shown enough distinction between the two. I know of two or three persons who only cultivate the latter variety and as "Forestero" is not affected to the extent that apparently "Common Red" is, why should the value of a property in the one be lessened owing to the misfortune attending the other? Forestero cocoa may get this "canker" or "poochie" or whatever you like to call it. So do jungle and other trees, but like them very quickly throws off the disease or is not affected to any extent.

THE "AUSTRALIAN BAMBOO" USEFUL IN CEYLON.—We omitted to notice one interesting passage in Mr. Kellow's letter: it is where he refers to what we think might be called popularly "the Australian bamboo," although it is known in South-Eastern Enrope as "the Danubian reed." Here is the passage in Maiden's book which Mr. Kellow wished to see quoted:—

THE BAMBOO METHOD OF PLANTING.—MR. J. E. Brown advocates the raising of wattles in bamboos. The raising of trees by this means is common in India, and has been successfully carried out in South Australia. In India the true bamboo is used because it is abundant. In South Australia a large South European reed* (*Arundo Donax*, Linn.), which locally bears the name of "bamboo," is used instead. The reed is cut to 4 inches in length, by means of a small circular saw driven by hand or water-power. Endeavours are made not to include joints in the pieces cut, but if one should occur it is bored through. The pieces are packed together upright, filled with soil, the seed put in and allowed to remain there till the planting season. The seedling is transplanted in the "bamboo" just as it stands, and in cases where the bamboo is not sufficiently rotted, they are split up, in order to allow the roots to expand. Hundreds of trees thus start their careers, and can be transported in one small box—a brandy case for instance.

Mr. Kellow's own experience of this "Arundo Donax" is:—

The reed *Arundo Donax* referred to, grows here freely and when once established, will give an annual cutting of stalks from 12 to 20 feet long; besides being useful for plant raising, they make very neat temporary fences, warrachies for lines or split up into pegs for lining.

Clearly this is one more useful introduction which ought to be generally known in the higher districts.

"WATTLES AND WATTLE-BARKS."
IS THERE SCOPE FOR A NEW INDUSTRY
IN THE HIGHER DISTRICTS OF
CEYLON?

WE direct attention to a suggestive letter on this subject from Mr. A. J. Kellow of Albion estate, Wilson's Bungalow, who has perhaps given as much attention to the discrimination and utilisation of the different Australian acacias as any other planter in Ceylon. Mr. Kellow has long been an ardent advocate of the planting of "acacia decurrens" which, he maintains, does not run from the roots after the fashion of the more familiar "A. melanoxylon" and "A. dealbata," both so common in Nuwara Eliya and its neighbourhood. The wood of "A. melanoxylon" is so good for a variety of useful purposes, even up to cabinet work, and the tree is such a quick-growing one, that no one need regret its introduction where land is to spare; but it can be very troublesome in or near tea fields. The late Rev. W. Oakley was accustomed to show a very handsome bookcase—almost as well marked in the grain as calamander—which he had made from the timber of "A. melanoxylon" grown at Nuwara Eliya. In Mr. Maiden's valuable Monograph on "Wattles and Wattle Barks," the following is a part of the reference to this tree, the immediate purpose being to discuss the value of its bark:—

Acacia melanoxylon, R. Br., B. Fl., ii, 388.

The "Blackwood," but also known as "Lightwood" and occasionally as "Black Sally," "Hickory," "Silver Wattle."

The bark of this highly valuable timber has usually gone to waste after the wood has been obtained from the logs. "The bark is however, rich in tannic acid, and ought not to be left unutilised, though no trees of this species should be sacrificed for the sake of their bark alone." (Muller). A sample of bark from Monga, near Braidwood, N.S.W., yielded the author 11.12 per cent of tannic acid, and 20.63 per cent of extract.

But our chief business at present has to do with the non-running "A. decurrens" and its ready growth in our hill-country and the very considerable value of its bark for tanning purposes. As regards the tree itself there is no need for the present that we should reproduce the learned botanical description of the five recognized varieties. We content ourselves with a few sentences as to the variety Mr. Kellow himself has no doubt in view, namely "Acacia decurrens Willd.," the technical description of which is as follows:—

A handsome tree, glabrous, or more or less tomentose pubescent. (B), *et seq.* Branches more or less prominently angled, sometimes almost winged. Pinnæ, 8-15 pairs, or sometimes even more, rarely reduced to 5 or 6. Leaflets (pinnules) very numerous (30-40 pairs or even more); linear, from under 2 lines to nearly 5 lines long, according to the variety.

Flower heads small, globular, in axillary racemes, the upper ones forming a terminal panicle. Flowers, 20-30 in the head, mostly 5 merous. Calyx short, broadly lobed, ciliate. Petals, with slightly prominent midribs. Pods, usually 3-4 inches long; about $\frac{1}{2}$ inch broad or rather more. More or less contracted between the seeds. Seeds ovate (B), small as compared with those of most other arborescent acacias. A more popular reference runs:—

THE ACACIA DECURRENS GROUP OF WATTLES.—The well-known feathery-leaved wattle, familiar to most people in the eastern and southern colonies,—by whom it is chiefly known by one of two names, viz., black or green wattle—was first botanically described by the botanist Willdenow, who defined two species, *Acacia decurrens* and *Acacia mollissima*.

In the Flora Australiensis, Bentham took Willdenow's *decurrens* as the typical species, reducing the other species to the rank of a variety under the name of *mollis*; in other words, *Acacia mollissima*, Willd., is *Acacia decurrens*, Willd. var. *mollis*, Benth. Bentham also called another variety *normalis*, a third one *pauciglandulosa*, and a fourth (doubtfully) *Leichhardtii*.

A. decurrens is an important tan-bark in most of the colonies, and as the tree grows in the poorest soils, every encouragement should be given to its cultivation. Baron Mueller recommends planting of *A. decurrens* in worn-out lands overrun with sorrel. It is fond of moisture, and not of too much heat. The Baron also gives its rate of growth as about 1 inch in diameter every year. Mr. J. E. Brown mentions some trees in South Australia 30 feet high and 8 inches in diameter, only five years of age, and I can record similar experience near Sydney.

Mr. Kellow has had practical experience not only of the growth of "A. decurrens," but of the utilization of its bark for the use of Colombo tanners; and we gather that he has been paid as much as at the rate of R140 per ton for his consignments. He does not mention his outlay in harvesting, drying and transporting the bark; but this is not of so much consequence, because for any one taking up the industry on an appreciable scale, clearly the boiling-down process would have to be adopted to save the cost of carriage, which Mr. Kellow reminds us is equal to R25.46 per ton from Nannoya to Colombo. This boiling-down process is the more valuable, because, as Mr. Kellow mentions, branches and prunings (mere trash) can be fully utilized as well as the stem bark. Maiden's reference and account are as follows:—

The preparation of extracts causes an immense saving in freight, but an extract is chiefly valuable in that it enables us to utilise everything. The following is an account of a process as carried on in South Australia at the present time, and is suggestive:—"Messrs. Barrow and Haycroft have established at Echunga a manufactory of tannage, which, from the methods employed, is almost pharmaceutical. About 10,000 tons of wattle bark are sent annually from South Australia alone, and it is calculated that the waste in stripping is about four times this amount. The new factory converts the branches, too small to pay for stripping, into a strong fluid extract called tannage, which contains water 60 per cent., and soluble tannin 38.2 per cent., according to an analysis by Mr. G. H. Hodgson of samples from the first 80 tons recently shipped to England. The wattle 'trash' yields 12 to 16 per cent. of tannage. Two men can often cut and load 5 tons, and the waggons can bring in two loads a day, equal to 5 or 6 tons; and at the price (£1 a ton) which the firm is paying for thinnings and tops and branches, so much is offering that the patentees are obliged to distribute their order. The trash is tied up in large bundles and carted into the factory. It is then weighed, close beside the machine which cuts it up into 'chaff.' This machine is very much like an ordinary steam-plane, the chisels revolving at a high speed, and cutting through 2½-inch saplings quite readily. The chips are shovelled into large wooden hoppers, into which steam is introduced from a large Cornish boiler. There are three steam-heated vats, and the liquor is transferred from one to the other, pumped into elevated tanks, and thence allowed to flow from a tap on to steam-heated evaporating pans, about 30 or 40 feet in length. The evaporation is so rapid that in traversing the pans from the one end to the other the liquid is converted into a thick, tenacious, treacle extract. At the end of the pans it flows into a cistern, and thence by a kind of treacle gate into the casks, each of which will hold about 10 cwt. All that now remains to be done is paste on a label, put in a bung, weigh the cask, and send it off to market. In the process of evaporation a certain portion of the

acid is destroyed. The plant can be easily moved from place to place. It does not pay to cart the trash far, but a few square miles of wattle country will keep a factory going. The utilisation of thinnings allows the cultivation of the tree thickly on waste ground, and to begin cutting the third year. European tanners are quite accustomed to the use of such extracts, but it is said that it will be very hard to introduce it into the colonial tanneries."—(*Chemist and Druggist*, 1885.)

These words are still in successful operation, although mucilage still gives some trouble. Wattle twigs are rich in gum and mucilage, and some cheap process, which will get rid of these substances and leave the tannic acid uninjured, is a desideratum. I have received many inquiries as to whether the difficulty has been overcome, but I have had to reply in the negative, as far as a commercial process is concerned. There is very little gum in clean-grown bark, but far more in chopped twigs; extract will not be made from the former except in almost inaccessible districts. Of course, the extract in all stages of its manufacture must be preserved from contact with iron. Wooden vats are employed, and the heat for evaporation is obtained from hot water or steam. The waste bark, chips, &c., used in the preparation of the extract are first digested in cold water, and by having a series of vats, with communicating tubes or siphons, a charge of bark can be transferred from one to another until it is exhausted to such an extent that the small remaining percentage of a tannic acid can only be removed by hot water. The vats are constructed so as to expose a maximum of evaporating surface to the atmosphere, and if the evaporation can be carried on wholly or in part by means of the heat of the sun, so much the better, firstly, because the consumption of fuel will be minimised, and secondly, because the process should be conducted at as low a temperature as convenient.

The preparation of wattle bark extract has been attempted in all of the colonies, but in only one has it passed the experimental stage, so far as I know. The process is analogous to "concentration" in metallurgical operations, for the tannic acid in bulky, unsaleable material can be highly concentrated, and barks weak in tannic acid can be utilized for the same reason. The industry of extract-making is tempting, and I am confident that there is much money in it for some of our country district whose circumstances are favourable. I trust, therefore, that it will soon be the means of affording profitable occupation to many people.

The dark colour of extracts is an objection, and many experiments have been undertaken with the view to minimise the evil, with no very satisfactory results up to the present. Nothing is easier than to decolorise extract, but the difficulty is not to destroy the tannic acid at the same time.

The following notes relating to the making of extract of hemlock bark are taken from Proctor's "Text-book of Tanning," and may be suggestive:—"The bark, in pieces $\frac{1}{2}$ -1 in. thick and several inches long, is soaked for about fifteen minutes in water at 200 deg. F. (93 deg. C.); it is then fed into a hopper, which conducts it to a 3-roller machine, something like a sugar-cane mill, through which it passes, coming out lacerated and compressed; it next falls into a vat of hot water, where it is agitated by a wheel that the tannin from the crushed cells may be dissolved in the water; hence it is raised by a series of buckets on an endless chain, somewhat in the manner of a grain elevator to another hopper, whence it is fed to another 3-roller mill; here it receives its final compression, and comes out in flakes or sheets, like coarse paper, and almost free from tannin. The buckets are made of coare wire that the water may drip through during elevation. In order to avoid the blackening action of iron, whenever this metal will come into contact with the solutions it is thickly coated with zinc. The solution is evaporated to a solid consistency, generally by vacuum-pans. About 2 tons of bark are represented

by 1 barrel (of less than 500 lb.) of extract." And, again,—“It is one of the great attractions of extracts that they avoid almost all the expense and labour inseparable from the exhaustion of other tanning materials. It is usually necessary to dissolve the fluid extracts in water or liquor of as high a temperature as has been employed in their preparation, as otherwise, from some unexplained chemical change, a large portion of the tannin is precipitated, probably as an anhydride of tannin.” It is of very little use, however, looking to the local demand for tanning material to take off more than a limited quantity of the *Acacia decurrens* bark or extract. It is the market in Europe that must be considered and last month's London quotations for "Australian chopped bark" (catalogued as *Mimosa*) was from £6 to £10 10s. per ton. We suppose this holds good as well for "*A. decurrens*" bark, but we are unable to say how the extract sells, although, judging by the Australian trade, it must be satisfactory. Unfortunately, Mr. Maiden's pamphlet was issued in 1891 and the statistics are only up to 1889. In that year, 21,625 tons of bark were exported from all the Colonies, the value being entered at about £200,000. Now, in reference to Mr. Kellow's proposal that a Company should be formed to take up land—a free grant (?) from Government for a new industry—between Nannoya and Ambawela, we must remember that the timber (as well as the bark) should be utilized, at least as firewood now in so much demand for tea factories in Dimbula. The return from firewood, perhaps, could not be put down at much; but Mr. Maiden's Estimate of Receipts from a wattle Plantation of 100 acres (400 trees to the acre) for bark alone aggregates £4,852 for 1,215 tons of bark gathered between the 5th and 8th years inclusive; while the total expenditure is given at £2,215, leaving a profit of £2,637. It may be said that these figures are not applicable to Ceylon, but it is very probable that with our cheaper labour and free land (if a grant were obtained) the outlay here would be less. At any rate, for the present we may leave these "facts and figures" for the consideration of any in our midst who are on the lookout for a new industry to be promoted by a Limited Company or by individuals.

It is rather interesting to note that of the three new industries now pressed on the attention of our Planting and Agricultural community, that in "Wattles and Wattle Bark" should be the only one suited for a high elevation. The cultivation of "Rhea" and, indeed, that of "Para Rubber" are more particularly adapted for the lowcountry or the lower valleys in our hill-country. We are, of course, aware that a good deal of Rubber has already been planted one way or another, and, no doubt, there are fields of Rhea in certain directions of which not much is said. It now remains that a fair trial should be given to "Wattles and Wattle Barks" in the direction recommended by Mr. Kellow under the guidance afforded in his valuable pamphlet by the scientific expert, Mr. Maiden of New South Wales.

AGRICULTURE AND SCIENCE.

Following on Mr. Green's appointment we may take the following announcement (appearing in the *Government Gazette*) to be a further step towards the goal of a fully constituted Agricultural-Scientific Board to work in the direct interests of the European and Native planters and cultivators of all

degrees in the island. Mr. Willis's detailed proposals have generally our approval, only he must recognise the fact that any letter or circular affecting the leading industries of the island will at once be, in his time as in that of his predecessors, published and discussed in the daily press and so secure a far wider circulation (among readers of English) than he or the Government could give to it among the educated community. Again, correspondence arising out of any bulletin will necessarily gravitate to the press, rather than to Mr. Willis—and the latter must remember that the planters include men of great experience and shrewdness, as well as practical agriculturists. Now, how are the "commentaries" as well as the "text" to be preserved and made available for ready reference? Mr. Willis can scarcely turn the *Gazette* into an Agricultural journal for correspondents as well as for his bulletins? It was to supply this felt want that we (personally) so long ago as 1881 started *The Tropical Agriculturist*, in which not only everything locally published, but all we can gather from other lands, bearing upon our subject, is embodied. Dr. Trimen most fully approved of and constantly contributed to the *T.A.*; while he seemed to have the index of the successive volumes (there are 16 volumes with the one closing this month and all handy of reference) at his fingers' ends, often writing to us, "I see you are discussing — — — you will find all about that product in *T.A.* vol.—page—and vol.—page—" and so on. Mr. Willis's bulletins will be specially useful for reference in the monthly *T.A.* But let him beware of starting experiments or discussions which have already been thrashed out in Ceylon. Beware too, of trying too much at first—essay lectures for instance; although practical demonstrations at the Gardens ought to be widely beneficial; as also the proposed tours, and inquiries as to new products, local pests, &c., which indeed might be made most useful. We are ready to help in every way in our power and think a very interesting "departure" is indicated in Mr. Willis's programme:—

COMMUNICATION AND CO-OPERATION BETWEEN THE DEPARTMENT OF THE ROYAL BOTANIC GARDENS AND THE AGRICULTURISTS, &c., OF THE COLONY.

It is very desirable that there should be greater and more ready communication and co-operation between the Department of the Royal Botanic Gardens and those whom it is chiefly designed to benefit, viz., the agriculturists, horticulturists, and botanists of the Colony. Many interesting cultivations, experiments, &c., are often going on in the Gardens, of which the public sees or hears nothing except in the brief annual report, which is not the place in which to give detailed accounts of such work. And, on the other hand, the staff of the Department, for want of better communication and means of getting information, often remain for long in ignorance of important occurrences, such as the appearance of new diseases, the starting of new cultivations or new methods of cultivation, and so on. A few suggestions as to ways of overcoming these difficulties are given below:—

I.—PUBLICATION OF INFORMATION CONCERNING THE GARDENS AND WHAT IS GOING ON THEREIN.

(1) I would suggest the publication at intervals of a series of circulars or bulletins, each as a rule dealing with one subject only. The cost of a one-page circular would be about K3 per 1,000 copies. These circulars might be kept at the Gardens and distributed free or sent by post or receipt of a stamp for postage. Their publication should not be at fixed intervals, but whenever required. As examples of

what is meant, the first few might deal with "the Chocho," "Rhea fibre," "the Cacao disease," "new ornamental plants," and so on. In some cases Sinhalese or Tamil translations might also be prepared for distribution among the villagers.

(2) I would suggest the publication in the *Government Gazette* and elsewhere, if thought desirable, of advertisements of important seeds or plants on sale at the Gardens.

(3) I would also suggest the giving of occasional lectures on important subjects, such as diseases of plants, new cultivations, &c., by the staff of the Department in Colombo, Kandy, or elsewhere. Also the giving of occasional demonstrations at the Gardens upon such subjects, e.g., upon rubber-tapping at Henaratgoda, or upon fibre plants at Peradeniya. Notice of such meetings in Kandy. Such lectures or demonstrations could hardly fail to be of mutual advantage both to cultivators and to this Department.

II.—THE COLLECTION OF INFORMATION BY AND FOR THE DEPARTMENT.

(4) I would suggest that occasional tours be made in different districts of the Colony to investigate the various cultivations carried on, the diseases of plants, &c.; and that the results of these investigations be from time to time submitted to Government as special reports, which might also, when deemed advisable, be published as separate bulletins or circulars (see above).

(5) I would suggest that the Superintendent of Hakgala Garden and the Curator of Peradeniya Garden should be authorized to travel with or in place of the Director on these expeditions whenever the aid or advice of a highly skilled practical Gardener is needed.

(6) I would suggest that the Government Agents and other Administrative Officers, native headmen, Secretaries of planters' Associations, &c., be requested to assist this Department by informing me from time to time of new cultivations started, old ones abandoned, outbreaks of diseases, and so on. Such a request might well form part of the first (introductory) circular issued by this Department.

JOHN C. WILLIS,
Director, Royal Botanic Gardens

THE CACAO DISEASE AGAIN.

Mr. J. R. Martin affords us a very straightforward account of his connection with the steps taken to provide for the scientific investigation of the cacao disease. It shows that so far from being opposed to such inquiry, he has specially courted it—only that he dreaded exaggerated reports of the extent of the evil so soon as it was known the Government had been moved to take the matter in hand. We can sympathise to some extent with this feeling; but the great matter to be regretted now is that Messrs. Martin and Dickenson did not know how exactly Mr. E. E. Green, was, as an entomologist, fitted to undertake for them the investigation inquired. We take it Mr. Martin has not seen Mr. Green's scientific work or he would have felt safe in inviting him to examine any trouble or disease attributable to a "poochie." Had it been a fungus, the case would have been different. But, as matters stand, we trust the Government will lose no time in asking their "honorary entomologist" to visit, examine and report on the cacao disease, induced by a "poochie," in the Matale, Dumbara and Kurunegala districts. Even if Mr. Green were unable to provide an adequate remedy, his report could not fail to supply the information required at Kew or by referee experts in the mother country.

THE TRINIDAD BOTANIC GARDENS.

We have before us the Report for last year on the Royal Botanic Gardens of Trinidad by their accomplished Superintendent Mr. J. H. Hart; and it may be useful to touch on some of its main features, in connection with the Administration Report on our own Botanic Gardens from the pen of the new Director, which we recently noticed. The interesting West Indian Island is, of course, a much smaller charge than Ceylon, covering as it does only over 2,000 square miles against our 24,000; but the meteorological conditions, so far as mean temperature goes, are much alike—the island being situated between 10 and 11 degrees North Latitude and 61 and 62 West Longitude, against 5 and 10 degrees in our own case, and 80 and 82 East Longitude. There, January is described as the coolest month, February the driest, May the hottest (as has been our experience this year), June the wettest, and August the moistest. Its rainfall, however, does not show the great divergence which is seen in Ceylon with Padupola claiming nearly 230 inches, while Maruchikadu has to be content with less than 23; for we find that the highest fall for the year was in Saugre Grande which had 154 inches, and the lowest Moruga Police Station with less than 40 inches. The average for the whole island is 81.52.

We learn that the work of the Herbarium has made steady progress during the year, the collection of specimens of the Island Flora being made gradually more complete; while the whole of the indigenous plants have now been separated from those which are known to have been introduced from other countries. The very interesting re-discovery is chronicled of the *Sacoglottis amazonica*, as a result of a special expedition into the Trois district; and the importance of it is enhanced in that it has definitely decided the source of one of the drift fruits" discussed in the reports of the "Challenger Expedition." Another "find" illustrates the difficulties attendant on accurate botanical research. For years Botanists have desired definite information in regard to the tree locally known as the "Coutrevent," and nine years have elapsed since Mr. Hart's Department commenced the investigation; but the distance to the habitat of the trees, the short period of flowering, and the height of the great forest trees, opposed such difficulties in the way of obtaining good specimens that the result has been only one fairly good single sheet of Botanical specimens. By the aid of this sheet, however, the Director of the Royal Gardens at Kew has been able to determine, that the locally well-known tree is an undescribed species of the order *Sapotaceæ*, and not a *Lucuma multiflora*. Under the same heading we find a paragraph on the destructiveness of fungi, even where hard-woods are concerned, which we reproduce for the information and guidance of agriculturists and builders alike:—

Polystictes sanguines, L., a finely coloured fungus, was found destroying hardwood gate-posts in one of the pastures; posts that had only been in the ground a few months being entirely destroyed. From this and other observed instances it appears evident that the knowledge of the destructive nature both of Saprophytic as well as Parasitic fungi, has not as yet been put to such practical use as it might be. Perhaps the fact that people who have not had them under close observation and study can hardly realize that such apparently (to them) insignificant organisms should do so much harm. We constantly see builders, carpenters &c., laboriously tarring or painting and even charring the ends of posts, the sills of houses, and the flooring of bridges, &c., &c., when the work

is often absolutely worse than useless; for the germs of decay in the form of the mycelium of a fungus have already permeated the woody tissue, so that all they do in many cases is to seal up in the interior of the wood, and in a suitable place for its growth, the vegetative and most destructive part of a Saprophytic fungus. The indications of the action of these minute vegetable organisms is much more pronounced in a tropical, than in a temperate climate; the destructive action is much quicker, there is far better opportunity for observation, and the damage is more quickly apparent. Modern Science shows, however, that the only means of properly treating or preserving timber is first to sterilize it by heat, to thoroughly dry it, and afterwards to use outside preservatives in the form of paint, tar, or charred surfaces, &c., &c., Creosote is often used to preserve timber, but unless the operation is performed exceptionally well, "Creosoted" timber fall a prey to "dry rot," otherwise fungus, almost as readily as any other, especially in the Tropics. Applications of preservatives should always be made under pressure, and with sufficient heat to destroy the growing parts of these destructive fungi.

Among the work undertaken by the Department was the revision of a pamphlet intended for the guidance of emigrants from the United Kingdom; and it is hoped that the correct information supplied will have the effect of attracting capitalists seeking investment in the Tropics. Government House being situated within the bounds of the Gardens, the Department has not disdanced attention to flowers, and has even engaged in decorative work by furnishing plants for ball-rooms and places of public and private entertainment. We are in advance of that here; but we are not sure that the number and enterprise of Florists and Nurserymen in our midst, adequate as they are to render the intervention of the Botanical Department unnecessary for decorative work, are sufficient to relieve the Botanical Gardens of the task of cultivating flower and foliage plants for sale to visitors. We know that successive Directors have expressed impatience with this branch of their charge; but does it not serve a purpose in rendering the Botanic Gardens bright and attractive, and especially in training Gardeners for better work—apart from the help it gives in propagating specimens not easily obtained elsewhere, and not so readily within reach of all classes? The Trinidad Gardens, while helpful to local plant fanciers, have not been neglectful of foreign exchange and distribution, as the statistical tables show. The Department keeps in its hands the issue of a quarterly Bulletin of about 25 pages, neatly and attractively got up, which must be of help and interest to the planting and agricultural as to the general public. Here the *Tropical Agriculturist*, and to some extent the daily Press, have hitherto obviated the necessity for such a compilation, pending the publication of the Annual Reports. From the notes on the Economic Section, we learn that an experimental plot has been established in the Gardens for raising and testing seedling canes—sugar being the main staple of the island. The culture of 41 varieties was commenced during the year, and 86 examinations were made to test the quality of the canes, in regard to the constituents which give them value. One of the facts ascertained by experiment is that the canes did not reach their maximum yield until nearly the end of the crop season which, curiously is in May, or even after, whereas in British Guiana which is not far off the season closes as early as December! During the year as many as 7971 seedling canes of the best of the new varieties were distri-

bated. On this point, as illustrating how much Botanic Gardens can do to help agricultural enterprise, as has been early and earnestly recognised by our own Director, we quote as follows:—

Although I am unable to report on the value of the canes grown during 1896 at the Gardens, still I am able, through the kindness of Messrs. Jenman and Harrison, to mention that their best seedlings have again for the fifth time maintained their pre-eminence over the older kinds, in yield per acre and in richness of juice, so that planters in Trinidad may have the satisfaction of knowing that the canes distributed to them have been through long and carefully conducted tests, both agriculturally and chemically, for a series of years; which should be a reliable guarantee of their character. I do not think, however, that any cane should be recommended to the planter as being of the highest class until it has been widely and largely cultivated in the field, and no one has been more careful in this than the Demerara growers. It is certainly the duty of the seedling growers to advise the very careful extension of the area under cultivation in new varieties, and therefore the extension of that area is a matter that must rest with the planter alone. While refraining, however from recommending any particular cane, the planter's attention should be called to record of the yield of the several varieties on the trial fields, for, by knowing the character of these fields and the cultivation given, they should be able to select from the assortment offered that cane which will be most suitable to their purpose, or best suited to the character of the land which they may have under cultivation. We have an example in the Burke Cane which is highly instructive. This cane, it appears, is one which, seen upon the field, is certainly one to make glad the heart of the planter, but when it comes to the factory it is found to yield a juice which is not equal to that obtained from the older varieties. The megass also—now used for fuel in all modern factories—is deficient in heating power, when compared with that of the older kinds. Notwithstanding these facts, there is not a little to be said in its favour. The cane has certainly a very vigorous constitution, and is but little subject to disease in comparison with some others, and it may moreover become especially useful as a parent plant for future seedlings, by giving a strong vitality to its progeny.

Then follow remarks on pineapple seedlings, cacao (containing much of interest to local growers, part of which was reproduced in our Director's Report), varieties of coffee (which is attracting the attention of planters in view of the fall in price of cacao), citron, oranges and other products, which we cannot do more than mention here; but we are sure to reproduce most of the interesting paragraphs at length in our monthly periodical. A special interest attaches to the Report under notice, as it marks the completion of a century of British rule in Trinidad, and the eightieth year of the existence of the Gardens on their present site—the oldest West Indian Botanic Gardens. Long may they flourish!

THE DISEASE AFFECTING CACAO TREES.

in different districts is thus considered by a correspondent who has not, so far as we know, hitherto taken part in the discussion:—

The cocoa disease is most certainly not a root disease; there, Mr. Martin is right—but the Poochie is well known, and described in Mr. Vander Poorten's letter to you some time back.

Mr. Martin says:—It certainly is not a root disease as the tendency is to work upwards from a puncture, but if allowed to develop the sap becomes vitiated and the roots therefore become unhealthy. Here Mr. Martin is wrong, if the insect attacks the tree anywhere above the collar there is a strong chance of a healthy sucker growing and, forming a fine tree. I have seen dozens such now years old and believe them to be healthy today.

A superintendent of a large estate in Dumbura was heard to say, hardly one tree originally planted now remains, but have been replaced; on another not in Dumbura, figures were given me showing 33% cut out in 18 months. Can this be the place Mr. Martin refers to—where does profit come in. I went through an estate a few days ago where in spite of trees being periodically destroyed, the disease increases—why? *the Poochie's attack is only discovered when the damage is done*, when one discovers the bleeding (described by Mr. Martin) the only sure way is to cut the tree down and burn the part cut away.

I have treated and seen treated hundreds of attacked trees with but poor results and have seen fields where supplies of the hardy kinds have refused to grow and on others they have come on well—the work done by the same man, A. V. De P.

I told a cocoa planter 18 months ago of this pest, he did not know of it then, but was confident he could overcome it should it attack his property it has done so and now he makes people believe; he has no trouble for it only takes a certain time to replace the tree.

I saw the disease on an estate when it first showed up there and counted 40 trees in a patch, I said they were doomed and they died; this place which had been a good one became the talk of the district and from being as dense as a forest, one could look all over the place. These are facts. I can give you names and places for all I state and are these in themselves not enough (as you say) to show that an Entomologist ought to have been at work long ago. It is right down foolish to say we in this or that district, have not much to complain of thus throwing cold water on a pressing need; let them wait and in a very short time their turns may come. Dumbura first, Kurunegala second, Wattagama third, why not Matale fourth. You are, right, no time should be lost—in fact too much has been lost. My idea is still that people holding cocoa property wish to hush up the fact that it is in a bad way from various causes, but particularly the poochie in question.

THE AGRICULTURAL SCIENTIFIC BOARD.

A shrewd, but somewhat cynical, planting authority speaks out as follows:—

"The Government has at last had its eyes opened to the need of scientific men being employed to investigate pests affecting the agriculture of the country. The attitude of the late Chairman of the Planters' Association, the then Planting Member of Council and of Mr. T. North Christie when Messrs. Gibbon and Cross agitated for a Scientist, put back the clock; but Mr. T. North Christie, like the wise man he is, saw his error and did his best in advising the present Governor to hurry up the appointment of an investigator. However, planters, native and European, will have to be on the alert, lest the present flash in the pan dies out with the honorary appointment of Mr. Green. Why don't we have Honorary Colonial Secretaries, &c.? Government will spend money on beautifying Nuwara Eliya or any place where it is pleasant to pass the hot season; but spending money on scientific departments will not catch on long. If some of the money spent on the tomfoolery Sir Arthur Gordon indulged in, when he multiplied Government Agencies and so multiplied Provincial offices and cost of buildings to represent worthily the splendour of those new Provincial Chiefs, had been devoted to providing a decent salary for a proper Railway Manager, or salaries of scientific men to report on our Agriculture, &c. What a blessing to Ceylon that would have been?

"Peg away, therefore, till we have two Scientific Investigators to watch over the Agriculture of the Colony, and have nothing to do with Honorary Appointments."

MR. CROLE'S BOOK ON TEA.

TEA.—A Text Book of Tea Planting and Manufacture; comprising chapters on the history and development of the industry, the cultivation of the tea plant, the preparation of the leaf for the market, the botany and chemistry of tea, &c., &c., with some account of the laws affecting labour in tea gardens in Assam and elsewhere, by David Crole, late of the Jokai Tea Company, &c. (Crosby, Lockwood and Son, London.)

This is a substantial and attractively got up volume. Though not fully illustrated in accordance with modern ideas in all the departments of cultivation and manufacture, it contains many graphic full-plate illustrations of forest jungle clearing, elephants loading timber, and entirely novel and capital views of tea in Natal supplied by the Colonial Office, which alone are a great acquisition. In addition to this the end of each chapter is embellished with an effective "tailpiece," illustrative of tea gardens, Chinese and other antiquated methods. A map showing the tea districts of India and Ceylon is also given with many plans of buildings diagrams and numerous tables of statistics analyses of teas and soils. In the preface we learn that the author has had varied and important experience on plantations in Assam, and that he also spent the best part of two seasons touring amongst gardens in India and Ceylon, all giving exceptional advantages for the preparation of such a work. The book deals with the subject historically, practically, scientifically, and statistically. No such comprehensive effort in the literature of tea has hitherto been made.

There can be no doubt that Mr. Crole renders good service to the cause of tea in much that he recommends. He strongly and repeatedly urges the introduction of labour-saving appliances, especially in outdoor operations, such as the preparation of clearances prior to planting, draining, &c.; well-arranged buildings of sufficient capacity and fully equipped with machinery to cope with the greatest possible rush of leaf, pointing out how every manager who wishes to earn and enjoy success must take advantage of every detail whereby labour and time can be saved; the partitioning off of the artificial withering house into apartments to be worked independently, and so on. In the view of recent and present enormous extensions and probable over-production, he reiterates as a necessity, the pushing for an extension of foreign markets with the utmost energy, and warns planters that it would be wise if they would expend some of their profits in opening out new and extending markets rather than in bringing still more tea under cultivation. Mr. Crole very commendably contributes to the condemnation of our London warehouse abuses. He also dwells upon the important matter of preventing damage from fires by means of hand engines, hose, buckets, and asbestos painting. This cannot be too forcibly or too frequently brought home to all concerned. We know of factories with an ample supply of water, fitted with hose, and with pressure to eject the water over the roof. Yet the most careful are the most grateful for the reminder that the apparatus should be kept in perfect working order, the hose always attached and the buckets ready, and within easy reach for any emergency, to obviate delay in case of darkness or excitement. Knowing the risks incurred on tea gardens in too many instances, the wonder is not that premiums of insurance are what they are, but that they are not really much higher. And we cordially endorse Mr. Crole's suggestion that owing to the fall in exchange—the more so as proprietors gain so much by it—in all cases where the remuneration of European employes is in rupees, and upon the former scale, it should in fairness be readjusted.

Readers will find much besides that is at least suggestive on such subjects as the use of tramways, trolleys, and turn-tables in the factory and upon the garden, drainage, diagonal and triangular planting, plucking machines, the use of dynamite in clearances,

the refrigerator in fermentation, an improved method of dealing with frontier tribes by the taking of hostages, hybridising, grafting and enarching to improve and invigorate the tea stock, and much else touched upon. It must, however, be admitted that the last-named suggestion fails to bring much consolation to those interested in the 912,500 acres of British grown tea Mr. Crole estimates to be already under plant.

The author informs us that his hardest task was over the historical section. He has evidently drawn from all sources and does good work in the compilation of this, but it is open to doubt if very much has actually been gained to the tea historian in the way of accuracy or completeness. Mr. Crole, after dwelling at considerable length on the subject, and going into detail as to the proof of it, arrives at the generally accepted conclusion that that there was originally but one species of tea, the Indian, and from that country it found its way to China, the stunted proportions and diminished proportions of the China variety being the result of unfavourable conditions of soil, climate, and treatment for centuries.

The treatment of the "Chemistry of Tea" seems too much a lecture on organic chemistry and text-book work without much special reference to tea. We are not shown the result of investigations. For instance, we are told, what has often been heard before, that light is objectionable in certain processes, but no proof is given of this. There are no comparative tables of analyses (none of Darjeeling tea at all) showing the different constituents of "quality" and "inferior" teas, or the results of good and bad methods, or the changes that actually occur in the different stages and processes. Notwithstanding the sweeping denunciation of the "meat tea," the evil effects are only *in posse*, but do not follow in fact. Were Mr. Crole practically right, there should be no meat or eggs to breakfast, and little tea-drinking. We doubt if much light has been thrown upon science in tea, but, all the same, Mr. Crole has rendered a great service in writing upon a subject too little studied or thought about, which cannot fail to lead to discussion and further study and investigation, to the advantage of the tea industry.

Like the historical portion, the statistical is very comprehensive, and drawn from all sources. Upon this head, we would merely remark that, under the apprehension of over-production, it is some consolation to have good reason to believe that the area under tea, for 1897 even, is considerably over estimated at 519,500 acres. In regard to Ceylon, put at 400,000 acres, we have returns till the close of 1895 (a year later than have yet come to hand for India), and we know that the best Ceylon authorities do not estimate their area as more than 340,000 acres at the close of 1896, or say, more than 365,000 acres for 1897 at the outside. For India the latest official returns we have seen are till end of 1894, by which the total area was brought out at 423,006 acres. The increase throughout India is difficult to estimate; but with the exception of Travancore and Cochin (probably under-stated) we are sure it has been over-estimated, and in the case of one of the leading districts the area is certainly put down at 30 per cent more than it is at present. Though interesting to know, it is impossible without reliable local knowledge to state even approximately the extent under tea in the Straits Settlements, Fiji, &c. But if this has been over-stated the total result is not seriously affected. From the Government Blue Books these areas would seem to have diminished rather than increased in recent years. We should not be disposed to put the area of British-grown tea at over 780,000 acres at the close of 1895, or 850,000 acres at the present time.

As regards the practical in tea, we must as far as possible pass over controverted points.

Mr. Crole is untiring in his condemnation of the so-called China plant, and speaks of it as "a curse that at one time seemed as it would prove as disastrous to Assam as ever the *Phylloera vitatrix* has been in

France, or the *Hemilea vastatrix* in Ceylon." The fact is that while no one will deny that the Assam plant, or at any rate a hybrid suitable for the locality, is preferable, the most has not been made of the too much despised China bush.* It has never had a really fair chance in Assam. The failures prior to, and the crisis of 1866, brought a reaction against the China plant, and other practices sound in principle, such as the distance apart plants should be put out, and led to serious mistakes in opposite directions. It would seem that the hybrids at all allied to the China plant are held but in little better repute by Mr. Crole. While he claims that the produce of the indigenous plant brings 10 per cent. to 20 per cent. per lb. more than that of the China in the London market, he seems to overlook the fact that the indigenous quality very rarely has brought the best prices, except in the olden times when Indian tea was used, and in small proportions, for blending, and what has long been the highest-priced tea in the world is the produce of a mild hybrid or of a blended variety of plants upon Darjeeling gardens, where the China kind predominates. Of course, apart from *jât* of plant, quality is greatly a question of soil, as exemplified in Assam as well as the Darjeeling district. We doubt whether Mr. Crole has ever gone to the root of the vital questions affecting the thorough preparation of land prior to planting and enlightened cultivation afterwards. His remarks seem not to go beyond what will admit of the methodical and perfect lining out of a garden. Depend upon it, this is a more-vital matter. Success in the long run, failure, or recovery from failure, will ultimately be found to depend more upon the field than even the factory, most important though the latter be. Certainly the book displays no acquaintance with hill cultivation and its be-setting difficulties. As to buildings, his plans seem rather those of some existing factory than of what would be perfection. All are upon a gigantic scale, no doubt, and suggestive of grand ideas, but certainly not always with an adequate regard for arrangement or economy of space. We question if houses for the natural withering of leaf, so wide as specified, would act at all satisfactorily, even in the climate of Assam. Nor would a common chimney stalk, for boilers with underground flues from driers connecting work satisfactorily, unless situated upon a mound or knoll; and there are insurmountable drawbacks to underground pits for main shafting which with economy of space and outlay can be placed overhead, where it can infinitely more easily be seen to and kept in good condition. In machinery many obsolete machines ("Lyle's" is styled "*Lyall's*") and others of which experience could only have been had in the patentee's yards—where they cannot be thoroughly tested—are confidently recommended. And how can it be seriously asserted, in this year of grace, by any practical man, that the rude bag machines could ever roll "fine leaf" better than a modern machine such as the "Rapid," which is as near as can be imagined perfection? Most will admit that there was a waste of labour where two able-bodied men or more were placed in charge of one roller, as was not unknown in old times when a single machine had to get through three times the work one is put to in these days, yet all must pity the one boy who is put to attend to "six machines in full swing"! It seems also difficult for the lay mind to understand from "acquaintance with the weather," or "the feel of the leaf on the changes," whether the leaf is liable to get heated or not in the machine irrespective of speed, pressure, or closeness. And strange that the time required for fermentation is to be determined by the difference between one garden and another, and in no measure to the season of the year, temperature of the day or whether. The great subject of manuring, sufficient alone for a volume, is but casually

alluded to in the chapters upon the "Botany of Tea" and "The Coolie"; and the practical application of *Leguminosæ* to tea is dismissed with such few words as might indicate that after the MS. had been completed a line or two alluding to this subject (and what the author terms "green soiling") have been interpolated on noticing attention recently directed to it in various quarters. On blights the work is conspicuously defective as to practical suggestions. The author from his remarks does not seem aware that the old-fashioned cure of sulphur applied upon a simple and expensive method, has long ago been proved an effectual remedy for red spider, and at the same time a valuable manner in many instances. The only light shed upon this much vexed question is that Mr. Crole has discovered two new species of faggot worm which he adds to the legion of parasites he gives as preying upon tea.

Many other similar topics, most of which may seem of minor importance, might be alluded to.

There is often a mingling of the old obsolete objectionable methods with the approved and the ideal which we fear may have a tendency to mislead the uninitiated. For instance, when seriously told of tea seed having been sown broadcast from the backs of elephants, who were "made to peregrinate in a more or less aimless manner about the land it was desired to bring under tea," which could never be more than a piece of pure romance, it is going too far. And we cannot refrain from protesting against the injustice done the industry in representing that it is the sick, and those suffering from sores and accompanied by babies that are employed to handle the tea in sorting in the final stages, while the fact is that no such thing has been tolerated in any well-regulated factory during the last fifteen years.

In the interests of the tea industry we feel bound to notice a few recommendations which are fraught with danger. The best distance for planting a garden is said to be 4ft. by 4ft. 16ft. (= or even = 15.85 superficial feet of space per plant if planting triangularly as recommended). This is opposed to all sound principles of planting. On the contrary, for fully developing the capabilities of a garden, in the long run, for Assam we should say twice this space, at least 6ft. by 5ft. (and for the hills say 5ft by 4ft. on the base) should be allowed; and with a view to cultivating by machinery, as advocated by Mr. Crole, even lines wider apart would be an advantage. Mr. Crole remarks that hosing should always leave the soil rough. Clod cultivation—or as in some cases as practised it might even be styled slab cultivation—is a great fallacy in tropical culture, especially when lengthened periods of dry weather may be expected. Pruning by measure is reprehensible (as well as antiquated, surely), and if not in some instances the leaving of heavily-cut bushes unpruned next year, certainly the "slashing them across the top"; worse still to burn down roof and branch as a remedy for musquito blight, a cure certainly infinitely worse than the disease. The eliminating of all *bani* leaf, as advocated, not only unduly weakens all except the most robust bushes, but deteriorates the quality of the after flushes. In those days where quality above all should be aimed at, it is objectionable and entirely unnecessary to handle all the tea, or any but the coarser, in sorting; and we cannot agree with the author (though the majority may yet do so) that tea deteriorates (but the very reverse) in properly constructed "bins." Neither ought chests to be packed to contain so much as 150 lb. of tea, but we would rather name 95 lb., or at most 100 lb., as the net limit. We are confident that tea ought to be bulked at the factory, not only because there it can be best done—considering the present methods and appliances at the London warehouse—but to curtail the warehouse charges as exemplified in the profits of 45 per cent and 80 per cent consecutive dividends from one warehouse company shown in some tea company's printed accounts.

Mr. Crole alludes to a question recently raised by a "silly letter" in a religious journal; and states it to be his opinion that troubles between the planter and his coolies are invariably due to want of tact

* Quite true: there is a field of pure "China" in Ceylon yielding a full crop of very fine tea, but this is at a high elevation—and although a "hybrid" may be, generally, more profitable, much can be done with "China" at high elevations both in India and Ceylon.
—ED. T.A.

on his part; that employers with married assistants, and even managers, are placed at a disadvantage; and that the directors of companies would scarcely be acting within their province if they constituted themselves the censors or guardians of their employé's morals.

We have only indicated some of the subjects, all of which had many more Mr. Crole deals with in detail. Though it has been far from our wish to criticise more than is imperative, and we have done so on all material points, we are well aware that we have not done justice to many excellencies. Our desire is that all study the volumes for themselves. It has often been forced upon us that, with very few exceptions, practical planters belong to either of two classes—(1) Those who do not feel equal to writing at all, or will not take the trouble to give the public the benefit of their experience; (2) those who believe they know everything, but for this very reason do not see the force of divulging their secrets to make others as wise as themselves. We can to a certain extent sympathise with both classes. Owing to the occasional vagueness of expression in one so gifted with a facile pen, we have not been enabled entirely to divest ourself of the suspicion that Mr. Crole naturally reserves a good deal for his opportunities when consulted professionally. As so few will write about tea, we do not forget that those interested in the industry are placed under all the greater obligation to the author for the attention he has devoted to, and the interest infused into all branches of his subject.

In conclusion, we congratulate Mr. Crole upon the successful issue of his labours, as a whole, and again most cordially recommend his book to the general planting public, trusting it may find its way into many hands.—*H. and C. Mail*, May 21.

JAPAN TEA.

The delicate flavour and aroma which the Japanese tea-drinkers make so much of in the so-called "new tea" will not probably strike foreigners as anything specially palatable. As soon as the new leaf is on the market, all tea shops display a notice with two Chinese ideographs representing "New Tea," written in conspicuous style. The labour and care involved in raising and preparing tea are really beyond the appreciation of outsiders, to whom the leaves come packed in boxes carefully sealed and labelled and ready for use. The quality of tea depends not only upon the nature of the leaf itself but also upon the time of picking. For instance, leaves picked at night-time, wet with dew, will make tea of superior quality, while those plucked in the day time make an ordinary tea. From the end of April, the famous tea plantation of Uji near Kyoto, presents an interesting and busy scene as the picking season sets in. This place enjoys an unrivalled reputation in this country as producing tea of the best quality, the nature of the soil and the climatic conditions there being specially adapted for its cultivation. A village in Uji, called Ikeno-o, claims the unique honour of producing tea for the consumption of the Imperial Family. It is said that the nature of the soil is not the sole consideration for the production of tea of superior quality. When the new leaves began to sprout, tea growers plant posts in four corners of the garden, and at the height of about eighteen feet they stretch bamboo poles, over which they lay a straw covering specially provided for the purpose. This is done partly to protect the shrubs from being frost-bitten and partly from a curious idea that drops of rain dripping through the straw impart some additional flavour to the tea-leaves. Hence the name "Gioku-ro" (Pearly Dew), given to the leaf of the best quality in this country.—*Japan Times*, May 14.

According to the *Osaka Mainichi*, the prospects of the tea crop in the vicinity of Kyoto (the favourite Uji tea) are good. The gathering of the tea for export to America is already finished and the leaf is now in process of manufacture. The picking tea for home

consumption was to commence on the 10th inst. The crop was bad last year owing to damage caused by frost and worms, but the case is very different this year, the prospect being bright in every respect. The budding was delayed a week this year, but it seems that this does not affect the success of the crop. As the crop failed last year, old stocks in the market are small, and consequently there will be an increase of 10 *yen* per 100 *kin* in the quotations compared with the corresponding period of last year.

A deputation from the Japan Tea Guilds, consisting of Messrs. K. Ito (Kyoto), S. Mihashi (Shizuoka), S. Miyama (Miye), and S. Saka (Tokyo), has had an interview with Mr. Oishi, Vice-Minister of Agriculture and Commerce, on the subject of the new tariff proposed in the United States. They point out that the price of tea in Japan is 20 *yen* per 100 *kin*, and a duty of 10 cents per pound will just double the price; to this must be added freight, insurance, commission, and other charges, which will bring the selling price in the American market up to 65 *yen* per 100 *kin*. This, they imagine, will put an end to the sale of Japanese tea in America; but they overlook the fact that the Americans must have tea, whatever the price may be, and prices of all teas alike will go up, whether from Japan, China, or India, so that the increase of duty really concerns Japan very little indeed.—*Japan Times*, May 15.

The Yokohama Tea Traders' Association issued the following instructions to the tea-producers in Gifu Ken on the 15th instant:—(1.) That it is necessary, as the result of the American Regulations prohibiting the importation of tea that all tea should be of superior quality. (2.) That the manufacture of green tea should be abandoned if possible, but if not, to improve the quality of that kind. (3.) That any leaf that is in any degree rotten should not be used.

We learn from the *Yomiuri* that the following advice to the Yokohama Tea-dealers guild was issued by the Municipal Office, on the 14th inst:—The law prohibiting the importation of bad tea to America, lately passed, might prove advantageous to the Japanese tea-dealer, in the sense that it warns against the export of bad tea and consequently would tend to raise the demand for genuine Japanese tea among the Americans. If, on the contrary, there should be shipped even one chest of tea against the law, the result is not only the loss of that particular chest, but obstacles will be thrown in the way of Japanese exports in general. It is, therefore, absolutely necessary now the tea season is on, that tea-dealers should take great care in the manufacture of tea and thus maintain the reputation of the Japanese product.

The total quantity of new tea arrived from various quarters and now in Yokohama is said to be about 400,000 cutties.—*Japan Times*, May 18.

The quantity of tea leaves turned out from tea-farms in Uji districts is said to average 100 *kwamme* per *tan*, the profit being about 15 *yen* if sold in the raw state and about 25 *yen* if sold in manufactured state. The quotation of the tea farms is about 60 *yen* per *tan* in Soraku and Tsuzuki districts, but in the vicinity of Kohata, the centre of the favourite "Gyokuro" (Pearly Dew), the average price rises to five or six hundred *yen*, the highest being 800 *yen* and the lowest 200 *yen*.—*Japan Times*, May 19.

The following are some further items about tea industry in Uji:—A factory generally contains firing-furnaces ranging from 15 to 20 but sometimes as many as 80. One man manufactures one *kwamme* (a little over 8½ lb. Av. of tea out of five *kwamme* of raw leaves. The wages of these labourers are 30 *sen* per day with board. It takes a female tea-gatherer a day and a half to pick enough leaves for a male tea-firer to manufacture in a day. The daily wages of female labourers are 15 *sen*, average. Advances are made to these females as early as January, and when the season comes elderly women bring a

bevy of girls and inspect their work. The girls all put on their heads white *tanuqui*, they wear *taski*, the colour of which differs according to the age, those below 20 be red and those over 20 light blue. A new kind of tea called *tancha* (a lump of inferior tea pressed and hardened, and to be used by shaving) was recently originated. About 6,000 cattles of this tea was manufactured last year principally for exportation to Vladivostock. The result being satisfactory, it is intended to increase the manufacture of this kind of tea.—*Japan Times*, May 21.

AGRICULTURAL EDUCATION.

Those who have followed even cursorily the correspondence which from time to time breaks out in the daily and weekly press on technical education, must have become aware of prodigious gulf that lies between the ideas of foreign nations and our own on the subject of scientific knowledge. With us it is scarcely suggested, far less taught, in schools; it is just barely recognised in our Universities; in ordinary society any allusion to it is counted pedantic, in the Legislature it only appears when some restriction is to be placed on its exercise; and in the executive departments it only finds place for one chemist in the Custom House, and another in the Excise. As a consequence, or an illustration, of this universal neglect there is scarcely a single manufacturer who resort to scientific research as a method of advancing his interests, and the small amount of knowledge which is actually employed is almost limited to the purposes of detecting adulteration in materials purchased, and calculating proportions of ingredients in compounds. But abroad, whether we look to large States, such as France or Germany, or to small ones such as Denmark and Switzerland, the case is as different as day from night. The common schools teach every child the elements of the knowledge of things around him, that is of physics and chemistry. The Universities have large endowments for scientific training and research. Institutions exist for giving the instruction requisite in every special department of industry. Manufacturers recognise that there is profit to be made not only in routine methods, but in new discoveries and improved processes and they pay high salaries to men engaged in what to us seem the unpractical and absurd idea of merely discovering new truth. But the consequence is that they drive us out of the foreign markets and invade our own, that their progress treads everywhere on our heels, even if it does not leave us behind; and that though the volume of their transactions may not yet surpass ours, they are advancing in a far more rapid ratio.

In the department of agriculture the same difference of system is apparent. In Great Britain the State does absolutely nothing for it. Abroad, for the last half-century at least, the State has maintained numberless establishments for learning and for teaching the scientific facts on which agriculture in all its branches depends. The knowledge thus gradually built up is disseminated by reports and journals. In America the same system has been adopted; every several State has its experimental station, which publishes an annual "bulletin" of results ascertained by its scientific, that is to say, its exact, inquiries. Very lately we have seen the statement, which may perhaps not be precisely true, but which, at least, shows the mental attitude of American farmers, that within a radius of twenty miles of each State station there is no agricultural depression, so much have its object-lessons aided those within its sphere of influence to adapt themselves to their new conditions. For those who are more distant there are, besides the bulletins issued, not a few books in which the latest practical results of American and German scientific investigations are embodied.

It is a further remarkable fact that not only in such foreign sources is the information on scientific agriculture at present to be exclusively found, but that till lately it could be obtained only by ordering the books from the countries in which they were published. The American works were, of course, written in English, but no English bookseller thought them

worth showing to his customers. Armsby and Stewart two household names on the other side of the Atlantic as teachers of the principles of feeding stock, were utterly unknown here. The German works were not even translated, nor could any reference to them be found except in the excellent little manual of "Agricultural Chemistry," by Mr. Warrington, now Sibthorpian Professor of Agriculture at Oxford. But this lamentable hiatus in our literature has been partly filled by the publication last year of a translation, by Mr. Herbert Cousins, of Professor Wolff's treatise on the "Rational Feeding of Farm Animals." Still more recently we have a translation, by Dr. Aitken and Mr. Wright, of Professor Fleischmann's *Book of the Dairy*. At last, then, the English farmer has the access, in these two works, to the soundest and best guidance in the two departments which they cover. If he will only read and digest them, he will not merely gain knowledge, but direct money profit as well; for what they contain is the knowledge how to reach the results he seeks with the least expense at the smallest risk, and to the highest advantage.

We are, indeed, perfectly aware that the excellent works we have recommended will, to a large extent be beyond the comprehension of the great majority of those who, as agriculturists, have a direct interest in their subjects. But this melancholy truth only makes stronger the case for giving serious consideration to the treatment of scientific education in this country. If farmers and landlords are as a rule so ignorant of the mere elements of science that they cannot understand books which treat of the business of their lives, it is obvious that there is something radically wrong in the education which they receive. And if they and the Government, which is in a great degree subject to their influence, are unable to see the importance of coming up to a level with the technical knowledge enjoyed by their foreign rivals in every department of industry, it is absolutely certain that year by year they will find themselves further outstripped in the race of competition, in which victory, by Nature's inevitable law, falls to those who are able most deeply to penetrate her secrets.—*The Melbourne Leader*.

THE "AGRICULTURAL GAZETTE" OF NEW SOUTH WALES.

We have received from the S.N. Wales Govt. Printer a copy of this *Agricultural Gazette* for April. The Chemist, Mr. F. B. Guthrie, has a valuable article on the fertilising value of bonedust, and the information given should be of interest to those who go in for that manure. Dr. Cobb's contribution is a long series of letters on subjects embracing Wheat—varieties and nomenclature—Diseases (smuts burnt; white-heads); Maize Rust; Disease of the Plum Apple (bitter pit, canker); Potato (wet rot, scab) Orange (Melanose [?] mal di goma, verrucosis, die, back, blackspot); Peach and Nectarine (peach freckle, curl, the crease in peaches); The Gall-worm; Disease of the Grape; Onion; Timber Diseases; Preparations and Use of Bordeaux Mixture; Compound Mixtures; Drying Fruit for Home Consumption.

All the diseases, &c., are illustrated by means of excellent blocks; and as the Doctor has been careful to express his ideas in the plainest possible language the contribution is of extreme interest, and should be carefully read by all engaged in wheat-culture and the treatment of diseases of orchard and farm crops. A chapter on the diseases of timber is instructive, while for the information of those who desire to try the various sprays recommended, the Doctor's suggestions concerning the preparation of the mixture should prove useful. Those engaged in fruit-drying should note the remarks concerning the use of sulphur fumes. Mr. W. L. Boyce, of Lochinvar, recounts his experience of feeding cattle on holed prickly-pear. The poultry expert, Mr. McCue, takes up cudgels on behalf of pure strains of table and laying fowls. Mr. Allen, the new fruit expert, has some notes for the guidance of persons planting orchards, and there are many other interesting items.

THE EAST INDIAN AND CEYLON TEA COMPANY, LIMITED.

The following is from the Report presented at the second ordinary general meeting of the company held on Tuesday last:—

The accounts were duly closed up to November 30th, 1895, from the various dates the company obtained possession, and the bulk of the profits were utilised in payment of interest to the vendors as provided in the prospectus, the balance being carried over to the company's credit as stated in the circular issued to shareholders November 30th last. For the year from December 1st, 1895, to November 30th last the accounts have not just been closed and audited. The crop amounted to 1,529,384 lb., and this has realised £48,576 3s. 2d., or an average of almost 7½ per lb.

The expenditure on the bearing estate amounted to £36,411 2s 9d, and the profit of the year's working was £12,656 16s 2d. The amount at credit of profit and loss account after crediting the balance carried over from last year and deducting income-tax, is £12,762 9s., from which dividends have been paid on the preference shares to November 30, 1896, amounting to £5,103 5s 2d, as we as an interim dividend on the ordinary shares of £2,550. This leaves a balance £5,109 3s 10d. The directors recommend that a further dividend at rate of 4 per cent making 7 per cent for the year, be now distributed to the ordinary shareholders, and that the balance of £1,709 3s 10d be carried forward. Sixty-nine acres were planted on the old estates during the past year, and the cost of this as well as of the upkeep of 67 acres planted in the previous year, amounting in all to over £900, has been charged to revenue. In addition to the above-mentioned expenditure it will be seen from the accounts that £4,853 17s 3d has been spent on developing the Hapugasteune estate, and has been charged to block. The properties in India and the bearing properties in Ceylon have been duly conveyed to the company, and legal transfer of the lands recently acquired in Ceylon is expected to be completed in the course of the next few weeks. The reports from the company's properties in India are satisfactory, and, as indicated in the prospectus, arrangements have been made for their more economic management. The European staff on the company's estates is an excellent one. Recent reports on the company's bearing estates in Ceylon are most encouraging, and by the higher system of cultivation introduced, and the judicious application of manures, an increased yield may be confidently expected. In order to ensure more economical and efficient working, arrangements are being made for the acquisition of a site where water power will be available for a new factory at Mahaousa. The directors have recently purchased 421 acres of land in Ceylon at R36 per acre, and they have sold a small outlying block of 444 acres at R75 per acre.

The exchange of lands with the Government has been carried through, and the directors are glad to be able to report that the company stands possessed of 4,770 acres, or thereabouts, of fine land in Ceylon over and above the old bearing estates, the judicious development of which will be of the very greatest value to the company. During the past year 270 acres of tea have been planted there, and a further extension of 1,300 acres is being made in 1897. Thanks to the energy and ability of their colleague, Mr. Davidson, and the superintendent, Mr. Imray, the progress of this considerable work is well advanced, and is every way satisfactory. To meet the heavy expenditure in connection with these extensions it will be necessary to issue balance of the capital—viz., £30,000. From reports received the directors think it probable that to do justice to this fine property it will be desirable to increase the capital of the company and perhaps to amalgamate, so far as concerns these new lands, with a neighbouring proprietor. These important questions are now under the careful consideration of the board of directors, and after con-

sulting personally with Mr. Davidson, they will bring a definite proposal before the shareholders. The directors are alive to the importance of also cultivating products other than tea, such as rubber, Liberian coffee, fibres, etc, the experiments on a limited scale have been sanctioned and are now being made. They are also encouraging as much as possible all practical efforts to open up and extend new markets for tea, and they are glad to report that 331,199 lb of the company's 1896 were crop disposed of in America and Canada.

The second ordinary general meeting of the shareholders of the East India and Ceylon Tea Company, Limited, was held on Tuesday at Winchester House, Mr. S. Boulnois presiding. Mr. W. T. Jones having read the notice convening the meeting.

The CHAIRMAN said: Before asking you to adopt the motion for the passing of the report and accounts, I wish to explain why I am somewhat unexpectedly called upon to preside today, and to occupy the position of our worthy chairman, Mr. P. R. Buchanan. I shall read to you the letter which I have received from him, and which will be of interest to all the shareholders. It is as follows:—"My dear Boulnois,—As the report of the East India and Ceylon Company is so good, and as everything is in a most satisfactory and promising condition, I have no hesitation in asking to be excused from presiding at the annual general meeting. As you know, I am in the hands of the oculists, and the rapidly increasing failure of eyesight precludes me, except under very extraordinary circumstances, from taking part in any public meeting. If we had anything disagreeable to communicate to the shareholders I would have made a point of being present, but in the present satisfactory circumstances I feel I may honourably ask to be excused. You are, I think, aware that the oculists hope to perform a fairly successful operation, but it will be a long business, and the result can scarcely be known before the end of the year.—Believe me, &c., Pat. R. Buchanan." That letter, Mr. Boulnois continued, speaks for itself, and I am sure you will all cordially agree with me that we are exceedingly sorry to hear of the affliction of our chairman. Now, as to the report, which I presume you will take as read, I shall be very brief in my remarks, because we have made it as exhaustive as possible; and, moreover, we have present with us our colleague, Mr. Davidson, from Ceylon, who will be able to give you much more information regarding our properties than I can be expected to do. In paragraph 2 you notice that the accounts were duly closed up to November 30, 1895, from the various dates the company obtained possession, and the bulk of the profits were utilised in payment of interest to the vendors as provided in the prospectus, the balance being carried over to the company's credit as stated in the circular issued to the shareholders November 30 last. It may interest you to know that the total amount of balance was £672 17s 9d, of which sum £326 19s 9d was not available for distribution. For some reason our lawyers said we must not distribute that; that as a capital account we could not distribute it, and therefore we carried that to the sale of land and purchase account—to the credit of the purchase account of the properties. £345 18s, the balance, was brought to the credit of the profit and loss account. Going a little further we find a satisfactory feature of the account is that we have charged to revenue 69 acres that were newly planted out on the old estates during the past year, and we have also charged the upkeep on the old estates, for the young tea on the same estates, machinery, buildings, coolies, &c. By this we may estimate at least £1,200 have been charged to revenue account that in under certain circumstances might have been charged to the block account or capital account, but we thought it more prudent to charge it to revenue. I will not touch upon the matters as to our Blackwater and Mahaousa estates, because Mr. Davidson is here and

will tell you all about them, but there is an item in the accounts I have been asked about, and it is a point which anyone not conversant with the way in which tea accounts are kept may be at a loss to understand; therefore I shall explain it. You will find the item "Tea unsold on November 30." That has since realised £18,758. That is the amount we now know that it has realised, but at November 30 it was, of course, not sold. We have now at May 14 that amount in money instead of tea. There is another small amount we had to estimate subsequent to May 14. The small amount then remaining unsold had to be estimated, and was taken at £5,803. This has now all been sold, and has exceeded the estimate by £51, so that we came pretty near what it was likely to bring. The report goes on to refer to the expenditure on opening the new lands.

The balance of our capital, £30,000, will very shortly be wanted, and we shall propose to offer the shares, *pro rata*, to the existing shareholders. We take it that that will be the fairest way of doing it, though really it is not a very large amount. Coming now to the question of amalgamation with a neighbouring proprietor, we only foreshadow that in the report, and anything that I might say now would, perhaps, not be to our interest. However, I may tell you that various methods for working the new lands are under the consideration of the directors, but in the present stage of the negotiations it would be highly undesirable in the interests of the company to say any more on the subject than we do in the report; but as soon as we are in a position to lay a scheme before you we shall call you together to discuss the whole subject. The amalgamation, you clearly understand, refers to the new lands; the old property and estates will continue as before in their present state. To open up 5,000 acres of land is rather a tall order, and that cannot be done without more money. As to the prospects of the current season, I may say they are very good. You will be glad to hear that the quantity of tea made to the 15th of this month is about 40,000lb ahead of the same period of last year; but larger production may mean lower prices, and therefore it will not be well to attach too much importance to this fact. At the same time we see no reason to expect that the current season's results should not at least be as good, if not better, than last year's and for this reason, among others, that the present rate of exchange, which was against us nearly all through last season, has now turned more in our favour. I now beg to move: "That the directors' report and the accounts having been circulated, the same be adopted, and the dividend declared on the ordinary shares at the rate of 4 per cent., making 7 per cent. per annum for the year, be paid, and that the same be made payable on the 31st inst."

Mr. L. DAVIDSON, in seconding the resolution, said, he desired to make a few remarks on the general working of the estates. The cultivation of the Blackwater and Mahausa old estates had been somewhat altered recently. They were now going in for manuring, which, in his opinion, would produce more profit to the shareholders. The increase of crops next year would no doubt be very large, and when they got manure in regular rotation they might expect greater returns in coming seasons. The Government lands that they acquired last year were, he considered, the most important possessions of the company. They were aware that they bought about 2,700 acres of land from the heirs of a gentleman deceased. The Government were desirous of acquiring one block of that land, amounting to 1,200 acres, the reason being that it lay in the heart of a large block in the reserve forest, and that it also affected the rainfall of that side of the country, which was one of the driest parts of Ceylon. He approached the Government Commissioner, and they arranged to make an exchange, the one portion of the bargain being suitable to Government purposes, and the other to the advantage of this company. Plans of these properties had been sent home from Ceylon recently, and any of

the shareholders would from them understand clearly the position of affairs. The land they got made a large block of 5,000 acres, almost without a break. It lay along a valley, through which they hoped in the near future to construct a cart road or tramway, which would practically tap the estates all the way through, and thus give economy in transport. He understood the directors would very shortly come to a decision regarding this road, probably joining with other companies in the expense of its formation. The total cost would not be large. The land in question was first-class in character, and when fully developed not only would it be the largest in Ceylon, but one of the finest properties at a medium elevation. As to the staff in Ceylon, he might say they worked splendidly, and he had every reason to be proud of them.

The resolution was agreed to unanimously.

On the motion of Mr. C. T. RICHARDSON, seconded by Mr. F. G. PRIDEAUX, Messrs. Bouinois and Bryans were re-elected directors.

Messrs. Woodman, Tulloch, and Edds were re-appointed auditors, on the motion of Mr. H. A. HADRILL, seconded by Mr. J. W. SCOTT, and the meeting was brought to a close with a vote of thanks to the Chairman and Directors.—*H. and C. Mail*, May 28

OTHER TEA COMPANIES

SOUTHERN INDIAN TEA ESTATES.—Dividend of 5 per cent. making a total of 10 per cent. for the year. As a large area of valuable land belonging to the Company is at present unproductive, the directors consider it desirable that some of it should be quickly brought under cultivation, and for this purpose it will be necessary to issue this year 300 new shares—say 200 6 per cent. preference and 100 ordinary shares, which it is proposed be first offered to the shareholders *pro rata* at 10l. 10s. per share.

TINGRI TEA COMPANY, (LIMITED).—The report for 1896 shows that the profit on the seasons operations amounted to, including 161l. brought forward, 4,220l. The directors recommend a dividend of 6 per cent., carrying forward 830l. Owing to more unfavourable rates of exchange for remittances to India, the increased cost under this head amounts to 729l. In consequence of the high prices ruling for rice, the importation for the consumption of the labour force has been carried on at a loss of 492l.

RAJMAI TEA COMPANY, (LIMITED).—The report for 1896 states that the profit on the season amounted to 3,463l. A balance of 5,410l. was brought forward. The directors recommend a dividend of 5 per cent., making, with the interim dividend paid in November, 10 1/2 per cent. for the year, leaving 4,773l. to be carried forward. The negotiations for the purchase of the Borbarie Estate were satisfactorily concluded.

BRITISH INDIA TEA COMPANY, (LIMITED).—The annual report states that the net profit amounted to 5,362l. The directors propose to declare a dividend of 5 per cent. for the year on the ordinary shares, and to carry 2,098l. forward.

JHANZIE TEA.—Final dividend of 6 per cent., making 10 per cent. for the year, which will absorb 5,019l., carrying forward 1,069l.

MAJULI TEA.—Account for past year show profit on season, 4,976l.; balance brought forward, 2,425l. The directors recommend a dividend of 5 per cent., with a balance carried forward of 2,606l. Although the crop of the past season failed to reach the manager's estimate, the total exceeded that of the previous season by 68,066l.

DARJEELING CONSOLIDATED TEA.—The ordinary general meeting of the Company was held on May 17th at Winchester House. Sir Alexander Wilson presided, and said that he hoped the shareholders would consider the results of the past year as satisfactory under the circumstances, considering the exceedingly poor seasons that most of the Darjeeling companies had experienced. The board proposed a dividend on the ordinary shares at the rate of 4s. 2d. per share. The report was adopted, and the dividend approved.

OUVAH COFFEE COMPANY, LIMITED.

CAAPITAL £100,000 IN 10,000 SHARES OF £10 EACH.

Directors Alfred Brown, Managing Director. L. Famin, Norman Stewart, P. C. Oswald.

Report to be presented to the second Ordinary General Meeting of the Company, to be held at No. 5, Dowgate Hill, London, on Friday, the 4th day of June, 1897, at 12 o'clock noon.

The Company, as Shareholders were informed at the Statutory Meeting held on 17th November, 1896, has been satisfactorily reconstructed, with a new Memorandum and Articles of Association, containing the additional powers required for the conduct of the Company's business.

The following Annual Accounts are now presented to Shareholders, viz.:—Profit and Loss Account for Crop 1895-6, Balance-sheet made up to 31st March 1897. crop 1895-6

In last year's Report it was stated that the Coffee Crop of the above season would be small, and it will be seen that the actual weight sold in London amounted to 376 cwt. 3 qrs. 13 lbs.

The proceeds amounted to £1,735 13s 3d, giving an average of 92s 2d per cwt., against an average of 93s 5d, obtained for the previous crop. Coffee sold in Ceylon realized £22 18s 11d.

The crop of Tea was estimated at 606,000 lbs., and the actual weight sold from the Company's own estates was 570,360 lb. Besides this 135,608 lb. of Tea manufactured from leaf bought from neighbouring estates were sold.

The value of all Tea sold was £23,907 5s 11d, at an average of 9'15d per lb., as compared with 9'08d. for the previous season.

Cocoa, weighing 141 cwt. 0 qrs. 3 lb. realized £330 16s 7d, the average selling price being 46s 11d per cwt. against 48s 9d for the former year's crop.

It will thus be seen that the total value of all produce sold amounted to £28,997 14s. 8d.

The total Expenditure for the year in Ceylon and London amounted to £23,932 10s. 8d., and deducting this from the value of the Produce, a profit is shewn on the season's working of £5,015 4s. 0d. To this has to be added the sum of £1,151 1s. 9d., being the undivided profit transferred from the old Company, giving a total of £8,166 5s. 9d. at the credit of Profit and Loss Account.

An Interim dividend of 3 per cent. on the capital of the Company was paid on the 7th November last, which absorbed £3,000 of the above-named sum, and the Directors now recommend that £3,000 be applied to the payment of a further dividend of 3 per cent., making 6 per cent. for the year, and that the balance of £166 5. 9d. be carried forward to next Account.

The smaller profit secured as compared with last year is entirely due to the shrinkage in the Coffee crop, the proceeds from the sale of this product having amounted to only £1,759 12s. 2d., against £5,796 6s. 11d. for the preceding year.

The Coffee crop for 1896-97 will again be a very small one. Reports on the present condition of the Coffee bushes are at the moment more favourable, but no reliance can be placed on this crop as a source of revenue.

The estimated Tea crop was not fully secured, but the satisfactory yield of 400 lbs. per acre from the whole area plucked, inclusive of that only in partial bearing, was obtained.

The Tea sold well at a small advance on the price obtained for the previous year's crop, notwithstanding that the average for all Ceylon Tea on the London market declined 3d. per lb. during 1896.

Since the date of last Report a further 150 acres of Tea have been planted, bringing the total area under that cultivation up to 2,007 acres as detailed below. Further plantings will be limited to replacing Coffee with Tea, as the former has to be abandoned.

The Tea crop for 1896-97 is estimated at 650 000 lb. of made Tea. So far pluckings have been heavy and crop prospects are good.

Mr. P. C. Oswald, a Member of the Board, retires on this occasion, and, being eligible, offers himself for re-election.

Messrs. Deloitte, Dever, Griffiths & Co., the Auditors, also offer themselves for re-election.

By order, J. ALEC ROBERTS, Secretary.

May 26th, 1897.

SPRING VALLEY COFFEE COMPANY, LIMITED.

Report to be presented to the Thirty-second Ordinary General Meeting of the Company to be held at No. 5, Dowgate Hill, London, on Friday, the 4th day of June, 1897, at 12'45 o'clock p.m.

The following annual accounts are now presented to Shareholders, viz.:—

Profit and loss accounts for crop 1895-6.

Balance Sheet made up to 31st Earch, 1897.

crop 1895-6.

In last year's Report Shareholders were informed that the coffee crop of the above season would be very small, and it will be seen that the actual weight sold in London amounted to 298 cwt. 1 qr. 12 lb. This crop, inclusive of clean and refuse coffee sold in Ceylon, realised £1,353 4s. 1d., the average selling price being 90s. 2d., as compared with 91s. 10s. per cwt. obtained for crop 1894-5.

The yield of Tea amounted to 250,171 lbs., the estimate in last Report being 230,000 lbs., and this, together with 74,350 lbs., brought from neighbouring estates and manufactured at Spring Valley, sold for £12,284 10s. 6d., or an average of 9'08d. per lb., the average selling price last year being 9'34d. per lb.

The total proceeds from the sale of produce amounted to £13,637 14s. 7d. The total expenditure in Ceylon and London, including outlay on planting 145 acres tea and maintaining a large area of young tea not yet yielding crop, amounted to £14,077 12s. 4d. Profit and Loss Account has therefore to be debited with a sum of £439 17s. 9d., being expenditure in excess of the year's revenue.

The sum of £2,594 17s 2d was brought forward from last year, so that after making provision for the above amount the balance at the credit of profit and loss is £2,154 19s 5d, and provided that Shareholders elect to adopt the proposals to be submitted to them at the Extraordinary General Meeting to be held immediately before the Annual Meeting, the Directors recommend that a dividend of 2½ per cent. be now declared for the year, leaving £154 19s 5d to be carried forward to next account.

The revenue from coffee, as stated above, only amounted to £1,353 4s 1d., against £7,616 3s. 11d. for the previous year. The estimate for the current season is 200 cwt., and it is feared that all hopes of profit from this cultivation must be finally abandoned.

The Tea Crop did not come up to expectations, 250,171 lbs. having been secured, against an estimated crop of 230,000 lb. Prospects from this cultivation, however, remain good, and this year's crop, estimated at 311,000 lb. is likely to be considerably exceeded.

Since the date of last Report, 159 acres of unproductive coffee land have been planted up in Tea, bringing the area under that cultivation up to 1,520 acres as follows:—

	TEA.	Acres.
Over 5 years old	741
Planted November/December	1892

..	95
..	96
Arca under Tea	1,520
Area under Coffee	406
Area under Fuel	56
Forest Patana and Waste	271
Total Area	2,253

The Directors desire to call the attention of Shareholders to the accompanying circular and notice of an Extraordinary General Meeting for the purpose of considering and, if thought fit, passing proposals for the more rapid development of the Company's property at a Tea Estate.

Mr. N. Stewart, a member of the Board, retires on this occasion, and, being eligible, offers himself for re-election.

Messrs. Deloitte, Dever, Griffiths & Co., the Auditors, also offer themselves for re-election.

By order, J. ALEC ROBERTS, Secretary.

May 26th, 1897.

PRODUCE AND PLANTING.

PARLIAMENT AND THE TEA DUTY.—The discussion on the Finance Bill in the House of Commons last week gave rise to further talk about the tea duty. In the course of the debate Sir William Harcourt, referring to the manner in which the Chancellor of the Exchequer had dealt with the surplus at his disposal, expressed his opinion that the indirect taxation of the country ought to be further reduced. For his own part, he said, if he had £2,600,000 to dispose of he would take twopence off the tea duty, thus reducing it to one half. If Sir William Harcourt should ever be in the position to carry out this good intention he will, we hope, bear this statement in mind.

THE ATTEMPT TO REVIVE THE CHINA TEA TRADE.—Now, according to the prophets, China won't be long. The opinion passed by experts on this side who have been asked to taste and see the machine-made teas sent over here is said to be so favourable that China tea men are in a great state of jubilation in consequence. One firm of Edinburgh tea dealers say: "We have pleasure in reporting to you on the sample (machine-made, isn't it?) China tea (new method) same as was sent to us by another firm of China brokers. We will say to you, much as we said to them, that were we China merchants we should certainly see that all the stuff we shipped should be made as this is made, instead of as all China has been treated for—how many years past shall we say? If John Chinaman sends home all his tea as strong as this, he will very soon give a good account of himself against the overwhelming flood from India and Ceylon, because there is in this sample much more of what the public consider the style and taste of tea than in much of the woody tasted stuff that comes from many of the Indian estates especially." That "machine-made, isn't it?" looks as if the Edinburgh people were rather doubtful on the subject. From the fervent hopes and sanguine views expressed about the Celestial teas, and the remark about the "woody-tasted stuff that comes from many of the Indian estates especially," it may be inferred that the Edinburgh firm are by no means averse to the revival of the China tea trade. The verdict thus passed is commented on as follows by the *North China Daily News*, which says: "If ordinary third crop Peking leaf is susceptible of such improve-

ment as is recorded in the letter of Messrs. Melrose, what possibilities are in store for teas prepared according to the 'new method' from first crop leaf from the leading districts in Yangtze Valley? It is to be observed that it is not for the resemblance to Ceylon and Indian teas that Messrs. Melrose view so favourably the samples submitted to them, but because they are considered to have the style and taste of tea. It is to be hoped that the Chamber of Commerce will not confine the observations they are preparing to publish to the tariff question alone, but will use their influence towards getting Sir Claude MacDonald, the British Minister to urge the Tsungli Yamen to take up the question of making Chinese congenial according to the methods that have rendered Ceylon tea so popular." It seems from the Indian and Ceylon planters' point of view at least, rather rough on them that a British Minister should be urged to encourage Chinese rivals to imitate their successful methods.

CHINA AND TEA MACHINERY.—The effort to place the production of Chinese tea on a better footing was referred to at a meeting of the Royal Botanic Society of London held on Saturday. A paper was read by Dr. Robert Boxall, who has travelled in the tea-producing districts of China, and was listened to with marked interest by a large attendance of Fellows, among whom were the Duke of Rutland and the Marquis of Bute. Dr. Boxall illustrated his paper with a fine collection of lantern slides, prepared principally from Chinese paintings, and exhibiting the various processes of planting the tea shrub, and the cultivation, gathering, and preparation of the leaf for the market. From the time of the first imports of tea from India the quantity of China tea brought into this country has diminished year by year, and it now seems to have dawned upon the Chinaman that unless he brings himself more into line with his competitors the British market will soon be all but closed to him. He is, therefore, importing large quantities of machinery, and great preparations are being made to produce teas of such fine character as will once more gain them something more than a foothold in the British market.

TEA IN THE UNITED STATES AND CANADA.—The tea market has been surprised by the fact that an expected duty of 5c. per lb. has not been included in the Canadian tariff, and still more by the announcement that the United States Senate Committee has included a duty of 10c. per lb. on tea until January 1st, 1900.

COOLIE LABOUR AND THE STRAITS SETTLEMENTS.—The Penang and Province Wellesley planters do not like the Immigration Bill at all. This Bill abolishes the punishment of such Indian immigrants as arrive under advances and refuse to sign labour contracts. The matter arises through the Indian Government's proposing to obstruct emigration unless the penalties are abolished. The planters do not desire to recover from the coolies the money advanced for their passage, but say that they cannot make advances unless the coolies, on arriving, are bound to sign contracts at the agreed statute labour rates. The planters have resolved to address a memorial to Mr. Chamberlain.—*H. and C. Mail*, May 28.

COONOOR, June 10.—The S. W. monsoon currents have set in but no high winds experienced yet, but temperature fallen greatly. Leaf-disease touching up the coffee here and there. Tea still flushing grandly. Has been a marvellous year for tea, and few, if any, of the totes have managed to save the whole of the flush, owing to scarcity of pluckers. Labour fairly abundant on the whole, but advances in some cases have been raised to 5/8 per head: a rise of 8 as. I saw a specimen of *Ceylon Erythrina lithosperma* the other day 3½ feet high, at 6,000 feet elevation, but in heavily manured soil.—"Planting Opinion."

FACTS ABOUT TEA.

We have a strong appeal from London to the tea planters of Ceylon to drop "broken" teas—"our average now," says one critic, "would be as high as two years ago but for the fall in broken pekoes."

Messrs. Wm. Jas. & H. Thompson send us their annual Tea Review, dated 9th June, which we hope to reproduce in full tomorrow—meantime mentioning that these eminent brokers take an encouraging view of the situation and prospects, pointing out how great is the room for an increase of consumption of tea per head in the United States (rate now only 1½ lb. per head against 5½ lb. for U. Kingdom, Australasia, and Canada) and still more in Russia, Germany, and the rest of the Continent. And why they ask (as we have often done) should the commoner teas not be drunk universally by the people of India (and Ceylon), as tea is by the Chinese and Japanese? Why not indeed, save for the people's poverty. But at least most of the money invested in arrack might well be transferred to tea, if proper encouragement and opportunities were afforded. Messrs. Thompson dwell on the growing enquiry for *fine-flavoured* tea, and how this must tell in favour of high Ceylons. Finally we read:—

The needs of the day are to bring tea rapidly to market; at regular intervals; in as large breaks as can be made; sub-divided into the four or five recognized grades; to break the leaf as little as possible by mechanical process; and to maintain the distinctive character of the garden's produce.

As to average prices, Messrs. Thompson find for Ceylon tea in London as follows:—

Showing the progress of the Ceylon Tea Trade in London:—

Season ending 31st May	Imported lb.	Sold in Auction pks.	Average price per lb.
1887	8 million	124,000	1s 1½d
1892	64 "	790,000	9½d
1897	93 "	1,095,000	8d

While for the North India districts, the following results are worked out:—

Returns for	Acreage.	Quantity. lb.	Per Acre.	Average Price per lb. d.
1895-96 ..	101,750	45,850,000	450	9 55
1894-95 ..	97,120	42,284,000	435	10 55
1893-94 ..	91,300	40,083,000	439	9 65
1892-93 ..	85,780	34,900,000	406	11 30

It is interesting to learn from Messrs Gow, Wilson & Stanton that the Indian Tea industry is generally dated from 1837—the year in which our coffee-planting on the West Indian system in Ceylon first took its rise. Also that the tea consumption of the importing countries of the world equals 500 million lb.; while India and Ceylon produce not much more than half this as yet. We have a good deal of room for expansion therefore, if only we can drive out China's and Japan's. We have half conquered Australasia; but surely we (India and Ceylon—or Ceylon by itself) ought to complete the conquest: In North America, British-grown teas only made up *one-tenth* of the consumption last year: immense room here for expansion; and so also on the Continent of Europe. As to the improvement of our teas and the application of Chemistry, we think the larger and more prosperous tea concerns should lead the way! a competent analytical chemist added to the staff of one of our largest factories ought to be a profitable investment, and the cost of a three

years' engagement not too great to be faced, especially as he should be able to advise in other directions than in the fermentation and better preparation of tea.

PLANTING IN THE CENTRAL PROVINCE OF CEYLON.

NEW AREAS OF CULTIVATION.

I am indebted to the Secretary of the Northern Districts Planters' Association for the following observations and figures regarding the progress of European tea and cacao enterprise in this district:—

"Tea.—The area brought under new cultivation in Matale East is very small. In Matale West it is fair, but Matale North is putting a large area into tea, and promises to double its acreage in a few years' time. The yield of the three districts was fair, averaging about 460 lb. per acre, but the rupee prices were low owing to high exchange, and in spite of a favourable crop most estates show a reduction of 20 to 25 per cent. in their profits.

"Labour was more abundant than in most districts, but more estates were nevertheless short of requirements.

"Cacao.—The extension of this product has entirely ceased for three reasons:—(1) Lowness of price; (2) expense of protecting it from theft; (3) a disease which has latterly appeared and which no one understands. The disease kills the mature trees, and is not to be checked by the most careful system of cutting out and burning. The more highly cultivated the cacao is, the more liable it seems to attack, and the disease kills so quickly that the leaves have not time to fall. It is unlikely that there will be any extension of cacao until a remedy has been found for this disease. No statistics as to crop were collected."

As regards native enterprise, the extent brought under cultivation during 1896 may be roughly put down at about 500 acres, chiefly in cacao and coconuts, and nearly all in Matale South. The area under paddy cultivation does not appear to have been added to during the year, but there are no signs of any decrease consequent on the abolition of the paddy tax

THE "CRYPTOGAMIST" AND CACAO.

We ought, in dealing with the Governor's speech last week, to have noticed the fact of the scientific gentleman, who is so difficult to name after dinner, having been amongst us before, and that, at an Old Colonists' gathering he should seem like an "old chum." When Professor Marshall Ward came to Ceylon to investigate the coffee-leaf fungus, he necessarily arrived amongst us bearing what in Scotland would be called a "long-nebbed" title. His professional cognomen, we remember, struck awe into the hearts of many, and excited the imagination of some. One story, current at the time, was that an old planter who seldom left his estate, having failed to get any kind of satisfaction as to what a "Cryptogamist" was like or what he did, determined to find out for himself. He journeyed into Kandy and out to Peradeniya, on this special errand, and went back again in high indignation that so small a man as Professor Marshall Ward should be permitted to assume such a high-sounding, not to say awe-inspiring, title! Since 1881, however, Professor Marshall Ward has climbed very high, indeed, in the esteem of his scientific brethren through the continuously valuable work he has done. He is now one of the Professors at Cambridge University and is probably regarded as a "Cryptogamist" or "Fungologist" of the first rank—indeed, as a Botanical authority generally he has attained to that position.

To return to our cacao friends, we are assured by one of them that although there may be few in the profession (Cryptogamic) and the name may be fascinating, cacao-planters would be very glad to see one now at work, whatever his height in inches might be, or however much he might embarrass the language of the diner-out. On the other hand, we have other cacao estate proprietors who regard the existing troubles without anxiety. One such writes to us:—"The Helopeltis scare was, I consider, more serious than the present disease; and therefore, I think we may hope for an improvement in cacao prospects during the next few months."—It is becoming evident that proprietors in the more favoured districts, and who depend chiefly on the "Forastero" variety have not much to fear from the present pest or pests; and the older the trees grow, the less liable they will become to such attacks. Nevertheless, we trust the fullest scientific investigation may shortly take place, whether by Cryptogamist, Entomologist, or Economic Botanist—or all three together.

THE EADELLA ESTATES COMPANY.

REPORT OF THE DIRECTORS.

The following report was submitted at the last meeting in Kandy:—

The directors beg to submit to the shareholders their report for the year ending the 30th April, 1897, together with a statement of accounts and balance sheet for that period. The estates have yielded 94,560 lb. of tea, which quantity includes 2,681 lb. of tea made from purchased leaf. This shows a decrease upon the previous year's returns of 16,407 lb. This reduction is owing to the abnormal season, the North-East monsoon having been unusually wet for 3 months and followed by hard dry showerless weather. The prices realized for the teas were on an average 7 cents per lb. less than last year's, which in a large measure is accounted for by the lower rates of tea and higher exchange.

Cocoa.—There were secured 102 cwt. as against 145 cwt. last year. The wet weather of the autumn had the effect of blacking off the pods, otherwise the estimate would have been realized, as the pest prevailing in other districts is absent here.

LIBERIAN COFFEE reached the estimated quantity.

The balance or profit and loss account is R5,997-58, and the directors do not see their way to recommend declaring a larger dividend than 3 per cent. and to carry forward R1,197-58. The directors have to point out that expenditure has exceeded the authorized capital by about R9,000, and about R5,500 will be required for permanent works in 1897-98, so that it becomes necessary to provide R14,500 by increase of capital, or loan, as shareholders may determine at the ensuing general meeting. As a large amount has now been written off for depreciation on Factory machinery, it is considered that 5 per cent. this year will be sufficient.

The directors retiring from office are Messrs. W. D. Gibbon and E. S. Fox, and, being eligible, Mr. Gibbon offers himself for re-election. The meeting has to elect the Auditor for the year.

Acreeage.—221 Tea in full bearing, 98 Liberian coffee and cocoa, 102 coffee, cocoa, and coconuts (87)—50a 1 year old and 52a new. 151 forests. Total 572 acres.—By order of the Directors, J. Munton, Agent and Secretary.

Those present at the meeting were Messrs. W. D. Gibbon, E. S. Fox, A. M. White, Ed. Kynaston, H. S. Rix, Lieut.-Col. Duke, J. Munton and by attorney Buxton Laurie.

The Report of the Directors was not quite approved of, and after passing and approving the statement of accounts it was resolved that no dividend be

paid. The election of Directors resulted in Mr. W. D. Gibbon's re-election and Mr. A. Melville White was elected to the vacancy caused by Mr. E. S. Fox's retirement. Mr. J. Guthrie was re-elected Auditor.

A NEW TEA COMPANY.

The mail brings the news of the flotation in London of the Imperial Tea Company with a capital of £1,000,000 to purchase a group of gardens under the management of Messrs McLeod & Co. of Calcutta, viz.—

	£
Ring Tong	25,210
New Glencoe	41,900
Washabarie	20,460
Central Doocars	70,230
British	53,000
Jainte "	26,000
Sylhet Tipperah	46,000
Rema	36,000
British Sylhet	12,960
Kuttal	49,490
Monabarie	22,670
Tarajulie	35,000

438,920

The Ring Tong garden with 420 acres under plant is a Darjeeling concern; the next four gardens are in the Terai with 4,580 acres—the next three are in Sylhet with 2,418 acres; the Kuttal is in Caehar with 1,192 acres, and the last two are in Assam with 1,223 acres. There are thus 9,833 acres, under tea, the total area of the gardens being 34,685 acres. It will be observed that the Company will have ample funds for working and extending these gardens and buying other concerns.—*Pioneer*, June 8.

THE AMSTERDAM MARKET.

Our Amsterdam correspondent writes on May 27th that up to the present 4,193 bales and 120 cases of Java cinchona have been entered for public sale on June 10th. They contain about 353,180 kilos of Pharmaceutical bark, representing 2,070 kilos of sulphate of quinine, or the extremely high average of 5-78 per cent. The 25,457 kilos of Pharmaceutical bark contain 689 kilos of quinine. In the course of last year the average equivalent of quinine in the Manufacturing barks offered at the ten sales of that year amounted to about 30,770 kilos, so that the June auction shows a decrease in this respect of over 30 per cent. The average quinine-content of the first five auctions of the present year is 28,500 kilos, but this includes a considerable proportion second-hand parcels and several lots of bark imported some years ago. Considering that the first-hand stock of bark in Amsterdam has now sunk to 1,612 packages of Government and 1,054 packages of private plantation bark, including many parcels of very old import, the position of quinine may be considered to have undergone a decided change for the better within the past few weeks. Since the May auctions about 500 bales of Manufacturing bark, representing about 2,960 kilos of quinine, have been sold privately at prices exceeding the auction unit. Our correspondent also points out that the refusal of the combinet factories to sell quinine to any considerable extent has generally been the precursor of an advance in quotations on their part.—*Chemist and Druggist*.

"**JAPANESE GORAKAS**"—grown on Franklands, Veyangoda, are most attractive looking fruit with a colour and bloom not unworthy of apricots; but we cannot say as much for the taste and flavour of the inside, a "mangosteeu-rambutan" would be a fair description, the sub-acid reminds one of the latter fruit especially, but it is more 'woolly' and insipid.

Teas marked thus * are New Season. — Gov. Wilson & Son's Report.

WHY SHOULD THE CEYLON GOVERNMENT NOT EMPLOY AN AGRICULTURAL CHEMIST?

"In Barbadoes and Demerara there is a Government Chemist, why should not there be one in Ceylon?"—so writes a London Correspondent by a recent mail—and we can only echo the question, and ask—"Why not indeed?" Barbadoes has a population under 150,000; a general revenue of £165,000 or so, and an annual export trade under a million sterling; British Guiana has 260,000 people; £600,000 revenue and about two million sterling of export trade;—while Ceylon with over 3 million people, and a revenue approaching 1½ million sterling, has an export trade of over 4½ million pounds sterling. Surely then, we can afford a special Agricultural Chemist as well as the two minor Western Dependencies. It used to be said that the material progress—indeed the civilization of a community could be gauged by its importation and consumption of "sulphuric acid"! That had, of course, to do with a high state of cultivation of the land accompanied by such scientific guidance and experiments as Messrs Gilbert and Laves had made familiar in England. In Ceylon the time has fully come for agricultural experiments under the guidance of science. It will be remembered that Mr. Willis, in his Administration Report, the other day, specially hinted at desirable work which belongs to the Department of Agricultural Chemist. Now, His Excellency the Governor should know that there is a competent Chemist available in the island in Mr. M. Cochran—whose book ("Ceylon Manual of Chemical Analyses") is a standard work for local and planting reference—and we do not fancy that Mr. Cochran's duties in Colombo would hinder his taking up work with Mr. Willis, or in connection with our Planting and Agricultural Industries. The sooner he is appointed for such duties, the better for the material interests of the Colony; for there is no doubt that experiments of great value to our planters, and agriculturists generally, could then at once be instituted.

A CEYLON PLANTER'S VISIT TO SOUTH AFRICA:

CEYLON TEA IN JOHANNESBURG AND ALL OVER THE COUNTRY.

Reddersburgh, Orange Free State, May 16th, 1897.

We had a charming voyage from Colombo to Durban—no worry with a crowd of passengers and brass bands playing at meal and other times. The "Clerkeragi" is a strong, well-built boat, and Captain Roberts knows how to take care of his passengers, and landed myself and some others at Durban in 17 days in good condition. Durban was hot and a bit steamy—85° in the shade. I was rather glad to get away from the place, but it took me the most part of a week to see if any business could be done. The Natal-grown tea handicaps Ceylon as there is 6d per lb. duty on imported tea. They are all more or less interested in Natal-grown tea. It is the poorest stuff I have ever tasted in my life. This Natal tea is advertised and pushed beyond anything you can imagine. This is such an enormous country that it costs a lot of time and money to get about. I am in splendid health, however, and I can move steadily along. From Durban I went on to Pietermaritzburg, Ladysmith, Standerton, Heidel-

JAVA CINCHONA SHIPMENTS.—The exports of cinchona-bark from Java during the month of May have again been moderate. A cable received at Amsterdam on June 1st gives them at 640,000 half-kilos. The following figures show the totals for the past five years up to the end of May:—

Month of	1893	1894	1895	1896	1897
Jan. 1-May	Amst. lb.	Amst. lb.	Amst. lb.	Amst. lb.	Amst. lb.
May	714,000	900,000	402,000	768,000	600,000
Jan. 1-May 31	3,244,000	3,288,000	2,879,000	3,260,000	2,534,000

—Chemist and Druggist.

burg, and on to Johannesburg. I saw McLure & Co. They are doing good work for Ceylon and sell nothing but pure Ceylon tea. They have good tea rooms, which are crowded from morn till night. But settlers must be things in this country. That is to say, they are wholesale and retail and general merchants—all rolled into one. They will buy a bag of mealies and they can buy a 1,000 bags of mealies. The same with everything else. I had not tasted a cup of even passable tea until I got to Johannesburg and got some from McLure & Co. The tea and coffee in the hotels is vile stuff; and in nine cases out of ten, it is intended to be. A glass of whisky costs 1s, and a quart bottle of English beer is 4s. In most of the hotels that I have been in, there are men parading the dining rooms and calling out "Any orders for the bar?" So that with such prices for liquor you can easily understand why hotel proprietors are not working to push the sale of tea, cocoa or coffee. The P.A. will have to come to the rescue of S. Africa. There is an enormous quantity of tea used in the country and nearly all low-class Chinias. I have hardly seen any Indian and Ceylon tea although I have been in the country nearly a month I have seen very little of it. I go to Bloemfontein tomorrow, capital of O. F. S., and then on to East London. Charming country and such a climate! If you have never been in South Africa, come straight away; you will get enough material for your pen to keep you going for a very long time—and such a climate to settle in. Talk of Nuwara Eliya; it is not in it with such a climate as the Cape Colony, O. F. S. and S. A. R. The Kaffirs are fine big men and their women are big too for the matter of that. They are a cheery, good-natured lot of people. I have hardly any time to amuse myself—I have such a lot of writing and have to read up a lot to get along on my journeys in the best possible way. Good farms can be bought at 10s per acre. My brother has a farm of 12,000 acres, for which he paid £5,000—good for horses, cattle and sheep.

PLANTING NOTES.

QUALITY OF TEA.—A London businessman writes:—"I think the late Correspondence in the *Ceylon Observer*, must be regarded by all impartial readers as of particular merit, and with a really practical end in view. Seriously I think the matter requires immediate enquiry, for I hear from private friends in the Tea trade that Ceylon's are not what they used to be. I have heard that samples of soil and manure are now being freely analysed for tea-men in India and very few for Ceylon. This did not use to be the case."

JAMAICA ORANGE RECEIPTS IN NEW YORK.—The following statistics are from the *Fruit Journal*, and show the receipts of Jamaica Oranges at the port of New York for the past four years, up to December 1, 1896. Last year there was more than twice the quantity of Jamaica oranges received than the year previous, and three or four times as many as was received in former years:—

Receipts of Jamaica Oranges at New York, from September to May.

Year.	Boxes.	Barrels.
1892-93	7,688	43,050
1893-94	5,448	20,261
1894-95	13,296	88,951
1895-96	46,322	199,974
1896-97, to Dec. 1st.	25,928	180,777
		553,013

TEA BULKING.—"Senex" sends us some sensible, practical hints for the benefit of his brother planters on the subject of Tea-Bulking in a letter elsewhere. We commend what he says to the attention of those concerned. Everything that can conduce to careful accurate bulking in the factory, is of importance at this time.

THE COFFEE MARKET.—Is the following an indication of what may come to "tea" if the planting of "5,000 acres" by one Company here and there continues?—

—The *Triester Zeitung* represents the position of the coffee market to be utterly hopeless, and blames the Brazilian coffee-growers, whom it accuses, not only of under-estimating their crops, but of continuing to place their coffees on the market in ever increasing quantities, to the utter ruin of any chances of profit by their competitors. The recent reports of the extent of the Brazilian coffee crop have, according to this newspaper, completely knocked the bottom out of any hopes that the coffee trade was not in such a bad position as was represented to be the case. In the opinion of the *Triester Zeitung* there is only one thing which will remedy this state of affairs, namely, the formation of a strong syndicate to buy the whole of the present visible coffee supply of Brazil, and all that remains in the interior, and lock it up until better times come round. Our contemporary thinks that this operation would be by no means difficult at the present moment, and that a capital of £6,000,000 would probably be all that would be required to carry it out. Inasmuch as the *Triester Zeitung* thinks that large profits might be made by this scheme, it sees no reason why capitalists should not go into it.

The *Hamburger Handelsblatt* rather ridicules this proposal, and asks why, if there is so much money in the coffee trade, a proposal requiring £6,000,000 for its realisation should be made at all? It also suggests that schemes of this kind have more about them of the quack doctor than the legitimate practitioner.

A PRODUCTIVE GUAVA TREE.—The "minor industries" being the question of the day, I think it may interest you to know the output of one guava tree, of a very ordinary description growing in my place "Gully Castle." From the 11th February to March 11th, the fruit was gathered every other day and converted into jelly, stewed guava and sometimes dolce; of the two latter no account was kept as it was used at home and given away freely, but the jelly we kept an account of and at the end of the month during which it was being made we had got 50lb. when we stopped, a sit was a very good supply to keep us going for a long time. Since stopping, the tree has continued bearing abundantly, and I have no doubt but that an equal or even greater quantity could have been secured, but the birds have been having a good time, which judging from the numbers that come to the tree, must find it very welcome in these hard times, and I don't grudge the poor little beggars their enjoyment. The stewed guava and dolce I put down roughly at 20lb. and feel sure that I am under rather than over the mark: that gives 70lb. of preserves from one tree in a month. I don't know what figure the stuff sells at wholesale, but if one wishes a pound of guava jelly you must pay 1s 6d for it. I understand it does not cost 9d per lb. to manufacture, consequently if retailed a good profit would result. There are in some parts of the island an unlimited supply of guavas fit for converting into jelly, etc., and yet I believe guava jelly is actually imported from Barbados. We should be able to beat them at that, don't you think?—A. CAMERON MAIS, Kingston, April 8th, 1897.—*Journal of the Jamaica Agricultural Society.*

CACAO AND OTHER CULTIVATION AND THE "TROPICAL AGRICULTURIST."

Mr. E. E. Green, in the letter we publish on page 125, makes a valuable suggestion. It is that one general index should be compiled for the first ten volumes of our monthly periodical. But why confine it to ten? We are inclined, while about it, to make a complete index for the whole sixteen volumes which have now been published, the June number just issued finishing the last. In doing so, of course, care must be taken to omit reference to ephemeral matter of only passing interest, so as to reduce the bulk of the index and make it the handier for everyday use.

In reference to the Cacao disease described in Porter's "Agriculturist" in 1833, we have turned up the original book and find the author is referring chiefly to Mexico, though also to the Spanish States in South America; but no more is said on the disease referred to than we quoted in the T. A. In Mr. Hart's little Manual on "Cacao," besides the two greatest enemies of Trinidad planters—the Parasol or Umbrella Ant and the Cacao beetle, both fully described—and a fungus which sometimes attacks the pods, the chapter on "diseases" opens as follows:—

Fortunately for the cultivator the serious diseases which attack the Cacao tree are few, except the plant is placed in a totally unsuitable position. Perhaps the most common disease is one which is known under the name of Canker. This causes the stem and branches to dry in certain spots and along certain lines and generally results in the death of the tree. The cause and the remedy are not far to seek, for when trees are planted in good well drained ground, little or no Canker is to be found among them, but in poor surface soil, badly drained, with a hard subsoil in addition, Canker is sure to appear and to kill out the trees, for it is really the enervated condition of the trees which allows the attack to establish itself.

It is very probable that there are fields afflicted with canker—as seen by Mr. Green—and also others as described by several cacao planters, affected by a "poochie"—in some cases the *Tomicus perforans* as described by Mr. Van Der Poorten; in others perhaps by the cacao beetle or *Steirastoma histrionica*, WHITE, thus referred to by Hart:—

The attack is made by the beetle laying its eggs either in the crevices of the bark, or under the bark in holes made by the insect itself. The larvæ then work great damage to the tree by cutting long channels through the soft wood of the stem to such an extent that the slightest breeze breaks away the branch and destroys it, and sometimes the depredation of the grub is so great as to kill the tree outright. The only remedy which it appears can be suggested, is the collection of the beetles when out on their hymeneal tour, or when quietly resting in the crevices of the bark in the early morning hours. The larvæ may sometimes be destroyed by probing a stout wire into the hole where they have entered, thus impaling the creature at its work. This is not always possible, but where the life of a valuable tree is at stake, every endeavour should be made to arrest the destructive progress of the larvæ or grub, which can generally be found and destroyed without much injury to the tree, if a close and careful examination is made. In cutting out a grub, care should be taken to make the wound as small and as little jagged as possible, and to cover it at once with the mixture recommended in a former part of this work for covering the wounds made when pruning.

THE PROSPECT OF A RISE IN TEA.

The troubles of our planting friends in Assam—as reported in successive telegrams—if confirmed when details come to hand by post, cannot fail to influence the tea market both in India and Ceylon as well as in Europe. Here is what an observant colonist says:—

"These telegrams from India about the damage done in Assam by earthquakes to factories and roads and the comparatively small exports of tea from Ceylon to date ought to make tea rise. The most important telegram in respect of tea is that which states that it will take 2 months before tea can come from Assam to Calcutta in any quantity." There may possibly be a call on Ceylon planters to aid their brethren in Assam.

RICE IN KANDY (CEYLON).

We had an enquiry the other day as to the price of rice in Kandy this year as compared with the rate in 1896. Here is what we believe to be a reliable comparison:—

	R.	c.
Soolai gives an average for 1897	..	3 62
1896	..	3 12
Difference	..	50
Kallunda	1897	4 25
	1896	3 49
Difference	..	76
Muttu Samba	1897	4 36
	1896	3 61
Difference	..	75
Kaivaru	1897	4 38
	1896	3 75
Difference	..	63
Kuruwe	1897	4 12
	1896

This last rice Kuruwe is rather an inferior rice lately brought into country since the Indian Famine took effect. Soolai rice was not seen on the market since April last.

INDIAN PATENTS.

Applications in respect of the undermentioned inventions have been filed, under the provisions of the Inventions and Designs Act of 1888, in the office of the Secretary appointed under that Act during the week ending 29th May 1897:—

Improvements in tea rolling machine tables, to be called "Flockhart's solid reversible well casting and plates for tea leaf rolling machine lower tables."—No. 211 of 1897.—William Burt Flockhart, engineer, Sonajuli tea estate, Tezapore, Assam, for improvements in tea rolling machine tables, to be called "Flockhart's solid reversible well casting and plates for tea leaf rolling machine lower tables."—*Indian and Eastern Engineer.*

RUBBER CULTIVATION IN THE STRAITS.—It is evident that the coming product "rubber" is not to be neglected by planters in countries around us: we have on an enquiry from an ex-Ceylon planter in the Straits for our Manual and for seed, the latter of which we can only answer by referring the applicant to the Manager of Culloden estate.

DRUG REPORT.

(From the *Chemist and Druggist*.)

London, May 27.

Cardamoms show an advance of from 1d to 4d per lb., according to quality. S. Amer. Loxa bark sold cheaply. Croton seed neglected and tending easier. Zanzibar cloves flat. Cochin ginger is dull, Jamaica in large supply and about 2s lower. Nutmegs are firm, but mace is slow of sale. Quillaia-bark is much dearer.

CARDAMOMS.—It is said that the last shipments of the recent crop of cardamoms have now been made from Ceylon, and that there is only about 150 cwt. of the drug left there, the bulk of which will be required for consumption in India. At auction today the supply consisted of 84 boxes only. It was evident that buyers had recovered from the shock of the recent "monster supply," for bidding was very brisk, and prices were higher all round, good to fine qualities being from 3d to 4d, small kinds 1d to 2d per lb., dearer, while for seed an advance was also obtained. About 55 boxes sold as follows:—Ceylon-Mysore, medium to bold fine pale 3s 5d; medium pale 2s 1d to 3s 2d; small 2s 2d to 2s 4d; small to medium fair yellow 2s 3d; very small pale 1s 11d to 2s per lb. Ceylon-Malabar, medium to bold fair but light 2s 6d per lb. Seed, according to quality, from 2s 5d up to 2s 11d per lb.

CINCHONA.—At today's auctions only South American barks were offered. Twenty serons Loxa sold cheaply at 7d to 8d per lb. for fair quality, and at 3½d for ordinary damaged ditto. Twenty-three bales of Bolivian-Callsayan, thin orange pieces, were bought in at 1s per lb. One bale of Red bark, in small thin chips of little colour, at 6s per cwt., and 10 bales fair Carthagena at 6d per lb. Of a new arrival of 58 bales Guayaquil, 2 sold at 7d per lb. for fair, partly mossy, and 4d per lb. for very ordinary dull quality.

CROTON-SEED.—Buyers are holding off, evidently fearing that further supplies will come in. Eight packages were bought in at auction today, fair quality from Bombay at 7s per cwt.

QUININE.—The situation is very uncertain. The Brunswick factory still quotes 9½d nominally, and Howard's only 9d per oz. for bulk, but the makers are very careful to whom they sell, as they do not wish to encourage speculation. The Auerbach factory is not a seller at present, but on Monday B. & S. offered for July-August delivery at 8½d per oz. They have sold several small lots to druggists, but they refuse to deal with brokers and speculators. Among other business which was rejected was one order for 10,000 oz. for shipment to America. Today they are not selling at all. On the spot the market is firm, and it is doubtful if much can be had below 9d per oz., or even at that figure. At auction one case of ten 100-oz. tins of Tallandier's realised 8½d, and a case of twenty 100-oz. tins Dubose 8½d per oz., the last-named figure being subject to approval.

OIL (essential).—For 3 cases fair Cinnamon oil at auction today 1s 5d per oz. is to be submitted.

KOLA-NUTS, 23 packages changed hands at 3d, good dry description.

INDIAN TEA ASSOCIATION AND LABOUR SUPPLY.

A meeting of the Indian Tea Association of London was held on Tuesday, June 4th, at 14, St. Mary Axe, to consider the question of promoting a movement of the Indian population from the congested districts for the purpose of cultivating the waste lands in the Assam Valley. General Hopkinson (late Agent to the Governor-General in Assam) presided, and said he thought it clear that the immense area in Assam could only be cultivated by independent immigration. The first thing to be done towards promoting such a movement was the adoption by the Government of India of the recommendation of the Chief Commissioner of Assam that the Assam-Bengal Railway should be extended from Gowhalty so as to join the Northern Bengal Railway system. Tea planters would be relieved to find that the Chief Commissioner was fully alive to the necessity of adopting precautions to prevent any facilities given for bringing land under cultivation resulting in the enticement of coolies from the tea gardens. He would not himself incur the responsibility of

founding a colony of Bengali coolies in Assam, as he believed the country as a whole to be unfitted for their occupation. The Hon. P. Playfair spoke of the importance of the Indian Government adopting some scheme for transferring agriculturists from the congested districts to the Assam Valley. He thought such a policy would be in the interest of the Assam tea companies, as it would probably relieve them of the necessity of keeping for 12 months coolies who were serviceable for only five or six months in the year. The jute trade of Dundee would also be benefited because the churs in Assam were well adapted for growing jute of a High quality. A discussion followed, and on the motion of Mr. R. B. Magor, seconded by Mr. A. C. Sweeting, it was eventually resolved that as the subject discussed was of such importance, its further consideration should be postponed to a future meeting.

HOW TO RE-INTRODUCE CHINA TEA INTO PUBLIC FAVOUR.

To the Editor of the

NORTH-CHINA DAILY NEWS.

SIR,—I venture to address you on the necessity of employing the sirocco in the manufacture of tea.

To develop malty flavour and good keeping qualities, samples which were characterized by London brokers on arrival as "flat, dull, and wanting in fragrance," were put through a Sirocco, and in each instance were enhanced in value, flavour, and character by quite twopence per pound. It has been demonstrated that a rich malty flavour can be developed upon any teas by proper treatment of them in the Sirocco, even after their arrival in London, but of course the process gives better results if done in the manufacturing districts, than if done after the teas have been kept three or four months in an imperfect condition. It is a great pity when every possible care has been given to the manufacture of the leaf from plucking to packing, that the fullest benefit should not be obtained therefrom, simply because of imperfect performance, which can be easily acquired by firing for the development of flavour, and for giving "good keeping" qualities to the tea. It is in the final siroccoing of the tea before packing that the best flavour is developed, and the apparatus can produce it upon teas which have received their primary drying over charcoal. Careful attention to the process may easily effect a difference of twopence or threepence per lb. in the value of the teas for the London market. Properly siroccoed teas actually improve by a few months' keeping in well closed chests, whereas teas improperly treated before packing "go off" and depreciate before arrival in London, and continually go from bad to worse.

The process is really a roasting more than a drying process for, at a low temperature, the tea could be made perfectly and absolutely dry, without in the slightest degree producing the richness of flavour that a suitably high temperature will develop.

It is the chemical action of hot air upon the tea which produces the rich flavour referred to, and air at about 150 to 220 F., according to elevation, develops it better than at any other temperature.

Pure hot air has a more energetic and perfect chemical action on tea than air which is impregnated with fumes of coke or charcoal fires. It is absolutely necessary that the hot air should get at every leaf properly, so that the tea itself be raised to the requisite temperature; it will not do therefore to hurry the roasting process.

With fine broken teas a less quantity should be put in each tray, because the leaves lie so close that they offer a much greater resistance to the passage of the hot air through the trays than is the case with open leaf, like Pekoe or Souchong.

A very high temperature can be used even up to 300 F., if the teas have been kept a length of time before packing, and have become somewhat flat and soft flavoured, but at this temperature very careful attention is required, together with thin spreading of the tea upon the trays, and quick removal the moment the necessary flavour is attained. If left too long at such a high temperature discoloration of the infused leaf would be the result, whereas at the lower temperature the leaf is scarcely perceptibly darkened in colour, no matter how long it may be subjected to that degree of heat. Too high a temperature is likely to develop a burnt flavour, and discolouration of the infused leaf. The infused leaf of properly roasted tea should be a degree, but only just a perceptible degree, darker in colour than the same tea without being roasted, and the dry leaf should be somewhat more glossy black, and the pekoe tips a shade yellower. A tin-lined bin or box, of suitable dimensions, should be provided alongside the sirocco, and each tray full of tea as finished should be emptied into it. A full day's work of one sirocco ought to fill this bin, say 1,500 lb., and before packing the tea should be well bulked together, otherwise undesirable variations in value may occur, even from the most practical hands. The tea will be found to remain hot enough in the bin to be suitable for bulking and packing in the evening. From ripe experience tea planters in India and Ceylon deem the Sirocco absolutely necessary to satisfactorily cure their yield, and the romance of only rolled tea would quickly disappear if compared with properly machine-made tea which I have carefully tested.

The following are the necessary qualifications:—Withering, rolling, fermenting, drying, sorting and packing.

In conclusion I might remark upon the large quantity of "out of condition" and damaged teas at present offering on this market, some of them entirely unmerchantable, which if properly made by machinery would have been valuable, and saved the owners from the probable heavy loss.—I am, etc.

Hankow, May 27th.

WM. WHITE.

—N.-C. Herald, June 4th.

PRODUCE AND PLANTING.

THE OUTLOOK FOR TEA.—Following the example of those who cry peace when war is inevitable, some people find a subtle pleasure in pointing out danger in anticipation of evil and without sufficient cause. The frequent additions to the list of new tea Companies lends some point to the warning of financial critics who are anxious no doubt to guide investors in the right path at the earliest possible moment, and to exhibit a red light before there is actual danger. This is admirable as an exhibition of alertness, but it is not fair to an industry which has a clean record and, we hope, a bright outlook. The risk of good and bad seasons, the bugbear of over production, are dwelt on with great emphasis. The old, old story is reiterated that new markets must be found, consumption must increase or else dividends will decline. These are truisms, and in emphasising them the writers are merely calling attention to the ordinary risks which attend all commercial ventures. The demand for remunerative investment is so keen that tea-garden proprietors have not unnaturally taken advantage of the moment to convert their estates to the joint stock form. Allowing that tea companies are increasing rapidly, and that when the new land is cultivated and in bearing the supply of tea will also be much larger, the danger apprehended may be minimised by the opening of fresh outlets for the supply and the further development of home consumption. Identical risks attend all forms of enterprise, but we are not aware that quite so much stress is laid on these chances in their application to other industries. The past year has been a prosperous one for tea, and the prospect continues good. The need for scrutiny in the case of some of the new concerns offered to the public does not warrant insinuations against the good faith

of all vendors, nor justify gloomy forebodings of future trouble, unless those who indulge in them think it accords with the fitness of things to cry "Breakers ahead!" when the ship is going steady in mid ocean. There is no sign at present of the downgrade movement which a few pessimists try to discern. On the contrary, the past year's record, as far as it is known, shows that the majority of Indian and Ceylon tea gardens are worked with remarkable ability, and that the industry for the most part is in the hands of capable and straightforward men with sharp eyes to its further progress.

THE CHEMISTRY OF COCOA.—It is desirable that those who handle produce should know something about it, and the *Grocer* therefore gives its readers some information about the chemistry of cocoa, in which it says: "Cocoa is obtained from the tree *Theobroma cacao* and its congeners, several species of which are indigenous to South Africa, and are cultivated in the East and West Indies, parts of Africa, and some districts of Australia. The portion actually utilised is the seeds, some thirty or forty of which are found embedded in the pulp of each cocoa fruit, the latter being a pod about eight to ten inches long. To isolate the seeds the pulpy mass is allowed to ferment for a time; it thus becomes more easily disintegrated, and allows a ready separation of the seeds. The latter are also believed to share in the fermentation process, and according to some authorities the characteristic cocoa-alkaloid is formed during this stage; but whether this be so or not, it is certain that the flavour and aroma depend largely on the careful fermenting and the subsequent drying and roasting to which the cocoa-beans are subjected. After the roasting the husk of the seed is separated, and the resulting kernels are what are known commercially as 'cocoanibs.' They contain a remarkably large proportion of fat or 'cacao-butter,' fully 50 per cent. being usually present. Other notable constituents are albuminoids, about 12 or 14 per cent.; cellulose, 8 or 9 per cent.; starch, 2 or 3 per cent.; and appreciable quantities of sugar, gum, tartaric acid, and 'cocoared,' this last being a colouring matter resulting from the oxidation of the tannin of the cocoa. It is worthy of notice that cocoa contains considerably less tannin than is present in tea. The most important ingredient, however, is the cocoa-alkaloid theobromine; this substance, though only present in the comparatively small proportion of 1 to 4 per cent., is the constituent which chiefly confers upon cocoa its stimulative and refreshing properties. Theobromine is a white powder with a very bitter taste, showing marked poisonous effects when taken in large doses. It is a nitrogenous compound closely allied to the caffeine of coffee and the theine of tea; and like these bodies, it acts physiologically as a stimulus to the heart's action and as an excitant of the nervous system. One curious fact about cocoa is that, like preserved peas and some kinds of oysters, it always contains a small quantity of copper. The proportion, however, is very minute in good-class preparations.

THE MANIPULATION OF COCOA.—"So much for the material which the cocoa manufacturer has to manipulate. But, as mentioned above, it contains about half its weight of 'cacao-butter,' and hence cannot well be ground straight into a powder. Two methods of overcoming this difficulty are in use, one yielding the class of preparation known as 'cocoa essence' or 'extract,' the other giving ordinary cocoa and chocolate. In the first process part of the fat is separated by warming the material and pressing out the melted cacao-butter; in the second method the crushed nibs are 'diluted' with a considerable proportion of sugar and farinaceous substances, of which the principal are arrowroot, rice-starch, and wheat flour. Broadly speaking, all the various brands of cocoa and chocolate fall into one or other of these two groups; the differences mainly consist in the varying quan-

titles of fat extracted, or of sugar and starch added, and in the nature of this last ingredient. Flavouring material, such as vanilla and spices, is used according to the taste of each maker, thus giving rise to minor distinctions. With regard to the 'essence,' the removal of the fat, besides giving facility of manipulation, has the further advantage of rendering them somewhat more easily digestible, too much fat being prejudicial to proper assimilation. Most grocers deal in soap, but it will probably surprise them to learn that they may be selling a notable quantity of that detergent whenever they hand over the counter a pound of cocoa to a customer. Yet it is a fact that some kinds of cocoa do contain quite appreciable amounts of soap. It is not added as an adulterant, but arises thus: The fat which remains even in the cocoa essences is sufficient to give visibly oily drops on the surface of the liquid when the beverage is prepared. To prevent this unappetising appearance the cocoa in some cases is treated with alkali, which combines with the fat-acids to form a soap. The latter dissolves in the hot water, and so does not show on the surface as the oily globules would.

A COMPARISON WITH TEA.—"Cocoa is correctly recognised," according to the *Grocer*, "as being more nutritious than tea, but no doubt the great difference in the 'thickness' of the two beverages tends to unduly exaggerate this idea. It should be remembered, however, that the greater density of cocoa-emulsion is mainly due to starch, sugar, and fat, which are all heat-producers. The percentage of albuminoids in cocoa powder is really but little higher than in tea. Of course for each cup of beverage drunk a larger quantity of cocoa is taken into the system than is the case with tea, and therefore a greater amount of albuminoids; but, on the other hand, something like 30 or 40 per cent. of the total nitrogenous food present in cocoa is quite indigestible. The cacao-butter expressed from the nibs is a valuable by-product much used for pharmaceutical preparations and the more expensive kinds of soap. In Germany the husk themselves are used to prepare a beverage, 'cocoa tea,' which is an infusion of the husks made and drunk like ordinary tea.—*H. & C. Mail*, June 4

A NEW PATENT TEA BULKING AND BLENDING MACHINE.

We hear that a well-known Manager has just invented what is described as a splendid Bulking and Blending Machine. The invention came about in this way:—

"On receipt of a circular from home lately to the effect that all bulking was to be done under European supervision, and not being provided with the bronchial tubes of the elephant, and being of a decidedly asthmatical temperament, I was—after being nearly choked with fluff—compelled of necessity to invent a machine which you will be glad to hear is, so far, a decided success, thus adding another proof in support of our creed of 'pure machine-made Ceylon Tea.' When one sees the teamaker changing the bulking coolies owing to the perspiration breaking out even on them, and you begin to wheeze like the steam chest of an engine, it is time, I say, to think about inventing a machine, and I think I have got the very thing we want now, and when completed it will be a bulking, blending, final firing, and packing machine. The 'Vortex,' with the help of a little elevator to raise the tea, will most effectually bulk 7,000lb. and 8,000lb. per hour. I was so pleased with it the other day, I felt myself singing:—

No more inhaling of fluff
No bathing in perspiration,
The Dorey is always up to snuff,
Give him beer and good respiration."

COST OF LIVING FOR A PLANTER ON A SOUTH INDIA PLANTATION.

I have been greatly interested in several letters in the last few numbers of the "P. O." from planters, giving statements of their monthly expenses. "Ex-Creeper" seems to have lived in an exceedingly cheap district, and I congratulate him on his economical living though I am afraid I cannot do the same to "Indigo Assistant." The following is a statement of my actual necessary monthly expenditure, and I think it is a fair statement of the usual expenses of superintendents in my district:—

Some may consider a chokra an unnecessary servant and under ordinary circumstances, I think, he is, but I happen to live in a district when there are a number of neighbours, and thereby having many visitors, I find a chokra indispensable. Bazaar account includes fresh mutton (twice a week), fowls, vegetables, sugar and salt for cooking purposes, bread and oil. My present income is, I may state, only just over R100 per mensem. The balance goes to club subscription, medicines, bungalow and toilet necessities, clothes, boots, stationary, &c. A young planter can live comfortably on R100 per mensem, but on less it is only existence. I quite agree with "Indian Planter" that planters are very badly paid (as a rule). My life as a planter is a very pleasant one, and I should not like to change it; at the same time, under present circumstances, I am really only vegetating. How is a man to save say even £100: or at least how long will it take him to save it, on R100 or R83 a month? "Home" seems a long way off, does it not? And prospects look very black at present. However, let us hope that next year crops will improve, and that the prospects and pay of superintendents will likewise improve.—Yours faithfully, A COFFEE PLANTER.

—*Planting Opinion*, June 12.

THE MADRAS AGRICULTURAL CHEMIST.—Says the *Madras Mail*, there is a concise and workmanlike abstract about the Report of the Agricultural Chemist for the year 1896-97 which shows that Dr. Walter Leather has not during his few years of office been much affected by Indian Secretariat notions of what such documents should be like. It covers only eight pages of print, yet it contains an excellent summary of his year's work and some very lucid comments on various points of importance. His five tours during the year were chiefly occupied in the inspection of Agricultural classes and the investigation of sugar-cane cultivation in different parts of India. His time at headquarters was chiefly spent in conducting analyses and answering references for advice from many quarters. The chemical examination of Indian soils was also pushed on during the year and is now approaching completion. The enquiry comprises about 80 different varieties supplied by Local Government and will be of the highest importance when finished. At the same time it cannot, as Dr. Leather remarks, be considered to deal exhaustively with the soils of an Empire so large as India: indeed the object aimed at is merely to show the chemical composition of some of the main types of Indian soils. Dr. Leather quotes as an example illustrating the value of chemical analysis in relation to soils the details of an examination of three samples from one of the Dehra Dun Forests which clearly proved why young growth flourished well in some places and not at all in others. On the other hand, he quotes examples showing that the value of mere analysis limited and that the conditions of climate, the lie of the land, its water-supply and drainage form most important factors.

Correspondence.

To the Editor.

"ACACIA DECURRENS"—NOTES BY A PRACTICAL PLANTER.

AN AMBAWELA FUEL AND BARK COMPANY
ADVOCATED.

Albion, Nuwara Eliya, June 5th.

DEAR SIR,—Your correspondent "T." [see page 57 of July T.A.] evidently lost all interest in *Acacia decurrens* after the collapse he refers to, but will he be good enough to explain what he means by "decurrent"? Some local would-be authorities argue that the term has reference to the habit of certain of the acacia family of *running* or spreading from the roots (notably *A. melanoxylon* and *A. dealbata*); but with me *Acacia decurrens* does not throw up suckers, even when the roots are cut. "T" asserts there are over 70 varieties of *A. decurrens* but in "Wattles and Wattle barks" by J. H. Maiden, F.L.S., T.C.S., &c., Curator of the Technological Museum, Sydney, 1891, there are only five varieties mentioned which you will find fully described on pp. 69-70: *decurrent* here refers to "angles from the base of leaf stalks."

Your correspondent's experience with bark was certainly not encouraging, but what would he say to R140 per ton in Colombo? I have an order now on hand at this rate. The boiling-down process you advocate is described on p. 26 and you will note that "trash" (*i.e.* prunings and branches) is chiefly dealt with in this way. "T"'s experience with mixed seed is not unique, see what Maiden says on the subject on page 7: locally produced seed is not open to this objection, my seed-bearers being all of the same variety. The information on pp. 66-69 would be interesting to intending planters, as also the "Bamboo method of planting" described on page 10. The reed *Arundo Donax* referred to, grows here freely, and when once established, will give an annual cutting of stalks from 12 to 20 feet long; besides being useful for plant raising, they make very neat temporary fences, warrachies for lines or split up into pegs for lining.

Who will start the first Fuel and Bark Company to buy or lease a few thousand acres of the now unproductive patana land along the Railway line between Nannoya and Ambawela, in order to supply tea estates with fuel, the world with tanning substances, and in six or seven years give the shareholders cent per cent on their outlay!—Yours faithfully,

A. J. KELLOW.

MR. GREEN APPOINTED HONORARY GOVERNMENT ENTOMOLOGIST.

Planters' Association of Ceylon,

Kandy, 9th June 1897.

SIR,—In continuation of previous correspondence published regarding the appointment of a Government Entomologist, I enclose copy of a further letter received from Government.—I am sir, yours faithfully,

A. PHILIP, Secretary.

Colonial Secretary's Office, Colombo, 8th June, 1897.

Sir,—I am directed to acknowledge the receipt of your letter of 28th, May, and to inform you that the Government are willing to purchase 12 additional

copies of Mr. Green's book on the "Coccidæ of Ceylon," for distribution among the Kachecheris in the planting districts.

2. I am at the same time to acquaint you that His Excellency the Governor has been pleased to appoint Mr. Green, to be Honorary Government Entomologist.—I am sir, your obedient servant,

(Signed) H. L. CRAWFORD,
for Colonial Secretary.

The Secretary, Planters Association of Ceylon.

THE DISEASE AFFECTING CACAO TREES: MR. J. R. MARTIN IN EXPLANATION.

Yattewatte, Matale, June 13.

DEAR SIR,—I was glad to see [*vide* page 106] a correspondent writing with a view to adding to our knowledge of cacao disease. In my letter of the 6th inst. to the "Times of Ceylon," I merely gave my own opinion. I have no wish to dogmatize on this subject, and the fact of your correspondent disagreeing with my views, shows the value of discussion. We agree however on two points;—1st that this disease is not a root disease, and secondly that it is the work of a *Poochie*. Your correspondent is also certain that if a diseased tree is cut down the sucker which grows from the stump grows into a healthy tree. This is most valuable information. So on these three points something has been learnt.

As it seems to be assumed that I am opposed to the scientific investigation of this disease, I wish to explain that the idea of getting out a scientist originated with me. On the 13th February last I called on Mr. Dickenson of Warriapolla to discuss the disease, and we then agreed to raise at once such a sum as would bring out a competent man without delay. I have no doubt that the necessary funds would have been at once forthcoming. Afterwards Mr. Dickenson without consulting me wrote to Mr. Christie and asked for Government help, and Mr. Christie at once applied to the Governor—against this I protested as soon as I knew of it. Firstly, because I thought it highly probable that if we trusted to Government for a man, we would have to wait a long time for him, and secondly, as I wrote to Mr. Christie, because as soon as it is known, that we have asked for Government help, alarmist paragraphs will appear in the papers, and the financial position of cacao will be severely injured. Mr. Christie made light of my objection; but here we are with no immediate prospect of scientific help, and I think both my anticipations have been fulfilled.

At the same time I think it is probable that if cacao planters had taken up the matter for themselves and made inquiries at home in the right places, that we would have had a man on his way out now.

Sir West Ridgeway acted with zeal and promptitude when the matter was brought before him, and as matters stand we must wait on Government for help, but I think when the matter was put into Government hands, it was a foregone conclusion that there would be a great deal of delay. The authorities at home are not likely to keep a reserve of scientists ready for dispatch to distant Colonies, and as the responsibility now rests with them, they are sure to act with slowness and caution.—Faithfully yours,

JAS. R. MARTIN.

THE DISEASE IN CACAO: PRACTICAL HINTS.

DEAR SIR—I see from the papers there is a great deal being written about a new cacao pest (a weevil) we are said to suffer from on some estates and in some districts more than in others. I think all men interested in cacao planting should have your *Tropical Agriculturist* volume for 1884 and 1885 wherein cacao planting and pests are well discussed. See proceedings of Planters' Meeting folio 90, 91, 92 and 93. Dr. Trimen's letters folio 110 and 328. Advice to young cacao planters 333, 385 and 478 and many more letters as per Index. Dr. Trimen goes fully into insect pest in his valuable letter on folio 328, even the best of doctors or scientists differ. Dr. Trimen says on folio 111 flat ground is better than sloping for cacao; Bosingault says on folio 222 cacao grows best on a gentle slope;—Mr. Vollar says on folio 90 on one estate badly affected the land is poor and soil shallow; Mr. Jardine says on folio 92 poverty of soil has nothing to with the pest, he had some of his best cacao affected.

INSECTS.—The smaller the insects the larger the swarms they travel in for mutual protection. They as a rule never stay long in one place, as with the bee, helopeltis, paddy fly, weevil or tomici—so any visitation from these insect pests is only temporary. Strong remedies I have always found, that destroy the pest, also injure your trees. The use of woodash, lime and cowdung to the branches or stems which these insects do not like, used properly, prevent such insect attacks and are actually a manure for the tree, especially so when washed off, to the roots around the tree. The insects will soon find they are on forbidden ground and then swarm and go off some night to pastures new. I recommended in 1884 croton oil trees for shade or wind belts. Some planters who planted and kept up their croton were glad enough, to get their 60/ to 80/ per cwt. for the seed last and this year.

WIND.—You can stop the wind injuring cacao, &c., by planting useful belts, from which a profit can be made.

POOR SOIL.—We certainly have a variety of soil in Ceylon and it requires some time to understand the wants in different soils for the plants—from the growing plant you can often make out what is different in the soil, otherwise by filtration of soil. I have no difficulty now to provide the necessary nourishment and bring my plants up to an evenness all round, same as I did on Maria estate with the coffee (flat and steep land, loamy and quartz soil) yet coffee trees as well as crop, when His Excellency Sir John Douglas visited the estate, were all that could be desired. So can cacao be worked up to pay now.—Yours faithfully,

JOSEPH HOLLOWAY.

CACAO DISEASE.

Greenwood, June 17.

SIR,—I wish to submit a few remarks with reference to the two letters of Mr. Jas. R. Martin lately published by you.

He writes: "I can assure you, that the acreage which has suffered at all, is a small percentage" and further "Another point is that, whilst the acreage of cacao is, if anything, diminishing, (why?) the export of cacao is steadily increasing."—This has no value as argument against the virulence of the disease, for the high prices ruling for Ceylon Criollo up to the beginning of 1894, induced a large extension in the cultivation with more robust kinds which coming gradually into bearing makes more than up for the yearly mortality, besides, the trees are said to increase their bearing power up to the 10th year and it is only 20 years ago that planting began in this Island.

What has to be considered to make out if a product is remunerative or not is the acreage in

bearing and the value of crop and I maintain that if the numerous native gardens were taken into account and the large acreage which has been abandoned between 1835-1890 owing to the then prevailing disease, it would be found that its cultivation is unremunerative in Ceylon, giving now an acreage return of less than, so far, *two cwt. per acre!* and only double this amount under very favourable conditions.

He admits the possibility that the red cacao of Ceylon (commonly called Criollo) will be entirely superseded by Forastero and by this he gives himself much more away in trying to prove the innocuousness of the disease than the unfortunate who saw 50 or 25 per cent. of his trees die out, did as a planter. This stricture of Mr. Martin was not charitable.

If then all the Criollo is likely to succumb "although gradually and thereby not bringing on a crisis," nevertheless will there be a greater loss than with coffee being replaced by tea, both products giving a return after 3 years when cacao takes double the time; and besides the success of supplies is by no means so general as Mr. Martin states, which is always the case with products of the same family.

What you so justly said in your article on the "Cacao Pest" (see page 801, *T.A.* for May)—"Through some occult reason the subject was tabooed in public; most people seemed to know of it and yet it was never discussed" . . . "Has this conspiracy of silence been wise?" Mr. Martin clearly thinks so, for he writes:—" . . . as soon as it is known that we have asked for Government help, alarmist paragraphs will appear in the papers, and the financial position of cacao will be severely injured." In what way?—In the fictitious value of property falling to its level, is the only and not very sound nor moral one I can see.

I agree with Mr. Martin that the author of the destruction is a *pouchie* (*Tomicus perforans*) brought by me to your notice in November '94 for the first time, but my impression is that, so far, observations of it have been superficial. Now that the Honorary Entomologist and the Director of Botanical Gardens are at work, I suppose we shall, in time, have a proper monograph of the insect and its metamorphosis and the effects of its working.

It is my opinion that, as with Phylloxera, black and green bug and *hemiteia vastatrix*, no efficient *prophylactic* remedy (the only one effective) will be discovered without the cost of application being prohibitive and therefore the best course is to plant the Criollo fields with one of the good hardy varieties, which so far have been unaffected.

Pioneers, as a rule, fail: those in the cultivation of cacao in Ceylon have followed this rule and the cause of it is, that in their ignorance they have planted a species of cacao, the only one then existing in the island, which proved later on to be very liable to disease, and similar, probably, to that which died out in several parts of the West Indies. The higher prices obtained for it encouraged them for some time to persevere in the mistake, till some of the more hardy kinds, latterly imported, having come to a certain age, shewed their resistance to disease and are still free from the attack of *Tomicus*, but there is only proof of comparative immunity where other varieties in close vicinity are attacked.

I know of two Venezuelan kinds which have stood this test and besides being very robust bear a good size pod with thin rind and large

beans, cream or light purple inside. They are far superior to the true Forastero, with flat beans, dark purple inside, flinty when dry, and always quoted in Europe below the other kinds. Some of the varieties of the Peradeniya Gardens are very robust, but the bean belongs to the latter type.—Probably other good varieties exist in the island, but I think that the selection of the best seed cannot be too much recommended.—Yours truly,
A. VAN DER POORTEN.

MR. E. E. GREEN ON THE CACAO DISEASE
—AND WITH PRACTICAL
INFORMATION.

Eton, Punduloya, June 21, 1897.

DEAR SIR,—Mr. Joseph Holloway's letter (see page 124) refers sufferers from the present cacao disease to the discussions on cacao pests in the *T.A.*, 1884-85. The present circumstances are however, very different. The disease of that day was traceable to *Helopeltis* and took the form of blackened shoots and branchlets, with subsequent dying back of the branchos. This trouble is still present to a certain extent and may possibly be confused with the more serious disease which is now attracting public attention. In the present cases investigations on the spot lead me to believe that, the disease is *not directly traceable to any insect*. It commences with the bark, and when the canker has completely girdled the stem or limb, then—and not till then—do the upper parts of the tree die off. One special character by which this disease may be recognized is a claret-colored stain which is visible upon cutting into the affected parts.

There is however, one reference to the same or a very similar disease in this volume of the *T.A.* ('84-85). On p. 114 there is a quotation from an earlier *Tropical Agriculturist* published in 1833 by G. R. Porter. After describing various enemies of the cacao the article goes on to say.—“Cacao trees are likewise subject to a disease, which shows itself in the form of black spots, or blotches, on the bark, and which, as soon as they appear, should be carefully cut out, or the trees will quickly die. This disease does not make its appearance until the trees are in a bearing state.” It is not quite clear from what country the disease was they described; but from the incidental mention of “Spanish planters” it is presumably referable to one of the Spanish colonies. It seems at any rate that the disease is an old one, and further information may perhaps be obtainable from the same source.

With reference to the present day *Tropical Agriculturist*, this most useful publication would be still more valuable for every day reference if a general index of say the first 10 volumes was available. It is a work of considerable time to search through the numerous volumes for information on any particular subject.—Yours truly,
E. ERNEST GREEN.

CACAO CULTIVATION IN CEYLON—THE
CROPS, VALUE AND DISEASES OF
THE PLANT.

Yattewatta, Matale, June 24.

DEAR SIR,—As far as I can follow Mr. Van Der Poorten's letter to you, (see above) the points he raises are:—

1. That to arrive at the present position of cacao, a comparison of the yield per acre with that of a few years ago should be made,

2. That two cwt. of cacao per acre does not pay.
3. That he is so far convinced of the ultimate success of the stronger kinds of cacao generally, known as Forastero, that he recommends his brother planters to plant them.

To No. 1 the answer is easy:—in the Report of the Planters' Association of 1894, I think, the acreage planted with cacao is given at 18,000 acres and the acreage in bearing 12,000 acres, the yield per acre is cwt. 2½ per acre. It is a liberal estimate to say that 15,000 acres are now in bearing, 14,000 is probably nearer the mark, and the estimated crop is cwt. 35,000; so the yield per acre has not fallen off.

In answer to 2, the acreage value of cacao for the year is probably 68s per cwt. in London. Values in cacao generally fall at this time of year, and it is now quoted at 65s, which means a net in London of 57s—say 55s—to be on the right side, and cwt 2 are worth £5 10s; against expenditure, say, the equivalent of £3; profit £2 10s per acre, which, on a capital account of £20 per acre (a most liberal allowance for bringing cacao into bearing), means 12½ per cent. That is what cacao means giving bad crops and getting bad prices, and allowing an outside figure for capital account. But I have shown that the crop for the whole island exceeds cwt 2 per acre, so that it must be a very bad estate that does not give something more than this. Take cwt 3 per acre as the yield of a fairly good estate and it will be seen that even in these bad times there are worse things than cacao.

The third point. I cordially endorse, and for many years have had the courage of my opinions. I have, with a few exceptions, planted with stronger varieties of cacao generally known as Forastero for the last ten years and am now reaping the benefit of having done so.—Faithfully yours,
JAS. R. MARTIN.

CACAO CULTIVATION AND PRICES.

DEAR SIR,—With reference to Mr. Jas. R. Martin's letter I wish to submit a few remarks. The price of 65s which he adopts is far above the mark, that being the telegraphic quotation for *fair red bold*. What about the dark, the triage, the native, the broken? Would the price of good broken pekoe be accepted as the average price of tea?

If the £20 to bring cacao into bearing includes the price of land, I think it decidedly cheap.

I take exception as to the acreage; for Mr. Martin has left out of calculation the native gardens which must produce several thousands of cwts.

My contention is that so far, cacao has not been a profitable product in the island; that is if all the failures are set against all the returns; in other words if a proper debit and credit account based on proper statistics, is established.

It is obvious too that even an average return of 2 cwts. per acre must indicate that cacao has not found a suitable habitat in Ceylon.*—Yours faithfully,
A. VAN DER POORTEN.

TEA BULKING: PRACTICAL ADVICE.

DEAR SIR,—As the subject of tea bulking is much in evidence at present, and perhaps justly so, a few remarks on it may not be altogether amiss.

* That is in certain parts; for there are plantations that yield a good deal more and are decidedly profitable as Mr. Martin reports his own experience to be.—Ed. *T.A.*

In the early days of the Tea Industry here, a high authority stated in the *Observer* that the way to bulk tea was to put it in a heap from the bins, then spread it out in a circle, then heap up again and so on till a perfect equalization was obtained. This is a slovenly plan, as the coolies would be kneeling or squatting amongst the tea.

In absence of a bulking cylinder, a neat and sure way is to operate on a floor 30 or 40 feet in length by 10 feet in breadth, the tea brought from the bins in pails or bags, then poured out shoulder high, from end to end of the space above mentioned. All bins containing the grade should be opened simultaneously, and the charges of pails or bags poured out alternately from the several bins. When finished the heap of tea will be at an angle, like road metal, several feet in width at the base.

The tea of various fields, and days' makes, will now be in *strata* in the heap; all that is required is to turn it carefully from end to end twice. The further handling of the tea in final firing and packing will thoroughly mix it, all differences will be incorporated, or bulked. This work is soon learnt by coolies, and is done very speedily and costs little or nothing; but it is so very important for both buyer and seller, by samples, that the Superintendent should see it done. Should he choke with the tea bloom, no matter. It is easy to close up the ranks!—Yours faithfully,

“SENEX.”

TEA PREPARATION IN INDIA.

SIR,—Can any of your planting correspondent kindly enlighten me on the following point:—

We find that if we wither our leaf on these estates according to the average wither, we get a dark out-turn, and consequently we have to put up with an undue proportion of broken leaf owing to the wither being light, in order to obtain a bright out-turn.

If any of your planting friends would kindly suggest any method that would enable me to obtain a good wither without a dark out-turn, I would be very thankful, also I would be interested to hear whether this local peculiarity has been observed elsewhere.—Yours faithfully,

AN INDIAN PLANTER.

P.S.—Leaf I have obtained from out-lying localities, I find I can wither well and run no risk of dark “out-turns.”

[Reference to an experienced Ceylon Manager has brought us the following:—

“It is impossible to express an opinion on enclosed as there is no reason why the leaf from out-lying localities should differ from his local leaf if the conditions are similar in both cases, and the treatment of the leaf identical. Given similar jāt, elevation and length of time from pruning, and the results should be the same; but if any of these differ, it might affect the outturn, and in any case he would not get a bright outturn from recently pruned tea. I presume he has tried various experiments with the view of getting the best possible results, but if not, he would better do so. I would wither fully in any case, and if he rolls hard or long, say two or three separate half hours, I would not ferment at all or very little. The roll should not be allowed to get overheated during rolling. I cannot suggest anything else except that I would send my local leaf round by the outlying localities rather than be done, but this latter is really absurd nonsense.”

—ED. T.A.]

CEYLON TEA IN AMERICA: IMPORTANT NEWS FOR CEYLON PLANTERS.

LONDON, June 11.

DEAR SIR.—The threatened duty has not been put on tea in the States. But the new regulation regarding dusty broken teas has already shut out quantities of our teas. These have been refused admittance at the Port of New York. We have repeatedly advertised that our teas have never been condemned at any Port in America. We can boast so no longer. Another blow to broken pekoes—already at a discount. Ceylon planters should copy Indian in making whole leaf (broken ?) pekoes, and less *smashed-up fannings*. For American shipments, it is now necessary “brokens” be sifted out.—Yours faithfully,
WM. MACKENZIE.

13, Rood Lane, London, 9th June 1897 E.C.
WM. MACKENZIE Esq., London.

DEAR MR. MACKENZIE,—We understand from our conversation of yesterday, that all teas entering the United States are now subjected to a sieve test, and that no tea is admitted which contains more than 10 per cent. of small broken.

We therefore think this a suitable opportunity to call the attention of planters to the very large amount of Ceylon tea which is of a nondescript kind, and sorted into no very distinct grade. So much tea marked broken pekoe is neither a true broken pekoe nor a leaf tea, but a mixture of pekoe, broken pekoe, and fannings.

The large quantity of this (which is quite unsuitable for the export trade) coming to the London market has severely depressed quotations for broken pekoes during the past season. The variation in price between them and the pekoe grades is now very small, although intrinsically, for liquor, the difference should be much greater.

We feel sure that if you called attention to this matter on the other side, and pointed out to the planters the necessity for sending home their teas better sorted, that it would be greatly to their benefit, and relieve this market of the super-abundance of so called broken pekoes which has lately been so noticeable. Trusting the above remarks may be of some use.—We are, dear Mr. MACKENZIE, yours faithfully,
GOW, WILSON & STANTON.

A PRIZE OF \$200.

Is offered for the best poem, not exceeding twenty lines on machine made

CEYLON AND INDIA TEA.

Only one prize is offered, but poems found suitable will be purchased from competitors. This method is considered more likely to give satisfaction than a long list of graded awards.

Poems may be signed with name or *nom de plume* for identification and must be sent by *Mail only* previous to Aug. 1, 1897, addressed “Ceylon and India Tea Prize Poem” care of J. Walter Thompson Co., Times Building, New York.

No MSS. will be returned. The award will be made by three literary people and announced before Oct 1st, and the poems published in leading papers.

The following figures or metaphors on the Union of Boiling water with India and Ceylon Tea, must be included in the poem.

1.—A Teaspoon of Ceylon and India Tea is like a maiden's heart, pure and unsullied.

2.—The boiling water represents the man. The warmth of his love extracts and sets free the strength and sweetness of the maiden's heart and thus assimilates all her goodness and purity. The water must be boiling (carry on the metaphor) or the true essence is not extracted.

3.—The Teapot is the altar where the marriage ceremony is performed; in other words five minutes infusion or ceremony make the two into one life.

4.—The liquid tea is the married life, free from bitterness, wholesome, refreshing, and two in one, goes forth doing good to all: soothing, comforting, and invigorating.

5.—Sugar and cream are alike riches and luxury. To many, life is incomplete without them though some think that they spoil its fragrance.

6.—All other teas being soiled by the touch of many unclean hands, (here metaphor) can only make unhappy unions resulting in nerve disturbance and repulsion.

PLANTING NOTES.

COFFEE SHADE TREES.—Sun-dried *Erythrina Lithosperma* loppings, etc., contain per ton:—61.50 lb. Nitrogen; 57.38 lb. Potash; 14.92 lb. Lime; 13.68 lb. Phosphoric Acid.—*Planting Opinion*, July 10.

COFFEE: COST OF HIGH CULTIVATION.—While high cultivation is eminently desirable, it is also extremely costly. We have been told of a certain Nilgiri estate that spends over R300 an acre in cultivation and manuring, and finds it so profitable that even these rates are likely to be exceeded.—*Ibid.*

MR. PATRICK GEDDES'S PICTURE OF WHAT MIGHT BE DONE IN CYPRUS, in the *June Contemporary* is well worth reading. Mr. Geddes, who has been trying to provide for Armenian refugees in Cyprus, shows in glowing periods how a little trouble and skill would open the springs choked by calcareous deposits, restore the dying silkworms, make the island a garden, and establish a school of colonial management whose lessons would be of value throughout the empire.

JAPANESE BAMBOO.—Bamboo and bamboo wares constitute an important item in the miscellaneous export commerce of Japan. Bamboo for shipment abroad is grown in districts adjoining Kyoto and Osaka, and in Shikoku, and in Kyushiu, the varieties differing somewhat, according to localities. In Hiroshima the black and the spotted varieties grow; the former is produced in Kochi, also in many parts of Kyushiu.—*Indian and Eastern Engineer*, June 12.

WOOD FLOUR.—Messrs. Esdail & Co., Ltd., of City Saw Mills, Wenlock Road, London, N., have obtained from the Central Cyclone Company, Ltd., the monopoly for grinding sawdust and waste wood products for the manufacture of wood flour. This material is very extensively used in the manufacture of linoleum, floorcloth, dynamite, &c. Thousands of tons are sold annually, reduced by the pulverizers of the abovementioned company.—*British Trade Journal*, June 1.

LOEFFLER'S BACILLUS IN SAMOA.—In 1896 a firm at Samoa, in the Pacific, imported a supply of Professor Loeffler's "mice-typhoid-bacillus," with which to exterminate rats on the coconut plantations. Rats, mice, and flying-foxes (*Pteropus Samoensis*) were inoculated with no very certain results, except in the case of the flying-foxes; but after a time an extraordinary epidemic of ebrieken-eholera arose among domestic fowls, and dogs also died in great numbers. It has not been ascertained for certain, however, whether these facts were due to the "mice-typhoid-bacillus" or to the unprecedentedly hot and dry weather.—*Chemist and Druggist*, June 5.

TWO TEASPOONFULS OF QUININE were taken by a woman recently. A fit followed, and it required the close attention of a doctor for several days before she was quite out of danger. The case is reported in the *Lancet*, page 1232, and we mention it as one of the results of cheap quinine, as it was worth 6d. she took. In the old days 6d. worth would have done her no harm.—*Chemist and Druggist*, June 5.

COCONUT CROPPING NORTH OF CHILAW.—The Rajakadaluwa district continues to show its fitness as a rich coconut-producing district, wherever due care is taken in cultivation. We have the following return for a typical garden of about 160 acres of palms:—

"Last picking aggregated about 37,000 good nuts, making total for the 12 months 107,000 against an estimate of 65,000. Very satisfactory this for a plantation of 8 to 8½ years and proprietors are to be congratulated. How does this yield compare with that of Kandongamuwa?"

COFFEE NOW AND IN DAYS OF OLD.—A retired Ceylon merchant writes with reference to our remarks on the change which has come over Coffee:—"I agree with you in all you write about coffee. Before Free Trade between the thirties and forties, Jamaica chiefly and Berbice with a small addition to Mocha supplied the whole of the coffee consumed in Great Britain. There was some little Ceylon native also home called "Elephant troil" unpicked full of blacks and almost triage. Duties were then differential."—"Elephant troil" as a term applied to native coffee, is new to us.

JAVA CINCHONA.—The annual report of the Planting Company "Pondok Gedeh" of Java, for 1896, which has just been published, shows that the year has been a good one for the concern. The ordinary shareholders will receive a dividend of 7 per cent. (the distribution for 1895 was 4 per cent.), and a larger sum is carried forward than in the foregoing year. With regard to cinchona, which, (next to tea and coffee) is the principal product of the company's land, it is said that the net profit on that culture was 16,304 f. (about 1,360l.). There are still about 200,000 trees left on the company's plantation.—*Chemist and Druggist*, June 5.

PRICE'S PATENT CANDLE COMPANY (LIMITED) attained its Jubilee on Saturday last, May 29, and we read in a home paper of its interesting connection with Ceylon as follows:—

On May 29, 1847, it acquired, for 250,000l., the business of Edward Price & Co., which had been established in 1830 by Mr. William Wilson and his partner, Mr. Lancaster. That business was formed for the purpose of working an acquired patent for the separation of coconut oil into its solid and liquid constituents, with a view of utilising the former, coconut stearine, as a substitute for tallow, and the latter, coconut oleine, as a lamp-oil. In consequence of the difficulty of obtaining regular supplies of coconut oil, Edward Price & Co. established first a branch house in Ceylon for the purchase of the oil, and ultimately steam-mills for crushing coconuts, in order to extract the oil as the new material for their London works. More capital being required for their operations in Ceylon for other purposes, Mr. Lancaster sold his share to three capitalists—Messrs. Cockerell, Brownrigg, and Larpent, and with these as sleeping partners, with the addition of Mr. Brice Pearce, in 1845, Mr. Wilson continued to carry on the business until it was acquired by Price's Patent Candle Company (Limited) in 1847. Mr. William Wilson became the first chairman of the new company, and his two sons managing directors. One of these, Mr. George F. Wilson, F.R.S., is still a director of the company. The company have published a very interesting memoir of their fifty years' history, beautifully illustrated by reproduced photographs.

THE REVOLUTION IN TREE PLANTING.

(From the "Mildura Cultivator," United States.)

About eight years ago it was announced by Mr. H. M. Stringfellow, a Texas orchardist of large experience, that the theory and practice of tree planting, as handed down from time immemorial, were wrong, and that instead of a tree being the better for having numerous roots when reset, the very opposite was true. Mr. Stringfellow then gave a full history of how he happened to hit upon this truth as well as a detailed account of various experiments upon a great many kinds of fruit and shade trees that seemed to demonstrate the truth of his statement. The statement did not at that time meet with much support, so absurd did the idea of cutting off all the roots of a tree seem to even the most prominent horticulturists. Mr. Stringfellow, however, "stuck to his guns," and in a recent issue of the *Texas Farm and Rancho* he again dealt with the subject, and at the same time he gave the experience of other horticulturists in support of his contention. The article is reproduced below for the consideration of our readers:—

"Though I have written to quite a number all over the country, the invariable answer has been, 'while such treatment may succeed with you, it would be out of the question here.' The fact is we inherit our opinions and ideas, just as well as the peculiarities of our bodies and so true is this that the contrary of their beliefs is positively unthinkable to many men. An instance of this came to me in a letter from one of our most progressive nurserymen. He writes: 'I have been practicing close root-pruning with perfect success for some years, and yet my father, who is 70 years old, and sees the good results every year, won't admit them, but persists in saying that "if the roots were not necessary they wouldn't be put there."' So firmly indeed has this long root fallacy become embedded in the human mind by ages of practice, that even a man of Charles Downing's eminence in horticulture declares in his great work that the 'ideal transplanting' would be to take up a tree with its roots entire. That this would be absolutely the very worst form, anyone can easily demonstrate for himself. Let him take, for instance, two peach or other tree seeds, and plant a few inches apart in, say, a ten inch pot of good rich soil. At the end of next year let him take them out and carefully shake off all the soil from their roots and plant side by side in the open ground. Let him spread out in a large hole all the roots of one tree according to the inherited regulation method, and cut back all roots on the other to about one inch, and the top to one foot—just enough to allow of its being stuck down about six inches, like a cutting. Treat alike, and in two years the root-pruned tree will be many times larger than the other. And here I wish to say, very particularly, that the great superiority of close root pruning is not always so apparent the first year, the tree giving more attention to striking deep roots than to making top. Even for several years, we all know, trees as ordinarily set do well, but this is due to the fact that a large amount of root is removed even then.

"But a comparison with these will prove that when the strain of fruit bearing comes, the close pruned tree—with its roots deep and strong, out of reach of the plough, winter's cold and summer's heat and drought—will stand up for many years, giving good crops long after the other, with its lateral and surface system, has broken down and died. How else are we to account for the early decadence of our latter day orchards? The planter in his haste for fruit demands big trees with plenty of roots and top, to support which, and to make them live, the nurserymen often transplants several times. This gives a mass of fibrous roots, which will undoubtedly—if the season is good—make the trees live, but practically dwarfs them and destroys their future usefulness. While Samson lost his strength through having his hair cut off, a tree is for ever weakened by leaving its 'hair' roots on when set, for it seems then compelled to re-establish itself by emitting new fibrous roots entirely from these. This results in a permanent lateral and surface system. Sink a spade around such a tree a year—or even two—after planting, and a slight pull will lift it from the ground;

a short root-pruned tree will resist any effort. The whole theory of the latter method is simply copying Nature. She starts her tree from seed, with neither tops nor roots, and universal experience has shown that these and trees grown from cuttings (which are practically seed) if never moved, are the strongest, healthiest, longest lived and most productive.

"The advantages I claim for this method—over the all-important one of giving better trees—are: First,

"AN ENORMOUS SAVING

to the nurseryman in digging his stock which now must be taken up with roots a foot or more long. Second, an equally great saving in packing. Instead of great bales of tops, roots, moss, bagging and rope, and labour of putting up the same, or large boxes containing thousands of pounds of the same useless dead weight, a thousand root and top pruned trees could be packed in a medium-sized, tight, box, with a layer of wet moss in the bottom to maintain a moist atmosphere, and shipped with perfect safety around the world.

"THE SAVING TO THE BUYER

will be even greater. As an instance, several years ago I ordered 5,000 grape vines from California, and wrote specific directions for root and top pruning as well as packing, and offered to pay for the extra pruning, the box to be sent by express. The nurseryman setting me down for a crank or fool packed the vines—top, roots and all—in three immense bales weighing 1,300 lb., for which he got a special rate, and yet they cost me £14 charges. I pruned and packed them in a single bale weighing 127 lb., and shipped them 250 miles, after which they were set by being simply stuck down into well pulverised ground and tramped, the whole operation taking but two days. Every vine grew, and next summer—the third year—I expect to ship grapes by the car load. It would be hard to estimate how many thousands of pounds are annually paid by planters to railroad companies in charges on worse than useless tops, roots and packing.

"HUNDREDS OF POUNDS WILL BE SAVED IN THE PLANTING.

Instead of large holes and spreading out of roots, and working in the soil by hand, as now practiced, the planter will prepare his ground, stretch a strong line with tags tied at the right intervals, make a small hole with a dibble a couple of inches in diameter, stick the trees down the proper distance and when the row is done, turn back and tramp thoroughly. The tramping is very important, I will now repeat.

"DIRECTIONS FOR ROOT PRUNING.

Hold the tree top down, and cut all roots back to about an inch, more or less, sloping the cuts so that when the tree is set the cut surface is downwards. Experience has shown that these roots are generally emitted perpendicularly to the plane or surface of the cut. This final pruning should be done shortly before planting, so as to present a fresh surface for the callous to form. If trees are to be kept some time, or shipped by a nurseryman, about two inches of root should be left the planter to cut back as directed when the tree is set. About a foot of top should be left. More or less makes no difference. If the tree is well staked, three feet may be left without diminishing the growth much. I have had six foot trees, well staked, to grow finely, but to avoid staking and to secure a new straight body it is best to cut back short.

"Let all shoots grow until a foot or so long, when the straightest and best should be left and all others rubbed off.

"I could give the experience and endorsement of quite a number of orchardists who have practiced this method with uniform success, but space will not allow me to mention but one. He stands on the topmost round of the horticultural ladder, and as far as I know is the only man whose mind is so unbiassed by the prejudice of preconceived opinions, and his perceptions so intuitively correct, that as soon as the method and reasons for it were presented, he saw its truth. Without waiting for the slow

demonstration of experience, he at once put it in practice on his great 900-acre peach orchard of 100,000 trees, which he was about to plant in Georgia. I wrote him recently as to how it turned out. Here is the reply:—"Dear Sir, I am glad to state that the close root pruning, which was practiced when planting our entire orchard of one hundred thousand trees at Fort Valley, Georgia, proved to be the most successful operation we ever practiced, less than one-half of one per cent. of the trees failing to grow and all making the most vigorous and even growth I have ever seen in any orchard in America. The orchard is now three years old, and gave us an enormous crop of fruit this past season. I am thoroughly in favour of this system of root pruning.—Yours very truly, J. H. Hale."

"And now in conclusion, in view of the fact that my individual effort of eight years have amounted to practically nothing, the question is how to bring about in the general handling of trees this radical but needed reform. I see but two ways. The first through the medium of the nurseryman and his catalogue, and the second through the bulletins of the experimental stations. Quite a number of nurserymen are now practicing my method exclusively, and with perfect success, in all their nursery transplanting operations, but they dare not advise the people to adopt it for fear of being accused of trying to induce them to kill their trees, so as to sell them more next season. Mr. Hale is the only exception I know in the whole country who comes out boldly for close root pruning. Now let all the rest make mention of the subject in their future catalogues; next let the State experimental stations make exhaustive experiments on all kinds of trees, vine- and small fruits, planting some with mere stubs of roots—a half-inch—and others with five, ten, fifteen and twenty inch lengths, setting enough of each to allow of taking up some every year to demonstrate at once that beyond a length of two or three inches the quantity and size of the new roots is invariably in an inverse ratio to the amount of old roots left on. The more and longer the old, the less, more lateral and weaker the new ones.

"Let them subject trees of different ages and length of tops to four or five years of the same treatment, and the result will be the same. The older close root pruned, even with four-foot tops will, if staked, quickly re-establish themselves on strong, deep, new roots and make fine trees, while the same age long root ones will become permanently surface rooted and dwarfed for ever. No amount of fertilizing or cultivation will ever make them catch up."

"REMOTENESS OF THE RUBBER SUPPLY"—is the heading of an interesting paragraph in the *India Rubber World* of June 10. It runs as follows:—"An illustration of the remoteness of the forest end of the crude-rubber trade came to light through the death in London, recently, of Francisco Saurez, an India-rubber merchant in that city, and consul-general for Bolivia, of which country he was a citizen. The estates on the river Beni from which he received rubber are 3,000 miles from the seaboard, with such slight means of communication that months are required for a letter from London to reach Mr. Saurez's relatives remaining there. The course of business was for rubber to be shipped to England against bills accepted by Mr. Saurez. After his death bills continued to mature until there was a large sum which could not be honored without the appointment of an administrator. Besides, a large quantity of rubber lay at Liverpool waiting to be cleared, and many persons were anxious to have arrangements made for carrying on the business. Application having been made in proper form, Mr. Justice Barnes named a chartered accountant as administrator to superintend the business until the next-of-kin can be communicated with."

JAVA AND CHINA VERSUS INDIA AND CEYLON TEAS.

In the *Indische Mercur* of 22nd May is the following letter which is worthy the attention of Ceylon tea proprietors:—

The Soekaboemi Agricultural Association, Soekaboemi, Java.

Gentlemen,—We are much obliged by your sending us the report of the general meeting of your Association, held on 14th Feb. last.

With regard to the article *tea* we noted with great interest your interesting communications, and we share your optimistic opinion regarding the vitality of the product of Java and the bright prospect that it has in the consuming countries, through further improvement of the intrinsic value. The consideration given to the improvements which are constantly taking place in tea machines, the attention paid to the soils, and what manner yields the best results, convince us that they must have great influence upon the quality of this product.

Although we do not wish to arrogate to ourselves the competence to pose as critics, we cannot refrain from giving you our opinion regarding some passages in your annual report.

You write:—"But care must be taken in time to give to the Java tea cultivation, the extension of which at the moment it is so susceptible, in order that we may supply with our expected increasing reports of Java teas a portion of the 40 millions of half-kilos of tea per annum from China, which will gradually disappear from the World's markets."

We ask ourselves: Is the tea cultivation in China then really doomed to a universal decline, simply and solely because Great Britain by its notorious "puffing" system partly damaged it to supply consumption through other channels? According to the enclosed statistics, covering the first four months of 1897, it seems that the deliveries of China tea in England amounted to 12,444,900 lb., against 12,979,550 lb. in the same period in 1896, from which we may assume that the very great falling-off, visible in former years, has at least for the moment stopped. We have the honour to send you, in further elucidation of this point, some graphic statistics, appearing in the *Beiblatt zur Kolonialwaaren Zeitung*, from which it appears that the consumption of China tea in England during the last few years shows more stability.

We notice an undesirable factor, according to a statistical statement also given therein the steady—and noteworthy—*increase* of the consumption of China tea in Germany, which we allege in the sentence occurring in our French market report for 1896 sent to you: "La consommation de thé de Chine fait encore tousjours beaucoup de progrès sur le continent de l'Europe et a gagné depuis l'année passée surtout en Allemagne, en Autriche, en Suisse et dans plusieurs autres pays."

According to our opinion the consumption of Java tea is closely united with that of China tea, and the former class is better suited than any other kind for mixing with the latter, which if drunk by itself is far too thin in liquor. It is just in this that in our opinion lies the strength and future of Java tea, as being a characteristic by which the latter enjoys the advantage over its keenest competitors (Ceylon and Assam tea) with the tea blenders of the continent.

Java tea cannot hope for salvation from Great Britain in a fraternal reception by the side of Assam and Ceylon tea. Such a thing might be possible did no "puffing" system exist; and this characterizes the whole English community, from Mincing Lane even to Johannesburg. They are very willing in London to take notice of Java tea as a surrogate (with or without reason; since Java is not a British colony), but especially if the chest is marked "Assam"! The great indifference on the part of the British towards Java tea we could demonstrate to you and confirm by many proofs.

Much rather do we regard Java tea as "concurrentfähiger"—competitor—of the British colonial product, were it solely from a dietetic point of view on account of the smaller amount of tannin. We have in view on Amsterdam or Rotterdam as emporium and universal market for Java tea in competition with a London as Assam and Ceylon tea market. It will not want for interest and active measures in this country, and the Dutch tea market will undoubtedly, with an energetic and united advance, be able in the future to reckon on a good reception from the continent, where the consumption of tea is each year spreading so much. We quote *inter alia* from the report of the Dresden firm of R. Seelig and Hille: "Java-thés finden nur in unteren Preislagen bei uns Verwendung, Konkurrenzen aber schon in besseren Qualitäten mit den besten Indischen Garten-Marken!" [Java teas with us are employed only in low priced grades, but in better qualities compete with the best Indian garden marks.]

Whilst we ask you kindly to accept these opinions for what they are worth, we also presume to draw your attention to what may possibly be in the future a dangerous competitor of Java tea in the form of the "New Process, machine made, China Tea," imported to London. An article in the *Indische Mercur* of 19 December last regarding this new product led us to place in the hands of the Editor the samples sent to us by our London broker for report, and these in the view of those interested, were a small contribution to a large supply. We observe that these teas were shipped from Foochow, whilst in the preceding week a parcel of the same merchandise was sold, which come from Hankow. We have pleasure in sending you herewith the samples of these parcels as also the sale catalogue, being the first machine-made Hankow teas. Meanwhile we remain, gentlemen, with much respect,

WED. J. VAN DER CHILJS & ZOOU'S
TEA DEPARTMENT,
J. VAN DER CHILJS.

12 May 1897.

PLANTING NOTES.

SHIKARIS who suffer from mosquitos will be glad to hear of a protection which is warranted on Consular authority to be efficacious. It is the essence of "Mentha Pulegium." On going to bed apply this sparingly to the face and hands and the mosquitos will not trouble you. So the British Consul at Naples declares. The remedy has not a pleasant odour, he admits, but it produces no evil effects and affords relief unspeakable.—*The Asian*, June 22.

A COMPETENT BRAZILIAN AUTHORITY on coffee, states that although the drop in prices, as compared with normal quotations is about 40 per cent, the prices in export markets afford the planters a profit of 80 per cent. on the cost of Production, and if this return is not adequate to the requirements of the planters, the cause must be found in the maladministration of the estates, few of which are personally superintended by their owners.—K. J. K. in *P. World*.—[Who is the competent authority? We doubt his reliability.—ED. T. A.]

THE FUTURE OF RUBBER.—The following is rather an important announcement for rubber cultivators, because the prospectus received by us by a previous mail was quite formidable as to what the proposed Company was likely to do in collecting rubber in West Africa with its £200,000 of capital. Now the proposal has collapsed:—

The British Indiarubber and Exploration Company, Limited.—The directors having deemed it inexpedient to proceed to an allotment of shares in the above Company, the moneys subscribed by applicants for shares and debentures will be returned in full to the applicants.—*Daily Chronicle*, June 5.

THE COFFEE SITUATION.—Thirty years ago, writes the *American Grocer*, the total consumption in Europe and the United States was 375,000 tons; today it reaches 650,000 tons, a gain of over 73 per cent. But while this gain covers thirty years, we have to recognize that during the past three years the annual deliveries in Europe and the United States do not average any larger than for the nine years 1880-1888, when they were 658,066 tons annually. The previous era of low prices during which consumption steadily increased ended in 1886, followed by a rise in 1887 to 18-11 cents as the yearly average cost of fair to prime Rio, against 10-76 cents in 1886 and 8-96 cents in 1885. Since then high prices have ruled, stimulating production in Mexico, Central America and South America, the effect of which was not felt until last year and still more this season. The total deliveries for ten months are reported by the Coffee Exchange at 10,095,554 bags. It is probable that the year's deliveries will be close to 12,000,000 bags, making the heaviest on record. The visible supply of the world, May 1, 1897, was 4,348,799 bags, an increase from July 1, 1896, of 1,760,606 bags. Increased consumption, with increased stocks and declining prices, are proof of overburdening supplies. If the 1897-98 crops are as heavy as those of 1896-97, we may see lower figures than any ever made, in spite of improved business. Which ever way the trend is, it is certain that coffee is low enough to warrant liberal buying and generous stocks.

"COFFEE NO LONGER KING IN THE EAST."—So we ventured to state some time ago in contrasting the position of our old staple in the East with what we see of it in Brazil, Mexico and Central America; and our position is strictly accurate in every respect. Even in Java, coffee is far below its old status, while tea, cacao and cinchona divide attention. Any planting in the Straits or Southern India has as yet done nothing in crops and exports to retrieve the position. But a young and rather rash planting contemporary in India challenges our statement after a fashion peculiar to inexperienced youngsters:—

"Extremely elementary notions must our contemporary have of the conditions that obtain in South India, where there are about 15 acres of coffee to every one acre of tea. It would probably surprise it to learn that the last six years or so have witnessed an unprecedented rush for coffee land and so-called coffee land (thought formerly only fit for grazing) in every district—barring Travancore—in Madras."

The "chaff" follows. A "six years' rush;" and yet three years or at most four bring coffee into bearing. How then do the export figures for India bear out the above statement:—

TOTAL COFFEE EXPORT FROM INDIA:—

1871-2	..	507,000 cwt.
1881-2	..	351,981 "
1891-2	..	311,864 "
1895-6	..	290,902 "
1896-7	..	210,707 "

No sign of "a six years' rush" in these figures, but rather of a steady decline.—Here again is the figured picture which justifies our statement that "coffee is no longer king in the East:—

	cwt.	now	cwt.
Ceylon (max. annual export)	1,000,000	now	40,000
India	510,000	"	220,000
Java, Straits and E. Archipelago	2,000,000	"	1,200,000

3,500,000 1,460,000

While the "West" which 20 years ago produced not much more than the "East," now produces over 12 million cwt. or eight times as much as the "East."

CACAO CULTIVATION IN CEYLON.

At the time when the fear of overproduction is the strongest sentiment prevailing among tropical planters, it is refreshing to find one exception, at least, and that is in respect of the cultivation of Cacao in Ceylon. On the principle of the survival of the fittest, we would fancy that proprietors not afflicted with disease in their shrubs or trees,—or only with such passing attacks as Cacao is subject to, above all products up to a certain age,—should feel increased confidence in the value of their properties as they saw the discouragement given to further cultivation around them. But the cry has been not to say too much of prevalent troubles lest the value of property should be depreciated. There is no fear of that, after the letter Mr. J. R. Martin sends us (see page 125). Profits ranging from 12½ to 18 per cent on the capital invested ought to be good enough even for the exigent tropical planter. And when such are got from crops ranging from 2 to 3 cwt. per acre, it is evident that there is really much encouragement to turn Cacao planter; for such crops—returning all the husks to the soil—cannot be called an exhaustive one. Now as regards the pests to which Cacao is liable, we should like to know if Ceylon planters have really any different experience from their brethren in the Far West. The testimony coming from the Guianas—British, Dutch, and French—from Trinidad and Mexico, goes to show that no more troublesome product to the planter, in reference to the number and variety of its enemies, exists than Cacao, up to the time the trees are ten years old or so; but after that, few if any give less trouble. The enemies disappear or the trees are strong enough to resist them. Now, we know that there have been individual experiences in Ceylon which contradict this Western deliverance and we know also that “poochies” even now in some parts are injuring not only 10 but 15 and up to 20 years’ old trees. It is clear, therefore, that the sooner Mr. Green is put to work as Entomologist, the better; and we should say he ought to begin by visiting and conferring with the planter of longest experience in each district:—with Mr. Martin in Matale North visiting the adjacent estates; with Mr. Van Der Poorten in the Kurunegala side visiting the Polgahawela division; and with one or other in Dumbara and Wattagama districts. In this way, the Entomologist could not fail to see and learn a good deal that should help in deciding as to the wisest course to pursue in reference to a systematic examination and report on local cacao enemies, their operations and the way to check or get rid of them. The subject of cacao cultivation is of so much interest at present that we shall treat it further later on.

INDIAN AND CEYLON TEA.

ANNUAL REVIEW.

38, Mincing Lane, 9th June, 1897.

In accordance with custom we take the opportunity of the completion of another period of twelve months, dating from June 1st, 1896, to publish in detail the figures relating to Production and Consumption, and the development of Home and Foreign trade;—together with such information respecting the results of the Indian crops sold in London as by the courtesy of our friends we are enabled to print.

There is much in these figures encouraging to all who are interested as Producers in the growth of the trade in Indian and Ceylon Tea. The continuous increase

in Production has been accompanied by a steady growth of Consumption; not, indeed, at home, sufficient to absorb the increase in supply, but still, such as to maintain prices, speaking generally, at a fairly remunerative level; while abroad, sufficient progress has been made to exercise an influence upon value, and to justify confidence in a wider development in the future.

It is obvious that so great a decrease in the use of China Tea at home having *already occurred*, and its place having been *filled* by British-grown tea, the rate at which consumption of the latter grows will not be rapid in the future, unless something exceptional should happen to stimulate it. The following figures illustrate this:—

Proportions in which the different growths were used in the United Kingdom.

	1891-2	1893-4	1895-6	1896-7
Of China, &c.	.. 21%	13½%	11½%	10%
.. British-grown tea	79	86½	88½	90

The ability of the home market to take larger quantities is, therefore, becoming mainly dependent upon the greater consuming power of the country in the aggregate. So far, this has shown continuous and steady growth; and, we think, apart from the increase in population (1) to the facilities given to the public, by purveyors, for obtaining a cup of tea of good quality is now obtainable from all the principal vendors. It is not an exaggeration to say that to a large part of the population the good tea of India and Ceylon has become an almost necessary article of diet, cheaper and more exhilarating than any of its rivals.

But these causes have now been for some time in operation in London and other great centres, if not in the country; and it would, therefore, be unsafe to reckon upon home consumption expanding in the future as *substantially* as it has for the last two years. In view, therefore, of the increased supplies expected in future years, the need of turning to the large and, as yet, almost unopened outlets for our teas abroad becomes more imperative than ever;—and whichever means of finding the way into new markets may prove most effectual, there is scope for operations varied in method and wide in application. As pioneers in this work, those representing the Planters’ Associations have done good service; for their distribution of information respecting the production and preparation of our tea is in itself of the highest value—bnt in the long run, and for large results, reliance must be placed upon the ordinary channels through which trade flows. It is, therefore, opportune that the system of sending out tea as a proprietary article, under a registered title, has been so widely adopted, as it is perhaps more conducive than any other to place our teas where they were unknown before and enable consumers to obtain a regular supply.

The progress made in trade abroad, through the medium of London, is shown by the following figures relating to Exports from the United Kingdom:

Out of the total	1891-2-3.	1893-4.	1895-6.	1896-7.
China, &c.	.. 80 %	76½ %	62½ %	59 %
British-grown tea	.. 20	23½	37½	41

In conjunction with the increasing shipments to Asia, Australasia and America direct from Calcutta and Colombo, these statistics prove that progress is constant, if a little slow.

Wide fields lie open before us—and the possibilities of the future, if our taste for tea were to extend to those whom we influence, find a vivid illustration in the following figures:

The British Race in the United Kingdom takes annually	228	} equal to 5 ¾ lb. per head per annum.
“ “ “ in the Australasian Colonies annually	23	
“ “ “ in the Dominion of Canada annually	22	
That is to say, about 49 millions of people take 278		

Whereas, in the United States of America, 65 millions of people use annually less than 1½ lb. per head.

In Russia 100 millions of people use annually less than 1 lb. per head.

In Germany 53 millions of people use annually less than $\frac{1}{2}$ lb. per head.

In France 38 millions of people use annually less than 1-32 lb. per head.

Moreover,—is there any reason why a sustained attempt to popularize their native product among the countless millions of *India itself* should fail? Can no methods be devised for putting tea within their reach at a price and in a form which might eventually lead them to use it as a beverage as freely as the Chinese and the Japanese use the produce of their soil?

The successful development of the system of selling tea under a registered name is, in conjunction with the Blender's business, transforming the methods by which the Tea Trade is carried on—and is attended by a material effect upon the London market. It has brought in a large amount of fresh capital seeking remunerative employment, and has placed ample means at the disposal of traders with progressive ideas who realize that in order to make and keep their business they must supply the public with good tea at moderate prices, and outdistance their rivals—if they can—by the merit of the article sold.

In this we find the explanation of the fact whereas most retailers say they sell less high-priced tea than formerly, they nevertheless compete keenly all through the season for the choicest growths that come to market, and pay more attention to fineness of quality, and especially to "*flavour*," than ever before.

Evidence of some movement in the *relative values* of produce correspondent to this tendency will naturally be sought for: and it will be found in the gradually widening margin between the value of the best teas and those of ordinary or inferior class, which has characterized the market during the last year or two, and is illustrated by the records of crop results printed herewith. There may possibly be another cause of the appreciation of the value of the finest growths of India and Ceylon, in the fact that their production does not, and indeed cannot, increase so rapidly as that of inferior qualities, owing to the limited area in which choice teas are produced. But there has been *no lack* of fine tea this season—the Assam and Darjeeling crops having contained a fair supply, while in Ceylon the best districts have on the whole maintained their reputation.

As regards Darjeeling, allowing for irregular results due to climatic influences, it is becoming evident that its produce tends to become intrinsically more valuable as a whole:—while with regard to Assam the high standard of quality reached and uniformly maintained in certain parts has been so noticeable as to warrant the conclusion that methods superior to those formerly followed, by slow degrees brought to perfection by skillful managers, have been adopted by others in the locality, to the general benefit of its produce.

Whether the tendency of prices to widen in their range will continue; and whether it will find expression in higher rates for "fine" or in lower quotations for "common," are questions which time alone can decide:—but inasmuch as the contributory causes, to which we have alluded, are likely to be permanent, it is not unreasonable to look for some movement in each direction. An influence not to be overlooked is the gradually growing enquiry for *fine-flavoured* tea from abroad, not yet sufficient to affect the value of the larger supply from India, but already so constant as to raise the level of rates for the smaller quantity produced in Ceylon.

This is a matter of deep concern to those engaged in extending the area under plant, as it has a direct bearing upon the two alternative policies, viz.; whether to open up new districts whose ability to give good tea is doubtful, or to concentrate energy and capital upon more favoured localities. As regards districts where large crops can be produced at a low cost, it is obvious that if the value of such tea as they yield should decline much more, and cost be enhanced by higher exchange or difficulty in getting labour, the present margin of profit would disappear. It would be unwise to disregard the contingency of a further fall in the value of common

tea, in view of the extensions made in recent years in districts which yield it, and of the possibility that however steadily the world's demand may grow, it may not expand *fast enough* to keep pace with the output.

This is an eventuality suggesting discriminating caution in breaking new ground, and the devotion of far more attention to the quality of produce than to the output of a heavy crop.

There are processes involving expenditure of time and labour—*e.g.*, excessive manipulation of leaf for purposes of classification, and factory-bulking (save in exceptional cases), which are of secondary importance compared with attention paid to work in the *field* and in the *tea-house*:—sometimes, indeed, they impair values, and they seldom raise it.

The needs of the day are to bring tea rapidly to market; at regular intervals; in as large breaks as can be made; sub-divided into the four or five recognized grades; to break the leaf as little as possible by mechanical process; and to maintain the distinctive character of the garden's produce.

W. JAS. & HY. THOMPSON, Brokers.

THE CEYLON AND INDIAN PLANTERS' ASSOCIATION, LIMITED.

(Incorporated under the Companies Acts 1862 to 1893.) Share Capital £120,000, Divided into 4,000 Cumulative Six per Cent. Preference Shares of £10 each, and 8,000 Ordinary Shares of £10 each. Directors.—Charles Arthur Reiss (L. Reiss Brothers & Co.), 51, Lime Street, E.C., Chairman; Keith Fraser Arbuthnot (Sanderson & Co.), 37, Mincing Lane, E.C.; Charles Frederick Dickinson, 41, Eastcheap, E.C.; John Humphery (Hay's Wharf), Southwark, S.E. Prospectus.—This Company was formed to carry out a Contract for the purchase, as going concerns, of the three well-known Ceylon Tea Estates, called Maha Eliya, Laxapana and Kandal

Oya, and to acquire other estates in Ceylon, India, and elsewhere, from time to time, as and when favourable opportunities occur. The particulars and acreage of the Estates now acquired are as follows:—

Name of Estate	ACREAGE						Total Acreage
	Tea in Full Bearing	Tea in Partial "	Young Tea & NURS.	Cardamoms	Forest	Grass	
Maha Eliya, Dimbula Dt.	248	15	2	..	40	..	365
Laxapana, Maskeliya Dt.	640	48	128	..	89	20	1021
Kandal Oya, Yakdessa Dt.	468	26	136	4	345	3	1006
Acres.	1356	89	266	4	474	23	2332

The Estates will be taken over as from 1st July next the Company receiving the crops and paying expenditure from that date.

For the Season ending 30th June 1896 the crops were as stated below, and the average selling prices for the year 1896 are set against them. The returns for the current season are not yet complete, but an increase upon the previous year's crop is anticipated.

Crop.	1st July '95 to	Average
	30th June '96.	Selling Price '96
Maha Eliya	.. 119,003 lb.	9d
Laxapana	.. 260,081 lb.	8½d
Kandal Oya	.. 176,030 lb.	6½d

555,174 lb.

The price to be paid for the properties is £81,000, payable as to £76,000 in cash and as to £5,000 in fully paid Ordinary Shares of the Company.

Under the Contract for purchase the Company have the right to require any part of the purchase-money, not exceeding £56,000, to remain on Mortgage of the estates for three years at 25 per cent. interest, with the option of paying same off at any time. The Directors propose to exercise that right now to the extent of £40,000, and, later on, to pay off that mortgage out of the proceeds of an issue of debentures to be created and secured by a first charge on the Company's estates. The estates are well equipped with factories, machinery, bungalows, buildings and coolie lines, sufficient for all their present requirements. Mr. George Greig (who has for a number of years had charge of the estates) has expressed his readiness to accept the post of Resident Manager in Ceylon, for a period of five years, and has shown his confidence in the future of the Company by applying for £5,000 in Ordinary Shares.

The tea crops for the coming season are estimated by Mr. Greig at 570,000 lb., and he puts the up-keep expenditure for the same period at R154,000.

Taking the net value of the Crop in London, after payment of freight and all charges, at 6½d. per lb., the proceeds would be	£16,030
and deducting Ceylon expenditure, R154,000 at Ex. 1s 2½d.	9,504
there should be a profit of	£ 6,726

This would suffice to pay on the present issue,		
Interest at 5 per cent. on Mortgage, or on Debentures issued	£2,000 0 0
Preference Share Dividend at 6 per cent.	900 0 0
Ordinary Share Dividend at 10 per cent.	3,000 0 0

It is confidently expected that the returns from these Estates will go on increasing, as at present there are 89 acres of Tea in partial bearing, and 245 acres planted and yet to give crop; moreover, the Directors propose to plant up further land with Tea from time to time as occasion offers.

PLANTING AND AGRICULTURE IN KINTA, STRAITS.

(From Mr. Wray's Report for 1896.)

A large area of land has been taken up for coffee and other permanent crops, and a considerable proportion of this has been already cleared and planted. Mr. F. D. Osborne has a large acreage in Liberian coffee, some of which is bearing, and he has also a fruit plantation on the Tamban Road, which promises well. Messrs. Osborne, Leech and Pike—Mr. Foo Chu Chun—Messrs. C. Epiracums and Crawford—Messrs. Dykes and Leong Fii, and Mr. W. Smith, have also promising coffee estates. Mr. C. G. Ogilvie has about 360 acres in coconuts and coffee, and Messrs. J. Paton Ker, Lutyens, and others, have grants of land on which work has not yet been commenced. Besides these large estates there are many smaller holdings belonging to Malays and other Asiatics, notably a very prettily situated estate of about 100 acres belonging to Dutch Pandak, Ahkat, Penghulu of Sungai Trap.

Very little has been done so far for padi planting, but a great deal of land has been taken up, and there is every reason to hope that a large quantity of rice will be grown here in the near future. The prolonged drought this year shewed how necessary irrigation is for most of the padi land in this district, if rice-growing is to become an important industry. Some years ago Toh Muda Wahab commenced a very large scheme for the irrigation of the large area of land lying between the Pinji and Kinta rivers, and he has spent in all a sum not far short of \$30,000 with, however, but partial success. He has dammed up about 650 acres of water but, owing to the work having been undertaken without professional advice, the dam is continually giving way. He petitioned the Government for assistance, and at the latter part of the year Mr. P. B. McGlashan was told off to inspect the dam and advise him as to the completion of the work, and there is now every hope that the several thousand acres of land below the dam may prove profitable. The Dutch Panglima contemplates undertaking an important irrigation scheme from the Ulu Pari, which will water a large extent of *bandang* near Ipoh. There are other places in which, by a moderate outlay, considerable tracts of fertile land can be brought under cultivation, notably in the Kamper valley.

In view of the fact that buffaloes appear to be rapidly becoming extinct in this district, it is most important that the Malays should be taught to use ploughs, and so become independent of these animals. When asked why certain land is lying idle the answer is almost always the same, "We have no buffaloes."

PLANTING IN BRITISH CENTRAL AFRICA.

Mr. Israel's place at Chipende, we hear, is looking bright and healthy as usual, and a considerable area of new land is being opened up. Altogether Mr. Israel's place is a conspicuous landmark in the distance.

The Lunze and Chiračulo estates of Messrs. Buchanan Bros. are also looking in fine condition, and a very fair return is expected from these plantations this season.

Mr. R. H. Balfour Blair—who recently bought from Messrs. Pettitt Bros., several hundred acres of land down Nalomwa way—Eastern part of Cholo—is at present busy clearing and pitting.

Messrs. Cox Brothers have succeeded to the superintendence of Messrs. Buchanan's plantations in the Cholo district. The place, we hear is looking exceedingly well, and showing up for a handsome crop this year.—*Central African Planter*, May 12.

CINNAMON SALES IN LONDON, AND THE CULTIVATION IN CEYLON.

The particulars which have come to hand of the last quarterly Cinnamon Sales held in London on the 31st May, are not quite so satisfactory as were many of the preceding reports in regular succession. All the offerings were not sold—only about one-half, or 880 bales out of 1676 having been disposed of by auction; and the prices for ordinary bark fell from ½d. to 1d. per lb. We cannot say we are surprised at this result. Although, undoubtedly there has sprung up a better demand for cinnamon, and the advance in prices which we have recorded for the last two years is obviously due to this improved demand which, there is every reason to believe, is not merely temporary, the quantities sent forward lately were such as to cause some anxiety. Thus, the total exports for last year amounted to 2,223,865 lb. quilled bark against 2,169,527 lb. in 1895, and less than 2 million lb. during the three previous years. In chips there was some falling-off—808,502 lb. against 920,136 in 1895; but in no previous year had even 700,000 been touched! The advance must, therefore, be taken as very considerable last year as compared with previous exports; but it is when we come to this year that we find a yet greater growth in exports. Thus, up to the end of last month, practically, we sent away no less than 995,649 lb. of quilled cinnamon and 630,852 lb chips, as against the following quantities for the corresponding period of the three previous years:—

	Quills.	Chips.
1896 ...	859,999	425,444
1895 ...	693,891	413,292
1894 ...	616,000	276,493

The progressive increase, it will be seen, is very considerable under both heads; and it is not surprising that prices have receded somewhat in the face of such heavy landings. The gradual development of a demand is one thing, and the ability to take up immense quantities thrown into the market on short notice is quite another thing. Still, there is no cause for anxiety or despondency. The falling-off in price was far from serious, considering recent successive rises; the finer qualities maintained the high prices which they had commanded at the previous sales; and all the "worked" cinnamon sold, while the prices realized for "unworked" did not compare unfavourably with those which "worked" parcels fetched.

Where there is cause for apprehension is in connection with the extension of cultivation. Past experience seldom counts when a product realizes high prices. As in gold mines, so with agricultural products—Tea, Coffee, Cinnamon—a rush follows remunerative prices; and we already hear of large quantities of cinnamon seed being sold for nurseries—especially in the Southern Province. Last year the demand for seed was strong. This year it is stronger. We do not believe that Europeans or the better educated Ceylonese are likely to rush into so

sensitive a product, and one so difficult to harvest, as cinnamon; but native gardens will extend and multiply, to be followed by over-production and a drop!

A Colombo merchant sends us the report of the "London Commercial Record," 4th June, from which we take some pointed remarks with reference to the fall in prices at last sale:—

Whether the result would have been a different one had the contingent of buyers been a representative one, is a difficult question to answer, the absence of two of the principal buyers may have had some weakening effect on prices, yet we are inclined to believe that their presence would have made little difference, for the dulness just prior to the sales may be accepted as a fair criterion of the feeling of the entire trade. Holders here were greatly upset by the arrival of numerous consignments, and seemed to have been determined from the very first not to support the market, in order to nip in the bud a trade which, if at all encouraged, would quickly develop into a dangerous opposition to the existing manner and custom of dealing in Cinnamon. In this respect holders here have acted quite correctly, for there is not a more dangerous enemy to the steady, legitimate business than the swamping of our market with cheap and low native consignments. We have had occasion to witness their nefarious results on several markets, and we are glad to see that at least in the present instance the prices relised are not exactly encouraging to the consignors. Cinnamon, after all, comprises but few supporters, and it should therefore not be a difficult matter to effectually oppose the introduction of the consignment system on a large scale. The first step has been one in the right direction, and we are satisfied in our own mind that the account sales forwarded to Ceylon showing short proceeds will have a most cooling effect on native shippers. Some efforts has been made in certain quarters to stem the tide of delinving values by spreading the rumour that an important house of shippers was anxious to depress the market in order to facilitate the coverture of their blank engagements, but as this rumour did not receive any support or even confirmation, its effect upon the minds of the trade was nil. In fact, in some instances this ill-found rumour resulted in an almost contrary effect than anticipated by its originator—it helped to depress prices. Colombo in the meantime appears to have been little affected by the drop in our market, which, however, is not surprising, considering that the old season is at an end and the new not yet begun; but there can be little doubt that as soon as supplies begin to arrive over there on a large scale, prices, not being supported by a European demand, will steadily come down, and will adapt themselves to the level of our range of values. On the 1st of this month the new standards of usual assortment came into force, and their working will be interesting to watch, for the opinion on the advisability of their adoption still differs considerably. So far shippers have asked ¼d per lb. more for the guarantee of "equal to standard" over the usual fair merchantable, but this difference we feel sure is only attributable to the uncertainty which prevails as regards the working of the standards, and not to an appreciable difference between the old and new guarantee of quality. Practical experiments alone will show whether the adoption of standards was a wise step to take or not.

DEAFNESS. An essay describing a really genuine Cure for Deafness. Ringing in Ears, &c., no matter how severe or long-standing, will be sent post free.—Artificial Ear-drums and similar appliances entirely superseded. Address THOMAS KEMPE, VICTORIA CHAMBERS, 19, SOUTHAMPTON BUILDINGS, HOLBORN, LONDON.

COFFEE IN SERDANG, SUMATRA.

An old planting friend writes:—

Serdang, Sumatra, 15th June:—Unprecedented rain these last days. Roads are terrible. Health good and labour plentiful. Coffee planting is making rapid progress, and weeds are also taking advantage of the fine growing weather. The rinderpest has at last abated, and our roads are once more opened for bullock traffic, having been closed for over two months. Difficulties of transport during this period have been beyond a joke. Crop is ripening up rapidly and coming in hand-over fist. One estate is said to be picking 17½ pikuls per acre from its four years old coffee, *i. e.* over a ton an acre. This makes one's mouth water. I doubt if British India, Ceylon or Java has ever equalled it. It seems that Serdang is not to be the only coffee growing district of the East Coast. It is being planted in parts of Deli and Langkat, and I hear that some who have come too late for land in Serdang are opening in Assahan.—*Singapore Free Press*, June 22.

COCONUTS AND RICE IN THE EASTERN PROVINCE OF CEYLON.

The highly satisfactory results which are seen on all sides of a vigorous irrigation policy which has been steadily carried on for the last thirty years, and the large area under coconut cultivation, call for early action on the part of Government to improve internal communication and facilitate transport of produce. Every encouragement should be given towards the improvement of the steam service on the lake. Among the schemes mooted for the development of the resources of the Province, and one which deserves favourable consideration, is the construction of a light railway from Batticaloa to the foot of the Madulsema hills. The country which it would traverse presents no physical difficulties, for the first 30 miles is almost a dead level and the remaining 25 miles slightly undulating land. A railway like this would enable the ricegrower to transport his produce to the Uva estates and sell it there at a cheaper rate than the price paid for the imported rice.

The extent of land sold last year amounted to 3,886, the highest on record for the last ten years, as will be seen from the annexed statement:—(We quote three.)

Year.	Extent sold:		Amount sold for Rupees.	Average Price per Acre.
	A.	R. P.		
1894 ..	4,196	0 25 ..	80,146 ..	19 10
1895 ...	4,584	1 24 ..	77,797 ..	16 97
1896 ..	4,886	2 32 ..	72,871 ..	14 91

Also the following from Mr. Lushington:—The larger blocks were bought chiefly by Europeans for coconut planting, which appears to contribute so much towards the prosperity of the country. Very little new land has been opened for paddy, probably because the extent already brought under cultivation is so enormous as to leave little for further extension, unless new irrigation works are provided. In no part of Ceylon has irrigation produced such successful results as it has here.

Annexed is a statement of land under paddy and coconut cultivation:—

	Acres.
Paddy ..	67,377
Coconut ..	19,200

NEW AREAS OF CULTIVATION.

The first attempt to take up coconut cultivation on a large scale was made during the year past, when three blocks of land aggregating 504 acres were purchased for the purpose of growing coconuts. These lands are situated at Uppu-aru near the mouth of the Mahaweli-ganga, and seem to be well suited to coconut growing. Unfortunately, one of the purchasers, Lieut. Maloney, has left the Island. There is much land suitable for coconut cultivation in the district, and I hope to see a considerable extension of this produce within a few years. In addition to these

large blocks of land, 152 lots aggregating 551 acres were sold by the Crown, chiefly for paddy cultivation, much of the land sold being irrigated by Kantalai tank. Three acres were granted on payment of half improved value, and 55 acres were settled on certificates of quiet possession.

THE COST OF CITRIC ACID.—Messrs. Nascio, Aveline & Co., manufacturers of citric acid write from Massina that the present selling-price of citric acid is barely equal to the cost of producing the drug. They work it out this way:—The theoretical yield of one pipe of conc. lemon-juice (of 108 imperial gallons) at 64 oz. of acid per gallon is 432 lb. But in practice it is from 15 to 20 per cent less, according to the season and the expertness of the manufacturer. There is also a trade-discount given on citric acid, to meet which a further 5 per cent must be deducted from the yield—*i. e.*, in all 20 per cent, or 108 lb., leaving a net result of 324 lb. At £12 5s per pipe this makes the prime cost of crude citric acid 9d per lb. The cost of manufacturing, packing, &c., is close upon 4d per lb., making a total of 13d per lb., or, say, the same as the present selling-price.—*Chemist and Druggist*.

MANCHESTER GEOGRAPHICAL SOCIETY.—At a meeting of this Society Mr. A. T. Wardrop, Customs and harbour officer for the port of Sandakan, the chief seaport and capital of North Borneo, gave an address on "North Borneo, the new Ceylon." He described the country as wonderfully rich in natural products, and as likely soon to become an important centre for trade. Cotton, coffee, tobacco, and cocoa, he said, could be grown there easily; many plantations for the cultivation of tobacco and coffee were already established and doing very well. A railway stretching across the entire country would soon be completed; the telegraph and telephone wires were already laid, and great progress was noticeable in many other directions. Mr. Wardrop's story was confirmed by the Rev. Father Jackson, a Catholic missionary, who has spent several years in Borneo, and on a visit to Manchester attended the meeting in company with the Rev. Dr. Casartelli. The interest of the meeting was increased by the presence of two natives of Borneo, known as dyaks, or head hunters. They form part of the band which has been sent to England to take part in the Queen's Jubilee celebration, and are believed to be the first of the natives of Borneo to visit Europe.—*Manchester Guardian*.

HONDURAS AND ITS BANANA HISTORY is the subject of a consular report by Mr. J. Eugene Jernigan, the United States' representative at Utilla. He states that two islands in the bay of Honduras were the first to engage in banana culture for export, which is now the greatest of all the industries of Honduras. The Consul adds that there are no wharves, piers, or warehouses where vessels can take fruit in the Gulf of Honduras, and in most cases they are obliged by the treacherous coast to anchor a thousand yards or more off shore, and the plantation owner has to convey his fruit in small dories and skiffs through the surf to the vessel, where it is inspected and received or rejected. The Consul remarks, that the royal road to fortune through a banana plantation in Honduras is a myth. True, millions of the fruit are produced annually, but the price paid the producer in the great majority of instances is not greater than the cost of production and delivery alongside of ship. It would have been interesting if Mr. Jernigan had inquired into the causes of these low prices. Perhaps his district, like that of Belize, is a prey to the monopoly of a shipping company, to whom the merchant or the planter is bound to sell his fruit at whatever price the company likes to give.—*British Trade Journal*.

MARKET RATES FOR OLD AND NEW PRODUCTS.

THE AGRICULTURAL MAGAZINE, COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for August:—

Vol. IX.]

AUGUST, 1897.

[No. 2

SEASON REPORTS FOR JUNE.

ESTERN Province.—Yala crops

thriving generally; rainfall plentiful; supply of fruits and vegetables good and prices fair, except in parts of the Kalutara district; a good yala harvest is expected.

Central Province.—In Kandy district yala crop nearing maturity; in Matale (rainfall 12.36 in.) prospects of paddy good; in Nuwara Eliya maha cultivation in various stages from sowing to harvesting.

Northern Province.—Jaffna district: threshing of Kalapokam paddy in Karachchi division, in others fields being ploughed and manured. There were a few good showers of rain in Jaffna district but hardly any in Mannar.

Southern Province.—Yala paddy in ear and being harvested in some parts; a fair crop expected. Rainfall in Galle 6.98 in.

Eastern Province.—In Trincomalee the threshing of the early and late munmari over, yield low owing to damage by floods, the damaged crops are some 30,000 acres in extent; in Batticaloa pinmari being harvested in some parts, in blossom in others. Still some cattle murrain in Batticaloa district.

N.-W. Province.—Paddy in various stages, prospects good. The rainfall registered in Puttalam town was 3.17 in.

Uva Province.—Crop of malan fields harvested, yield good; in some places maha crop being harvested; vegetables plentiful and cheap.

Sabaragamuwa Province.—Paddy prospects favourable in Ratnapura and Kegalla districts, Rainfall at Ruanwella 13.22 in.

RAINFALL TAKEN AT THE SCHOOL OF AGRICULTURE DURING THE MONTH OF JULY, 1897.

Greatest amount of rainfall in any 24 hours on the 5th Monday inches .96

Recorded by A. R. JEREMIAH.

THE QUEEN AS AGRICULTURIST.

The Queen has during her long reign taken a keen and close interest in agriculture. Debarred by the laws of a limited monarchy from interfering in the internal affairs of Government, the lamented Consort of Her Majesty, the late Prince Albert, early turned his attention to the promotion of every scheme and cause calculated to ameliorate the condition of the citizens of his adopted land. The House of Hanover had always taken an interest in agriculture; the Queen's grandfather, King George III., was "Farmer George;" he loved the country and country pursuits, and was never better pleased than when, free from the cares of State, he could turn aside to examine his flocks and herds and converse with his stewards and bailiffs. But hereditary instinct alone would not have led to the close and

widespread connection of the reigning house with agriculture, had it not been for the advent of the Prince Consort and his enthusiasm for country pursuits. It was a striking tribute to his good sense, and an illustration of his ready adaptability to his surroundings, that, coming from the continent where the State did almost everything for agriculture, to Great Britain when it then did next to nothing, Prince Albert at once adopted English methods, and set about organising all kinds of self-help institutions, or strengthening those already in existence. For twenty-one years, it has been well said, he was in the forefront of every agricultural enterprise, and this period of wise activity was to have been fitly crowned with the presidency of the Royal Agricultural Society of England, in the year of its first great international show, when all the world was startled by the news of his sudden death on 14th December, 1861. It was part of the tribute which the widowed Queen paid to the memory of her Consort that she gave orders for the continuance of all his farming operations on the lines which he had laid down, and thus to understand Her Majesty's position in the agricultural world we must briefly sketch the agricultural enterprises of the Prince Consort.

The first property which H.R.H. set himself to improve was that of Osborne, in the Isle of Wight, which is now under the charge of Mr. Andrew Slater, formerly of Haystoun, Peebles. Incidentally, it may be remarked that Scotchmen have played an important part in the work of the Royal farms, the present as well as the past managers or factors on all of the estates being of Scottish parentage and born north of the Tweed. Mr. William Tait succeeded his father, the late Mr. Henry Tait, in 1882, at Windsor, and only recently Mr. James Forbes has succeeded the lamented Dr. Profeit at Balmoral and Abergeldie. The palace at Osborne was built from Prince Albert's own designs in 1845-46, and the surrounding estates, extending four miles in length and two miles in breadth, were laid out and vastly improved by Mr. Andrew Toward, under the supervision of His Royal Highness. He began experiments in sewage farming in 1851, and the expenditure on this estate during the forties was enormous. The horses used here from the beginning, and, indeed, still on all Her Majesty's estates, have always been Clydesdales. The stud at Osborne in the Prince Consort's time numbered from 24 to 30 head. A Clydesdale stallion was kept, and breeding systematically prosecuted. The other stock in the Isle of Wight are Jersey cattle for dairy purposes and Galloways for feeding. Dorset-horned and Southdown sheep have also been favoured in this department. The Prince was deeply interested in the improvement of the social condition of the labourers, and the cottages built by him were models. This trait has descended to his son, the Sandringham cottages in Norfolk being well known as desirable residences for a rural population.

The estate next purchased or leased was that now known as Balmoral, in Aberdeenshire. It lies near to the village of Crathie, about 52 miles W.S.W. from the Granite City. At first the property was leased from the Earl of Aberdeen, but in 1852 it was purchased. It contains 10,000 imperial acres, but the demesne was further extended by the purchase of Birkhall estate and the leasing of

Abergeldie Mains for forty years (1849-89), with final purchase since that date, so that the whole now extends to about 40,000 acres. It is on this estate that Her Majesty spends the greater portion of the year, and here in recent years has been founded a choice herd of Aberdeen-Angus cattle, as well as a small Hackney stud. The herd as made quite a name for itself already, and the fame of Eulenberg and Gentian is widespread. Every care is being taken to extend the usefulness of these cattle, and alike at the breeding and the fat stock shows the Royal blackskins have given a good account of themselves. Even more noteworthy than its agriculture is the forestry of the Queen's Highland property. Under the skillful management of Mr. John Michie a large additional area has been planted, so that on the estate there are now 5,700 acres of well-stocked woodland. This enterprise was commenced by Prince Albert, and probably on none of the Queen's estates did he leave the impress of his genius more clearly than on his Highland estate on Deeside. Doubtless to this is to be attributed Her Majesty's great love for her Aberdeenshire home—for she does nothing by halves. The roads, fences, and especially the cottages on the estate, are all so many monuments to Albert the Good; and it is impossible not to admire the many-sidedness of the German prince who could, and did, so readily adapt himself to the duties of a Highland laird. The traditions of the house have been thoroughly sustained by those entrusted with the control of affairs since the Prince Consort's death, and enthusiasm for the British Royal Family is at white heat in Deeside and Braemar.

Windsor is at once the most extensive and the most varied of the Royal residences and farms. At one time the Queen held five farms in the vicinity of Windsor Castle—the home or Dairy farm, the Prince Consort's Shaw farm, the Flemish farm, the Norfolk farm, and the Bagshot and Rapley farms. The last are now farmed by H.R.H. the Duke of Connaught, who entered on their occupancy in 1880, and all of Her Majesty's sons, it may be said in passing, while they resided in England, had farms of their own.

The dairy farm is that which first meets the eye of the visitor to the Windsor Great Park. It lies contiguous to the castle, and the dairy premises are well worth going a long way to see. They were built from designs by the Prince Consort, and finished in 1855. There is nothing at first sight startling about the appointments, but a leisurely examination reveals a wealth of detail in the construction of the premises which puts to shame anything we have ever seen in dairies, and well calculated to ensure the maximum of cleanliness with the minimum of labour. Space does not admit of a detailed description of these ideal premises here, but the curious will find an admirable account in Mr. Macdonald's article, entitled "Queen and Farmer," in the recent issue of the Transactions. Jerseys and Shorthorn crosses are the dairy cattle made use of at Windsor, but at Invergelder, in Aberdeenshire, the dairy herd is composed of Ayrshires, Her Majesty in this, as in everything else, acting with consummate tact, so that no portion of her subjects should have ground of complaint. Every breed is recognised in its own proper sphere, and, if all are not alike prosperous, the blame cannot be laid at the door of the Queen. The principal homestead

at Windsor is the Prince Consort's Shaw farm, which, curiously enough, derives its name from M. de Shawe, a Frenchman, from whom the property was purchased in the seventeenth century. It has since that date been a Royal farm, but it was greatly improved and extended by the Prince Consort. Windsor Great Park, of which it forms a part, was once a swamp; but now, as visitors to the Jubilee Show in 1889 will admit, it forms the finest pasture in the kingdom. The Shaw farm is the home of the Shorthorn herd, also of a small stud of Clydesdale horses, with the Royal champion of 1892—the Macquhae—at its head, and of a flying stock of Cheviot ewes and the noted breed of Albert White pigs. It is significant of the original state of the soil that sheep, if kept longer than one year, are liable to foot-rot; hence the Southdowns were abandoned, and an annual purchase is made of Cheviot ewes in lamb to a Border Leicester tup. These ewes, along with their produce, are simply kept for one year and fed off. The Shorthorn herd is, however, the great feature of the Shaw farm, and perhaps it has done more than any other agency to bring before the public the work of the Queen as a stock breeder. Alike at the breeding and the fat stock shows the home-bred Shorthorns from the Royal herd have done wondrously, and our plate to-day places before the eye of the reader some of the more notable of the animals recently owned by Her Majesty. The herd is managed by Mr. Tait on thoroughly sound commercial principles. The foundation was laid early in the fifties by purchases from Earl Ducie and other noted breeders. Latterly, however, it has been strongly dominated by Scottish blood, the success of the Sittyton Field Marshal being very noteworthy, and now the stock bulls are Christmas Present and Prince Victor. Clydesdales were first fancied by the Prince Consort as long ago as 1854, when H.R.H. paid 250 guineas to Mr. Findlay of Easterhill for Britain (86). The produce of that horse sold well, some of them making £100 and up to £150 a piece. At the Royal Jubilee Show in 1889 Her Majesty was first with the two-year old horse First Choice, and three years later the Royal stud horse was champion at Warwick.

The Flemish and Norfolk were in the hands of King George III., and were originally so called because they afforded ocular demonstration of the two systems of farming indicated by their names. Great improvements were made on the Flemish farm in the way of drainage and the steam farm was here shown at work during the International Show at Battersea. Here also the Royal herd of Hereford cattle is found. It was established in 1855 by purchases from the Earl of Radnor, and a bull named Brecen was purchased in 1856 for £120. The Devon herd was founded on the Norfolk farm in 1856, and the first show yard successes of the Royal herd are at the credit of the "rubies." Prince Albert first exhibited at Smithfield Club in 1843, and in 1849 he first exhibited Devons, in 1850 Shorthorns, and in 1859 all the stock exhibited were home-bred. The success of the Royal Exhibits of home-breds during the past few years has been phenomenal. No other exhibitor of stock has been as the Queen within the same period with animals solely of his own breeding. Besides pedigree stock, a large number of sheep and cattle are fed on the Flemish farm and sold off by auction at Smithfield

Invariably high prices are realized and the whole appearance of the animals bears witness to the thoroughly sound principles upon which Her Majesty's agricultural enterprises are conducted.

Whatever be the fate of English agriculture in days to come, the Royal family will be sharers in its prosperity or adversity, the bright traditions of the reign of Queen Victoria will be honoured and observed for many a day.

OCCASIONAL NOTES.

We are glad to find that there seems to be a probability of manures being manufactured locally, and, indeed, the samples which we have seen of the stuff turned out by way of trial, go to show that the art of manure-manufacture is well understood by the maker, not only as regards the regulation of the proportions of the important ingredients of plant-food, but also in the matter of disintegrating and mixing. We shall refer more fully to these local manures as soon as they are offered for public sale.

The "Cocoa dialogue" as the contribution to the last number of the Magazine on the subject of the Cocoa pest has been termed, was a distinctly valuable addition to the 'literature' on the subject. The writer of the dialogue, be it noted, has not only held the views he promulgates therein, but has practised them on his estates (which are free from the ravages of *Tomicus perforans*.) and so supplied the "Q. E. D." of later hypotheses as regards "Suckers" and the cocoa pest.

We are glad to announce that Government has sanctioned the experiment in bee-keeping referred to in our last issue, so that the stocking of the hives, which have been specially constructed for us will be undertaken at the earliest opportunity, and the progress of the new venture will be reported from time to time in the pages of the Magazine.

A sale of stock drafted from the dairy herd took place at the end of June, and the prices realized were fair. The output of milk at the dairy, which at the beginning of the year was a good deal short of the demand, has increased considerably, and the supply at present average 50 gallons a day. A new wing, to hold about 25 animals, and principally intended for the accommodation of the young growing stock, has just been added to the dairy.

Dr. Voelcker's contribution with reference to "Malt Coffee" warns us that there is just a possibility of some substitute for the genuine article springing up to compete with tropical products. Tea substitutes we have had galore, but none has succeeded in affecting to the slightest degree the popularity of our staple product, and it is satisfactory to learn on the high authority of Dr. Voelcker that there is no likelihood of there being a reversion to what is said to be an old practise, viz., the use of barley as a coffee substitute.

The suggestions with reference to agricultural education made by Mr. Davidson, in his report as Assistant Government Agent of Kegalle, are such as will commend themselves to all who have

thought over the possibilities of stimulating the native agriculture of the Island. We have ourselves made similar recommendations off and on, but in this country it is necessary to have an accumulated mass of corroborate opinion gathering to a head before one can hope to roll away the obstacles which those whose policy should be to promote the prosperity of the indigenous population by the adoption of all reasonable and tried measures, are ever ready to place in the way of advancement and reform.

WOOD ASHES.

The use of wood ashes for manurial purposes dates from a very remote period, and the chief if not the only object held in view by its use as such is to supply the potash required by plants. Whether wood ashes fulfil this requirement is another question, with which we are at present not concerned.

To some extent the composition of the ash of wood varies according to the sources from which the wood has been obtained, that is to say according to the kind of plants from which the wood has been got. It also varies according to the parts of trees used, for instance, as Warrington points out in his *Chemistry of the Farm*, the ash of young boughs is richer than that from full-sized timber. In rural districts where twigs instead of split wood are the chief kind of fuel used, we would expect to find a rich ash. In this connection we might also refer to the common use of the leaves, shells and husks of the coconut for burning, whereby a form of ashes that can hardly be characterised as "wood ashes" is produced. Dr. Falconer King, the City Analyst of Edinburgh, gives the following ratios representing the quantity of ash from different parts of plants: taking wood as 1, the ratio for other parts are, seeds 3, stem and straw 5, roots and tubers 7, bark 7 and leaf 13. As regards the composition of wood ashes, out of seventeen samples analysed at the Connecticut Experimental Station last year, the ingredients varied from 2 to 7 per cent of potash, $1\frac{1}{2}$ to 2 per cent of phosphoric acid, with an average composition of potash 5 per cent, phosphoric acid $1\frac{1}{2}$, lime 26, sand and soil 15, and charcoal 2 per cent.

But the value of wood ashes varies most according to the condition in which it is obtained, that is, according to the treatment which it has under gone after it has been produced. It is a common experience to find ashes left exposed to the sun and rain which help to materially lower its value as a potash manure. It has been found by analysis that while the potash in "unleached" wood ashes varies from 2 to 8 per cent, that in "leached" wood ashes varies from 1 to 2 per cent only. Leaching or leaching is the process by which water is made to pass through wood ashes, in order to separate the alkali in the production of lye. Now this is just what often goes on when ashes are left exposed to our tropical rains, the result of which would tend to justify the advice which we read in an American Exchange, viz., "Wood ashes should be produced on the land and should never be bought, as the price of the potash contained in them is, as a rule, far too high to justify their purchase." We would remark, however, that this applies to a

country where 45s. is asked for a ton of wood ashes. But where the stuff could be got at about half the cost, and where, moreover, it is possible to insist on the ashes being protected against sun and rain, the advice given above is not altogether justifiable.

The Connecticut Experimental Station has arrived to the conclusion that in addition to the value of wood ashes as a fertilizer, they must also be regarded as a source of lime in the form of carbonate, and is inclined to attribute their admirable effect on many soils to the lime quite as much as to the other elements contained in it.

In view of the importance attached to potash manures in scientific circles, as the result of careful experiment to estimate its value as a fertilizing agent (*vide* articles on "Potash and Potash Manures" in the Magazine), all tropical cultivators would do well to conserve, and obtain wood ashes from every available source for application to their land in conjunction with their nitrogenous and phosphatic manures.

FRUIT CULTURE.

(Continued.)

RESPIRATION OF ACTIVE ROOTS DEPENDENT ON THE MECHANICAL CONDITION OF THE SOIL.

It cannot be too strongly impressed upon the cultivator that the roots of trees are not passive occupiers of the ground, but have vital functions to perform which require the soil to be presented to them in a suitable mechanical condition. *They have to respire.* If the soil around them be so compact as to exclude air, or if it be drenched with water so as to drive the air out of its interstices and keep it out, the roots will infallibly die. In fact they can no more do without the small quantity of air they need than animals can do without the enormous supplies necessary for their more active respiration. The difference is one of degree only. The respiratory process is the same, consisting in the intake of atmospheric oxygen, its use to oxidize carbon compounds, and the subsequent output of carbonic acid. But because vegetable respiration, even from the leaves, is very sluggish, and masked from observation by the much more active work of assimilating carbon to build up the tissues, it is apt to be overlooked. And from this ignoring of a vital necessity spring some of the worst errors in cultural practice. We have enumerated certain mineral soil-constituents which must be present amidst the vast bulk of earth the planter has to deal with. It follows from the above that besides these, and in far greater bulk, there must be present *air* and *water*. The only way in which these two elements, a gas and a fluid, can be secured for the service of the roots is by breaking up the soil into a more or less powdery, porous, open condition by mechanical means. In the interstices of the separated particles of earth there enters an abundant medium of air, nearly equal in cubic measurement to the bulk of the solid matter of the soil. One may almost predict the degree of success of any crop by the degree to which atmospheric air has been mixed up with the earth it is to grow in. The traditions of agriculture unconsciously point to the same

truth. To till land is to mix the top stratum with air. Coarse ploughing of wet lands is leaving the great slab-like clods lying loose to dry out their water and absorb air instead. Harrowing among other ends, mixes air very completely with the loose tilth. But the most thorough and effective addition of this necessary ingredient is obtained by the process of *trenching*. By trenching almost every cubic inch of soil is disassociated, large cavities full of air are left open among the loosely thrown up earth, and although these diminish a good deal by pressure of the superabundant material, yet the air they contain forces its way into the microscopic interstices between particles far smaller than grains of sand.

So much for the air supply demanded by the root respiration. Let us consider the water supply. It is unfortunately the current belief that trees must have water given to them much in the same way as one waters a house. Either whole bucketsful are poured in at the base of the trunk, or (in irrigating) a stream is turned on to flood its surroundings. This is in direct opposition to the way in which trees take up their water supply. "It is characteristic of the mode of life of land-plants," says Sachs, "that they only flourish as a rule, when their roots are evenly distributed throughout a soil that is relatively dry, only partially flooded with water." The practice of agriculture bears testimony to this fact that damp lowlying lands are made highly fertile by an adequate drainage which renders them relatively dry. The culture of plants in green-houses teaches that land plants rooted in pots very easily perish if they are watered too often, and one of the first lessons a garden apprentice receives is "to keep his watering can quiet." Land plants, and particularly trees, carry on their root-functions continuously only when the soil surrounding them is relatively poor in water. A complete saturation must be very brief and soon relieved by draining away, or else it acts injuriously. Let us consider how the enormous losses of water by daily transpiration from the leaves are made good by imbibition from soil, not wet but only just perceptibly moist to the touch, and therefore in the best possible condition for sustaining healthy root-growth. Every minute particle of earth, even down to those too small for distinct vision, is enveloped in a thin film of adherent water held fast by surface attraction, almost as if it had been dipped in water and brought out wet. Where particles by reason of their angular shape happen to get closely together, the attractions combine to hold a thicker watery layer. The remaining interstices are filled with air. Among these surface-wetted particles the root hairs make their way, clinging tightly to them with their porous cell-wall and absorbing such part of the watery layer as they touch. It needs little knowledge of the laws of diffusion and capillary attraction to see that the fluid so absorbed is made good by neighbouring water-particles, and that, given absorption at any point, an indraw takes place towards it. Every root-hair then is a centre of attraction to the water constituting the moisture-layer of all particles of earth within its range. And such absorptions, multiplied by millions, amply supply the almost incredible number of gallons of water daily transpired as vapour from the foliage of a large tree.

But have these physiological facts any value in practical work? Much every way, as we shall see.

(To be continued.)

THE RECENT HORSE PLAGUE AT MANNAR.

An epizootic among horses and donkeys broke out at Mannar about the latter part of March. Only a comparatively few donkeys succumbed to the disease; but the number of ponies attacked up to the 4th May was about fifty, and of these none recovered. A similar outbreak is reported to have taken place some twelve years ago.

It is needless to say that a veterinary surgeon would have been the fittest person to investigate the nature and cause of the disease, and it is rather unfortunate that such an officer could not have been present on the spot during the outbreak. In the absence, however, of any information from a veterinarian, we have to rely on the reports of the Adigar and the District Medical Officer of the place. The report of the latter especially is very welcome, under the circumstances.

The most striking symptoms, as given by the Adigar, are that the animals begin to lose flesh, and in the course of 20 or 25 days they are reduced to mere skin and bone, fall to the ground and die.

The Medical Officer goes more into details and describes the symptoms as follows:—"Loss of appetite, great thirst, dyspnoea, constipation, restlessness, inability to walk, and when attempting to walk the horse falls down. While in the recumbent position, he shows restless movements of the limbs and body. In some cases there was no passing of dung at all, and in others the dung passed was dry and scanty. Most of the horses were found dead by the side of water-pools or ponds. Fast breathing was a very noticeable symptom."

This description of the symptoms would have been more complete had we been told whether the respiration was thoracic or abdominal, and if a record had been kept of the temperature and pulse as well as of the number of respirations, per minute, at stated intervals during the progress of the disease. Auscultation and percussion should have been helpful to the diagnosis. The nature and quantity of the urine ought to have been noticed, and the condition of the skin and mucous membrane also observed.

The postmortem examination held by the Medical Officer however gives some valuable information. He examined three carcasses and found the lungs inflamed in all of them. In the first case, except $\frac{1}{3}$ of the lungs the rest was all inflamed, and this horse died in the first stage of pneumonia. The second horse examined died in the second stage of pneumonia. The other one died in the first stage. As the result of his examination, the Medical Officer feels certain that the horses died of an epizootic form of pneumonia. It would have been useful if the pleurae were also specially examined in order to find whether they were involved in the inflammatory condition.

The Adigar thinks that the disease was caused by feeding on bad pasture. During the heavy

rains, he says, the grass on the "Tharavas" rotted under a mixture of sea and rain water, and was converted into a moss-like substance which the horses used to eat while grazing.

The Medical Officer, however, writes as follows:—"The exciting cause of this disease, I believe, is change of season,—a season of plenty of rain and pasture changing to a season of drought."

The identification of the disease is an important matter from a veterinary point of view. It is not likely that this horse plague at Mannar is a new disease which has not been described in standard works on veterinary science. I am inclined to think it is identical with what Prof. Williams calls Epizootic Pleurisy or Pleuro-pneumonia of the horse. The Professor says: "In 1861 to 1862 this form of epizootic disease became very prevalent in the north of England, where it raged for many months, committing great havoc amongst horses of all kinds, but particularly amongst those most exposed to the vicissitudes of the climate. It has prevailed more or less ever since, both in town and country, more particularly amongst young horses and those removed from pastures into stables. *** Alternations of heat and cold are undoubtedly the most prolific causes, for the disease prevails mostly when the winds are cold and the heat of the sun more or less powerful."

The treatment of this disease as recommended by Prof. Williams consists mainly of proper hygienic measures and nursing. He condemns the employment of the so-called heroic remedies such as purgatives, bleeding and blisters. Complete rest, warm clothing, comfortable housing in a well-ventilated loose box, but avoiding draughts are specially recommended by him. During the premonitory fever the animal is to be allowed an abundant supply of cold water to drink with nitre dissolved in it. Bran mashes and linseed mashes are to be given to keep up a laxative condition of the bowels, and these may be supplemented with enemas when necessary. If the alternations of the temperature of the skin be very marked, two or three doses of spirits of nitrous ether are to be daily administered in warm water. When the fever is high and the symptoms are acute, great benefit may be derived from ten minim doses of Fleming's tincture of aconite given two or three times a day. Vet. Surgeon Hayes is of opinion that the fever is of a malarious character and suggests treating it with quinine.

Opium in the form of laudanum is recommended to relieve the pain caused by the inflammation of the pleura. The laudanum is combined with moderate quantities of linseed oil so as to prevent its constipating effects.

Warm fomentations to the sides followed by the application of weak ammonia liniment will give great relief. As the local inflammation progresses the dose of nitre given in the drinking water is to be slightly increased. From one to two ounces of this salt may be given in the twenty-four hours; and when it causes excessive diuresis it must be lessened again or discontinued altogether. If, however, nitre fails to stimulate the kidneys sufficiently, a few doses of tincture of colchicum seeds will be of great service. Vegetable tonics may be given in the latter stages or during convalescence, combined with carbonate of ammonia.

If the appetite is much impaired, the horse must have an allowance of milk to drink instead of water. If the milk is refused, the animal must have gruel, linseed tea, hay tea, &c; but nothing in the shape of food must be forced upon it.

Suppression.—Prof. Williams says:—"When the character of the outbreak is mild the disease seems to be non-contagious: when violent or acute, it presents such marked signs of being contagious, that even the most sceptical is forced to believe in this method of propagation."

It is scarcely necessary, therefore, to add that, when this disease assumes an epizootic form, isolation and segregation suggest themselves as important suppressive measures.

E. T. HOOLE.

Anuradhapura, 19th July, 1897.

INSECT PESTS.

(Continued.)

It is evident that one cannot make use of preventive and remedial measures to the best advantage unless he has some knowledge of the insects with which he has to deal and of their habits. The planter or cultivator is as a rule a very busy man and cannot be expected to afford the time required for the study of the complex lines of his insect foes entirely by himself; but he should sufficiently acquaint himself with Entomology to be able to understand fully the reports on injurious insects which may be available to him. He should learn the names of his common insect foes, the characteristics of their attack and the different stages of life through which they pass, and he should confirm as far as possible the statements he reads by his own personal observations which is generally quite an essay matter, and will aid him greatly to remember about the insects. Every insect has several stages in its life and is often much more easily destroyed in a stage that passes unrecognised, because the insect then does little or no damage, than in the stage when it is injurious.

In general there are four distinct stages of existence in the life of an insect:—the egg, the larva, the pupa, and the imago. These stages may differ so greatly from one another that those who are not acquainted with insects would never suspect their relationship. Until all the stages of an insect are known, it is not possible to say with absolute certainty at what period of its life the insect may be most easily destroyed.

Such study as this constitutes economic entomology which might be defined as the study of insects injurious to the agricultural and other interests of man with a view to discovering methods for preventing or checking their ravages. As a rule such study is laborious and surrounded without difficulties. Many years of observation are often required to trace out the round of life of a single insect. Progress is necessarily slow, and even in those countries where most attention has been given to the subject comparatively few insects have been thoroughly studied. As might be expected the United States leads in the line of research. Her immense agricultural interests have forced her to it. The losses there have also been greatly in excess of any other country, owing

principally to the vast areas devoted to special crops and the importation of foreign insects.

It not infrequently happens that, owing to climatic differences, the habits of an insect in one country differ from its habits in another country. In different countries, also, the effects of certain insecticides are different, not only to the insects they are used to destroy but also the foliage. It is therefore often necessary to confirm the habits of an insect when it is found in a new country before advising means for its destruction which have proved successful in other countries, and likewise to demonstrate the efficacy of the insecticide even if the habits of the insect are similar.

BLOOD-MANURE.

We are accustomed to hear the native cultivators of the Island spoken of as conservative to such a degree that native agriculture is practically at a standstill. There are, however, instances in which the charge of conservatism (if it is nothing more) may be laid at the door of their more enlightened brethren, the planters, whether of coconuts or other products. One instance of this that has been brought to our notice is the chariness which is shown in the use of "new" manures, new in the sense that they have not been used on Ceylon plantations. Blood manure is a fertilizer that is not kindly looked on here, though next to the well-known chemical salts, sulphate of ammonia and nitrate of soda, it is the most nitrogenous manurial substance. In a (cash) price list of manures (drawn up in February of this year) which we received by a late mail, we find the following values given for the three above-mentioned fertilizers: Sulphate of ammonia, 95% pure, 20% nitrogen—£7 15s. per ton; nitrate of soda, 95% pure, 15½% nitrogen—£8 5s. per ton; and dried blood, 14% nitrogen—£7 per ton. The unit value of nitrogen in each of these manures are given as follows: Sulphate of ammonia, 7s. 9d.; Nitrate of soda, 10s. 8d.; and Dried Blood, 10s. These figures ought to convince the sceptical that Dried Blood is one of our most valuable fertilizers, and eminently suitable for perennial crops, for which indeed the two chemical salts are not.

Here is a specimen analysis of Dried Blood manure, given in the *Agricultural Gazette* of New South Wales, made by the Departmental Analyst:—

Moisture	11.30	per cent
Substances volatile at red heat	80.93	" "
Containing nitrogen	10.08

The manure is there valued at £6 15s. per ton.

In choosing manures for their nitrogen what should be done is to compare their values after calculating it out by assigning the value per unit to the nitrogen. By doing this, there will be great scope for practising economy in manuring.

Blood-manure of excellent quality is now being manufactured locally, and we believe is also being

offered much below its real value. We have heard further of a local firm that has facilities for importing dried blood, but that there will be but a poor demand for the fertilizer.

MALT COFFEE.

From a Consular Report on the trade and finance of Bavaria it appears that a considerable trade is done in that country in the manufacture and sale of a material called "malt coffee." This material is nothing more than barley grain or malted barley (more generally the former) which has been roasted and is then used either alone, as a substitute for genuine coffee, or mixed with genuine coffee, just as chicory is, to form a much cheapened article. It appears to be used as a beverage among agricultural labourers in Bavaria, and it has been suggested that, owing to its cheapness, it might advantageously be used by the agricultural labouring classes in England, and would at the same time open up a way of further utilizing barley to the benefit of the agriculturist generally as has, it seems, been the case in Bavaria. The report above mentioned states that in 1894 the sales of malt-coffee amounted to about 3,800 tons and increased in 1895 to about 5,200 tons. At the factory of Messrs. Kathreiner & Co., at Munich, 181 people are employed, and a new factory engaging 162 persons has been opened at Uerdingen on the Rhine.

Malt coffee is sold in packets of different sizes, and it is reckoned that a cup of malt coffee can be made at a cost of one-tenth of a penny.

At the request of Sir John Thorold I made a chemical examination of the malt coffee, obtaining some from Germany for the purpose. I made also extracts of this and compared it with similarly-made extracts obtained from genuine coffee and from mixtures of coffee and chicory sold in England under the name of "French" coffee and "Swiss" coffee. The malt coffee is richer in nitrogenous matters than the French or Swiss coffee, but has less mineral matter and more fibre. By analysis of extracts of these three as well as of genuine coffee, the richer character of the genuine coffee and the inferiority of malt coffee to even the other mixtures was brought out. (We omit the tables of analysis given.)

The much larger proportions of nitrogenous matters and of mineral constituents in the genuine coffee come out very clearly in the analyses the "malt" coffee extract being the poorest of all. Of course, however, the great value of genuine coffee consists in its containing the alkaloid substance caffeine, which is not present in the "malt" coffee, nor in other substitutes for coffee.

The malt coffee is ground in a mill just like ordinary coffee, cold water is then added, and the whole brought up to boiling point. The liquid is then allowed to settle, or is passed through a strainer. The malt coffee is either used alone, or it may be mixed with a certain proportion of coffee and the two boiled together with water.

No one taking the malt coffee infusion by itself would be misled into the belief that it was genuine coffee, but Sir John Thorold assures me that labourers on his estate have tried it and found it an agreeable drink. I may say that I also tried

the experiment of using it, putting at first only 5 per cent. of the malt coffee to 95 of genuine coffee, and gradually increasing the proportion of malt coffee. Though the coffee was never exactly "relished" yet, by varying the admixture very gradually, it was not until the proportion of malt coffee had reached 50 per cent. that the presence of some admixture was strongly marked.

Whether our labouring classes will be content to economise by using this material is, however, very doubtful indeed, though, on the face of it, it would appear just as good to use an article like barley as to employ chicory for mixing with coffee, the mixtures being frequently preferred to the genuine article. I am informed that the practice of making a kind of coffee from barley is not a new one even in this country, but it was given up as the age became more luxurious and the working classes better off. Nor are they I think, likely to revert to it, or to provide a stimulus to barley-growing by the hope of the extended use of that grain as a "coffee substance."—*Dr. Voelcker in the R.A.S.E. Journal.*

POTTING FIBRE.

The following is a racy and instructive report by the Government Botanist of the Cape on a sample of "potting material"—which our readers will at once identify as the patent growing medium which is now in our local markets. The report is one which our local horticulturists, particularly those who go in for horticulture, should carefully read and digest. As for the fibre itself, though there may be no new discovery about it, it cannot be denied that it is what amateur gardeners want, and, if they are willing to pay for it in the convenient form in which they can get it, well, nobody is hurt:—The potting material you send is very good of its kind, and will doubtless do excellent service in a large class of your propagating work. But there is no new discovery about it. I daresay all professional gardeners whose work has lain among greenhouse plants, have for fifty years past been accustomed to make up similar compost with coir waste, coconut fibre refuse, as it is called, with decayed sphagnum and fibrous peat. Then all on a sudden, somebody *invents* it, like a new pill made out of familiar old drugs, pushes it well and makes a good thing of it. To this commercial hanky-panky there is not the slightest objection. And such popularising of trade-processes, and making technical dodges easy for amateurs, has its beneficial side. See now, how this potting fibre business works in practice, Madame sets out her flower-stand at the window with half-a-dozen geraniums or fuchsias, purchased in high condition from the nurse-yman. She knows that plants want water, so every morning she pours the best part of a pint of it into each flower-pot with religious regularity. You know what happens in a few months. The fuchsias look ready to perish, and begin to drop their leaves; the geraniums stop growing and buckle up. Then the gardener is called in to advise. He knocks the ball of earth out of the pot, and shows Madame that all the roots have been sidling away from the earth, and have made a close network, lining the sides of the pot. He points to the soil compacted

at the surface, and perhaps covered with the first stage of moss-growth. His verdict is that the soil has gone "sour" through inconsiderate over-watering, and says the plant must be re-potted. His practice is unimpeachable—it must be done—but his theory is all abroad. What is sourness? A crab-apple is sour, last week's dough, kept over, is sour, so is some very clever people's wine—dead sour. But it is hard to see how soil, that is, earth, can be such sort of sour, since it presents no acidity to the tongue. The fact is, this gardening phrase is just a manner of speaking, a word without an idea, a flash note on the Bank of Ignorance. One mustn't let people think we don't know. And, as Mephistopheles waggishly reminded the divinity student,

"Denn eben wo Begriffe fellen

Da stellt ein Wort zur rechten zeit sich sin,"

It is just where the meaning fails that a *word* comes in so handy. Think a minute, however. The constant water-pouring has closely compacted the earth, till at the surface it is like wet mortar, and is quite impervious to air. Trickling through the mass, it has long ago dissolved out and carried down into the saucer all the soluble mineral salts required by the plant. Here are the two causes that bring about for the roots asphyxia, or stifling, and starvation. The roots have done what they could. They have crept in a white network close to the side of the pot, clinging to it because it is porous, and lets in a little air. Had the pot been glazed or made of metal, and therefore not porous, you would have had none of that stratum of root-lets trying to breathe through it. Clearly, the remedy is re-potting in fresh porous mellow earth, full of air and of the small percentage of nitrates, phosphates and potash salts which go to make up plants' mineral food, together with intelligent watering only when it is needed, or rather, keeping the soil relatively dry, so as never to drown the air out of it. So, the fuchsias and geraniums take out a new lease of life.

And I daresay the popularising of potting fibre in one form or another will bring about much better results, in amateur horticulture of the greenhouse sort, than we have been accustomed to see. The fibrous compost will stand a great deal more careless and unskilled use than would the ordinary mould taken haphazard from the borders, and on which many a window-gardener depends with touching simplicity. It is garden soil—what more would you have? So demand the unskilled. But the potting fibre will help them in spite of themselves, if they only keep their watering cans reasonably quiet, and will bear up against a deal of mismanagement. You ask as to the mineral salts that impregnate the fibre. Well, I do not pretend to tell you exactly what is used as the trade process, but if I were asked for a formula of a nutritive solution, I should give the proportions of salts which are used in experimental "water-cultures," as they are called. A mealie seed, for example, is caused to germinate at the surface of a solution of certain salts, and with proper care it will grow, blossom, and perfect its fruit. On this most interesting experimental investigation, and the knowledge it leads to, consult Sachs' "*Lectures on the Physiology of Plants*," translated by H. Marshall Ward, Oxford, royal 8vo., 1887, pp. 282-295. It will be in

your public library. The formula is about as follows:—

Water	...	7 gallons.
Potassium Nitrate (Nitre)	..	1 oz.
Sodium Chloride (Common Salt)		$\frac{1}{3}$ oz.
Calcium Sulphate (Gypsum)		$\frac{1}{2}$ oz.
Magnesium Sulphate (Epsom Salts)		$\frac{1}{2}$ oz.
Calcium Phosphate, finely pulverised		$\frac{1}{2}$ oz.

Here you have every mineral constituent required by a healthy plant, and it is fair to expect that a judicious treatment of your potting fibre with this solution, before use, will result in vigorous growth of the plants it carries. The only danger in these trials is that of being too liberal with the chemical ingredients. Remember a very little is food, a little more is medicine, and more still is poison and sudden death.—P.M.O.

GENERAL ITEMS.

The development of the coconut industry out of the Island must in time be expected to, if it is not already doing so, affect the local trade. The *Sydney Mail* of May 8th records the first shipment of coconut oil manufactured in Australia, the event being calculated by a luncheon given by the manufacturers. The mill which is turning out the coconut oil is said to have cost £60,000. Owing to the deficient supply the mill only worked 10 weeks since January when it commenced work, but during that time 1,600 tons of copra were crushed which yielded, besides a large quantity of oil, 700 tons of coconut cake, or, as we called it locally, *poonac*. The mill is about to be extended, and the orders for cake are said to be so great, that night and day work will not overtake them. The coconut cake industry is apparently a phenomenal success, owing to the patronage from dairy farmers by whom it is much sought after. The oil is being principally utilized for "sunlight" soap-making.

The attempt to introduce improved implements amongst the agriculturists of India is meeting with some success, says the Lahore paper. A new form of plough called the Baldeo plough, after Baldeo, the head mechanic of the Cawnpore Farm Workshop, is being bought throughout Northern India; it is cheap and efficient and turns out better work than the old plough. For harrows, water-lifts, and chaff-cutters, of a better type, a demand is commencing; and gradually the farmer of Northern India is awakening to the fact that the methods of

his forefathers are not necessarily the best or wisest, though they have been sanctified by the custom of centuries. So says the *Indian Agriculturist*. When, we ask, is the Ceylon Government going to give our goyiyas a fair chance of adopting improved implements in their cultivation?

As a result of experiments made with the "Baby Separator" at the Saidipat Farm, it was found that the amount of butter fat in the milk of cows kept on the College farm averaged 4.63 and 3.93 for the morning and evening milk respectively, as against 7.34 and 4.82 per cent for buffaloes' milk. The percentage of butter fat found in the separated milk was—morning yield, cows .13, buffaloes .12; evening yield, cows .13, buffaloes .17. In separating the cream the "Baby Separator" was found to act exceedingly well even with buffalo's milk, the separation, as in the case of cow's milk being, to all intents and purposes, complete.

The proceedings of the Agri-Horticultural Society of India for the months, January to March, 1897, contain some interesting correspondence relative to the Rush-nut (known to botanists under the names of *Cyperus bulbosus* and *Cyperus esculentus*), a very common article of consumption among natives of India, to whom it is known by the name of *naseru*. It comes into season during the hot months, and is then much valued for its cooling and nutritious qualities. The little black, hairy bulb, about the size of a pigeon's egg, is not pleasant to look upon; but when the outer skin is removed, there is disclosed a crisp, creamy nut, luscious, cool, and sweetish to the taste, with a pleasant flavour all its own. These nuts are rich in albumen, gum, oil, saline matters, and oxide of iron, and our Yankee friends, more appreciative of these virtues than ourselves, cultivate it on a large scale, and manufacture from it the "Chufas" coffee and "Chufas" chocolate. *Cyperus bulbosus* is the *Chilanthi arisi* of the Northern Province which is there used after grinding into a meal in times of scarcity and at other times also eaten roasted or boiled. The sedge grows freely in the Island of Delft. Its close ally is *C. rotundus*, the Sinhalese Kalanduru, which is a common weed in most parts.

The fibre of *Hibiscus Tiliaceus* (Sinhalese Belipatta), referred to in the last report of the Director of the Botanic Gardens, is one of the oldest and best known of fibres among the natives, who use it both in the rough and prepared condition as rope.

[No. 3.

“PIONEERS OF THE PLANTING ENTERPRISE IN CEYLON.”

(Second Series.)

ALEXANDER HARPER, J. P.

PLANTER AND MERCHANT:—1849—1889.

THE gentleman, whose portrait we present this month, is not one of whom much can be said; for, although an old and respected Colonist in his day and emphatically a Planting, Pioneer, he was among the most modest and unobtrusive of men, and as a relative has stated to us,—exceedingly reticent about himself. The district with which he was most identified is Matale East, where he came to own as well as manage the Mousakande Estate, before he was induced by Mr. George Wall to become a partner in his firm, and to do much of the work of visiting and inspecting the estates for which the Firm had the Agency.

But to begin at the beginning—and to give the purport of one or two slight sketches of Mr. Harper's career as put before us—we learn that Mr. Harper was born in the Parish of Birse, Aberdeenshire, of very respectable parents, his father being a man who took a firm stand for moral and religious life, at a time when evangelical doctrines and practice in those parts were rather dead. From a lawyer's office in Edinburgh young Harper came out to Messrs. Crowe & Co.,* Colombo—then interested in planting as well as import business,—and

was engaged in planting in several places. For some time he was at work in the Galle district opening coffee land, but it turned out unsuitable. After that he was connected with the old “Ceylon Plantations Co.,” in Elkadua, and then went into business with George Wall and Captain Jolly, doing generally the Visiting Agent's work when Mr. Wall was in Colombo. Mr. Harper returned to Scotland in 1862, and for four years was Captain of Volunteers, making a most efficient officer; and then in 1869 when his first wife,—daughter of Andrew Cross, Esq., Sheriff Substitute of Perthshire, and a sister of Mr. A. L. Cross, so well-known and respected in Ceylon,—died, the widower returned to Ceylon and resided till 1872 on Mousakanda Estate in Matale East. Illness compelled him in that year to leave for Europe, and he never afterwards returned to the Island. In 1874, he sold his interest in Mousakanda to George Wall & Co., and in that same year, or early in 1875, Mr. Harper married for the second time, his bride being Miss Reid, eldest daughter of the Rev. W. Reid of Banchory-Ternan, Aberdeenshire. By his first marriage, Mr. Harper had one daughter, who became the wife of Dr. Leslie Milne now of Caledon, Cape Colony, son of the Rev. Dr. Milne, Parish Minister of Fyvie, Aberdeenshire; and one daughter and son by his second wife, but the boy died in infancy.

One of the most interesting parts of Mr. Harper's life was his residence and work in Italy. After his second marriage he resided a

* Better known as Messrs. Crowe, Crabbe and Christian in the “forties” until Mr. Christian joined Messrs. J. M. Robertson & Co. and Mr. Crabbe returned to London, when the firm became A. & R. Crowe & Co.—Ed. T.A.

few years in Edinburgh, and then in 1879 he and his family went to Rome and passed the winters there till 1884, when Mr. Harper bought a small property "Torre el Praeto" near Florence, and spent the rest of his life there save for occasional visits to Scotland. Mr. Harper was much interested in agriculture in Italy, and began to pay special attention to the cultivation of Olives and Vines; but his health failed, and after a trying illness of five months, he passed away in April 1889.

Physically, Mr. Alexander Harper was one of the many fine strong young men that came from Aberdeenshire in the "forties and fifties." He has told Mr. A. L. Cross that when he first arrived in Ceylon, he could fell forest alongside of the very best Kandyan axemen; and so active did he continue in his habits that when he became a Visiting Agent he would often turn up at estates 20 miles from Kandy, while the Superintendent was preparing to muster his coolies in the early morning.

To the last his interest in Ceylon was warm and deep, though there can be but few in the Island now who can recall the tall manly form of the late Mr. Alexander Harper. One hears a great deal in the present day of Social Brotherhood; but we fancy (from all we have heard—not from himself of course, but from others) of Mr. Harper's good deeds, that there have been few men who made it more their aim to keep the helping hand always outstretched than the late Mr. Alexander Harper:—

'Tis ever wrong to say a good man dies.

Agricultural Pests :

WITH METHODS OF PREVENTION,
BY MISS E. A. ORMEROD

(LATE CONSULTING ENTOMOLOGIST TO THE
ROYAL AGRICULTURAL SOCIETY OF
ENGLAND.)

(Concluded.)

VIII.—LIVER FLUKE, &c.

Slugs are injurious to almost every kind of crop. They belong to the division *Mollusca*. The true slugs may be generally described (when extended or in movement) as being long, more or less spindle-shaped, cylindrical or tumid, head prominent, "tentacles" (commonly known as horns) four in number, and two eyes placed on the tips of the uppermost pair of horns. When at rest or alarmed they draw themselves together into a lump. The field, or milky slug, *L. agrestis*, is a somewhat spindle-shaped kind, about an inch and a third long, grey in colour, and with milky slime, and is very common. The *Arions*, or black slugs, are distinguishable by the skin being wrinkled, and the shield on the back shagreened. *Arion ater* is as much as four inches long. The colour of these two kinds of *Arions* is very variable, and they are stated to lay their eggs separately under ground.

One very important point to be considered in methods of prevention is the circumstance that the slug can exude slime, so that it can "moult off," as it were, a coating of lime, or other obnoxious dressing thrown on it, and thus (quite getting rid of it together with the slime) be no worse for one application of any ordinary dressing. This moulting the slug can do a few times successively, but after the operation has been repeated two or three (or at least a very few times), the creature requires an interval to regain the power; the slime reservoirs, or power of exuding slime, are exhausted for the time being, and the obnoxious dressing consequently takes effect on the skin of the slug and kills it.

Where there is bad slug-attack in fields, attention is particularly needed to these points. On unoccupied land, such a heavy dressing of gas-lime, or quicklime or salt, may be put on, that wherever the slug crawls there is the obnoxious stuff, and it soon loses its slime-producing power and perishes. But very often, where crops are infested lime is only thrown in the middle of the day, or at any convenient time, just when the slugs are sheltered from the dressings falling on them, and as it soon slacks it does very little towards getting rid of the infestation. I have seen the slug resting as comfortably in the slacked lime as it would under a stone. Or again, if one dressing is given in the morning, or when the slugs are out at feed, it often happens that it is not followed up by another before the slugs can protect themselves. To do good the dressing should be thrown in the evening, when the slugs are at feed, and again the following morning. If the slugs should re-appear next evening, the dressing should be given again; but if it has been properly applied, probably there will be no need.

One or more kinds of the marsh, or water snails play a most seriously injurious part as "hosts" of the liver fluke of sheep, during the early stages of its life. The *Limnaeus truncatulus* is the kind which is especially recorded as infested by the fluke in its early stages. Regarding presence of infestation in the *L. pereger*, there has been difference of opinion. These marsh snails wander about, and both kinds are nearly amphibious; they may be found in damp grass as well as in pools.

During the years in which I had personal knowledge of habits of *Limnaeus* at Sedbury Park, in West Gloucestershire, *L. pereger* was excessively prevalent in small field ponds or drinking places, where floating water plants, weeds round the bank, and more or less mud, according to weather or season, gave every encouragement to their increase; but we only met with the *truncatulus* in one of these small ponds. It would have been of considerable scientific interest (if we could have had technical examination by an expert) to find whether, in circumstances so congenial to *pereger*, the fluke infestation was perfected in it up to maturity, which it does not appear to reach in this species of snail, as observed in captivity. But, as a coincidence at least (whether of this, or of great amount of rabbit presence), our sheep were constantly affected by rot to so serious an extent that it was stated by the bailiff he "never killed one with a sound liver." Neither snails nor flukes are connected with insect life, but this one parasitic attack is given in some degree of detail as an example of the very different successive forms which some of our farm infestations go through, and also of the very different localities in which they are to be found during their progress to maturity.

The following information is abridged from the history of the liver fluke, recorded from his own observations by Prof. A. P. Thomas.—"The liver fluke, *Fasciola hepatica*, lives in livers of various vertebrate animals, and, in this country, especially of sheep, as well as of rabbits and hares; it averages from about an inch to an inch and a quarter in length, and in shape may be described as not unlike a little sole, in width about half its length, flat, and largest towards the head end. At the tip of

its head part is placed the mouth, in the middle of small sucker, and at the point where the head joins the flat body, on the lower surface, is another sucker. The colour is pale brown. The eggs, which are brownish and excessively minute, are passed down from the liver to the intestines, and thus distributed with the droppings of the infested animals. If the eggs fall in favourable circumstances for hatching (that is, warm weather on wet and marshy ground, or are washed into ditches or ponds), the embryo within develops in a period which may be of from two or three weeks to two or three months, according to temperature; then the contained embryo pushes off one end of the egg-shell, and swims away with great rapidity and activity. This embryo is described by Prof. A. P. Thomas, in his minutely recorded observations from life of this infestation, as being only about 1-200th of an inch in length, that is, almost too minute to be visible to the naked eye, and in shape not unlike a sugar loaf. In the centre of the largest end is a peg-like projection which is used as a boring tool, and can be withdrawn, or greatly thrust out, at pleasure. The embryo darts and circles about in the water, large and foremost, and if, in the course of its movements, it meets with the water snail (*Limnæus truncatulus*), it at once commences operations. It inserts its borer, and, spinning round and round on itself in the water so as to work the point in like a centre-bit, squeezes its way into the substance of the snail. Here the embryo settles into almost still life, and changes into an oval form, which, when complete, is known as a sporo-cyst, that is, a "cyst," or a bag or bladder, of germs. Within this bag, so to call it, about ten germs develop, known as "redia." Each redia as it is developed makes its way out of the sporo-cyst, and being furnished with a mouth and intestine, and two projections that answer the purpose of legs, it feeds on, and makes its way about within, the body of the snail.

Up to this point it will be seen there are four distinct stages of fluke life—the egg; the free swimming embryo; the quiet form of the sporocyst, altering to a mere bag of developing germs; and the germs called redia, free from the bag, and feeding on the snail, which ultimately (for the most part) sinks under the parasitic attack. Continuing the history from the same observations, it is shown that in each of these redia there form (as in the sporo-cyst before mentioned) a number of germs, but different to these in shape. The germs (the redia) that formed in the sporo-cyst are long and narrow, about the sixteenth of an inch in length, and about one-fifth of their length in width; but the germs which form within the redia are exceedingly like tadpoles, being oval and flat, and furnished with long slender tails more than twice the length of the body.

These "fluke tadpoles," so to call them, are technically called cercaria, meaning animals with tails. On the escape of each cercaria from the redia in which it was formed, it makes its way from the body of the snail into the water (if in a pond or ditch), but shortly attaches itself to water plants, or whatever may be accessible. There it draws itself up into a round ball, exudes a gummy secretion, wags its tail violently, till at last the appendage, which has now ceased to be useful, is thrown off, and the gummy substance hardening, the cercaria remains within the covering as a little white spot on the plants, or on the locality to which it has attached itself. It is mentioned, however, by Prof. Thomas that "if the infested snails are crawling on the margin of a ditch or over a damp field, the cercaria, on leaving the snail, at once proceed to form their envelopes or cysts at the bottom of the grass, and so attach themselves to the stalks or leaves near the roots." The next step completes the circle of infestation. When the grass, to which the white speck-like cysts containing the young liver flukes adhere, is eaten by the sheep, or other suitable hosts (as rabbits or hares &c.), the young fluke comes out of the covering, and passes to the liver

of its host, increasing in bulk, after being swallowed, from about the eightieth of an inch, to the adult length of an inch or an inch and a third.

Amongst methods of prevention and remedy mentioned by Prof. Thomas are the following:—

Care must be taken to avoid introducing eggs of the fluke either with manure, or with fluke sheep, or in any other way. Rabbits and hares must not be allowed to introduce the eggs.

Dressings of lime, or salt, should be spread over the ground at the proper seasons, to destroy the embryos, the cyst of the fluke, and also the snail, which acts as 'host.'

Sheep must not be allowed to graze closely, for the more closely they graze, the more fluke germs will they pick up.

When sheep are allowed to graze on dangerous ground, they should have a daily allowance of salt, and a little dry food.

Amongst the details of treatment, of which the above is an abstract, is the observation:—"The freedom from rot of sheep feeding on salt marshes is well known, and is now shown to be due to the poisonous action of the salt on the embryos, sporo-cyst, redia, cercaria, and cyst, and to its similar action on *Limnæus truncatulus* itself. Even a weak solution of salt in water (containing only $\frac{1}{4}$ per cent. of salt) proves fatal to this snail.

This principle of prevention would be especially applicable where (as in the instance, before mentioned, in West Gloucestershire) it was the custom to have exceedingly small ponds or cisterns of mason work open to the field on one side and very shallow, and only a few yards square. From the immense quantity of weed or grass growth in or at the edges of these so-called "cattle-drinks," and sometimes the quantity of mud (which is stated to be the especial place of deposit of spawn of the *Limnæus truncatulus*), there was every circumstance that was good for shelter, or propagation, of either *truncatulus* or *preger*; and in circumstances like these a very small outlay on salt would carry destruction with it to the snails and the fluke embryos in the water. Clearing the various vegetable trash, and sprinkling some salt on the mud and into the water, would cost little, and from the details given would, in many cases, strike *in embryo* at infestation which presently, when dispersed over the field, would be far more difficult to deal with.

THE END.

ARECA-NUT CULTIVATION IN INDIA.

IN THANA.

The betel-nut is grown largely in Thana, Bombay. The best nuts are carefully selected in October, and dried in the sun; unhusked nuts are considered best for seed. They are planted in a well-ploughed plot of land in pits three inches wide and three inches deep, and at a distance apart of from six inches to a foot. For the first three months the young palm is watered at least every fourth day, and afterwards every third day. When the plants are a year or a year and-a-half old they are fit for planting out.

The selling price of young plants varies from 6 pies to 1 anna.

The betel palm usually grows in red soil, but it flourishes best in sandy soil that remains moist for sometime after the rains. Before planting the young palm, the ground is ploughed, levelled and weeded, and a water channel is dug six inches deep and a foot and a-half wide. The pits 9 inches deep and two feet wide are dug at least four feet apart, nearly full of earth, but not quite full, so that water may lie in them where the soil allows; plaintains are grown in the beds to shade the young palms. Except during the rainy season, when water is not wanted, the young trees are watered every second day for the first five years and after that every third or fourth day. During the rains the manure is sometimes given.

The cost of betel-nut cultivation in Thana is calculated as follows:—An acre entirely given to betel palms would, it is estimated, hold 1,000 trees. The

total cost of rearing 1,000 betel palms for five years—that is, until they begin to yield—is about £127. 13s., including compound interest at 9 per cent. After five years a thousand trees are estimated to yield about £50 a year, from which, after taking £18 14s. for watering assessment and wages and £11 9s. 11½d. as interest at the rate of 9 per cent on £127 13s., there remains a net estimated profit of £19 16s. 3½d., or 15.52 per cent.

IN BENGAL

The supari, or betel-nut is common in Eastern Bengal, especially in Tipperah, Backergunge, and Dacca; and its cultivation is very profitable to proprietors of land. It bears fruit in the eighth year, and is most productive from that time to the sixteenth year, when the produce falls off. The nuts are gathered in November.

Betel-nut cultivation is very extensive, especially in the Police circles of Tubbikigara and Hajigunge. A considerable trade in this article is carried on with Dacca, Naraingunge, and Calcutta. The cultivators of the palm usually own a large piece of ground, slightly raised above the level of the surrounding country, and surrounded by ditches. In the centre of this they build their dwellings, and all round them they plant betel-nut trees. An acre of land will obtain about 3,000 trees. When first planted the betel-nut requires to be protected from the sun; for this purpose rows of madar trees are planted between the lines of betel-nut trees, and the growth of jungle is encouraged. When the betel-nut trees have grown strong, and no longer require the shade, the cultivators are too lazy and thoughtless to remove the jungle; and the result is that whole pergunnahs which were once fully cultivated are now covered with dense jungle, in which even the betel-nut trees cannot grow; while thousands of the inhabitants have been swept away by cholera and malarious fever of a very virulent type. The unhealthiness of the neighbourhood of betel-nut plantations is variously attributed to the dense jungle and under-growth above mentioned, to the exhalations from the trees, and to the malarious gases generated by decomposing vegetable matter in the ditches surrounding the plantations. The betel-nut trees grow to a height of about 60 feet; and in some pergunnahs they are cultivated to such an extent as to almost entirely exclude rice cultivation.—*The Indian Agriculturist.*

PLANTING IN JAVA.

TEA—ARABIAN COFFEE—LIBERIAN COFFEE.

We mentioned lately that the M. M. steamer "Oceanian" brought back to Ceylon, after a visit to the Straits, Mr. John W. B. Davidson, engineer of Messrs. Walker, Sons & Co., who set out in May last, chiefly with the object of doing business for his firm in the way of supplying coffee machinery to the planters in Java. Leaving here by P. & O. steamer in May, he made no stay at Singapore, but took the first steamer to Batavia, which he reached on the 27th of May. From Batavia he visited the tea districts, situated at an elevation of about 3,500 feet, and which are reached by means of a narrow-gauge railway in three hours. This railway he describes as very suitable to the needs of the country and the trains only capable of improvement in being furnished with a refreshment car, as the Ceylon trains are, instead of the refreshment arrangements being confined to a few stations on the route. His halting-place was Tjiwangic estate, a place of over 1,600 acres owned by a company, but having an Englishman, who is a part proprietor, in charge. Here he made his headquarters, and, going round the district, he says, he saw

TEA THAT SURPRISED HIM

very much indeed. "The growth and appearance of the bushes," he remarked, "were a great way ahead of anything I had seen in Ceylon at that time; in fact, tea 18 months old was something similar to the tea here three years old. The soil was far superior to the Ceylon soil, and they do not bother about weeds,

and neither have they to manure. I must say I am rather surprised that more Englishmen do not go there, for there are only two Englishmen in the place that I know of, and they are keen on getting some of their fellow-countrymen there. I suppose I visited nine or ten estates in that district—all good, and furnished with well-equipped factories. Their process of manufacture is not like ours; they do not go in for withering to the same extent that we do, their tea being sun-dried, which entails a lot of work, and does not give good results. A fair proportion of the tea I saw was in full bearing.

ARABIAN COFFEE.

After leaving there I went to the East of Java, where there is nothing grown except Arabian coffee. This part is where Mr. Turing Mackenzie is, but I did not meet him, and only made a short visit there.

LIBERIAN COFFEE.

I next went to Samarang, where there is a great deal of Liberian coffee planted, and I saw it in various stages of growth, and noted that there was a great deal of disease amongst the trees. I also saw a quantity of cocoa; but this year's crop is an utter failure, owing to disease. I rode through a great many miles of coffee, planted by Government, which struck me as a novelty. The Government there plant up coffee, and what they grow is gathered by natives and pulped in the native villages. While going through the same district I saw some very fine teak forests. The Government goes in largely for planting teak trees, and lets out the forests to different people after the trees are in condition for felling. It was all beautiful teak wood. Then I returned to the tea district again, and visited one or two of the estates I had not previously seen, and then returned to Ceylon, having given up the idea I had of visiting Sumatra, and having practically also abandoned, for want of time, my visit to other parts of the Straits, though I called at Penang on the way down. Liberian coffee in Java is in a bad way at present, owing to low prices, as it barely fetches half what it did last year. Only the really first-class estates are maintaining the old high prices, and there is a great deal of disease about. Those who have Arabian coffee are still getting good prices, and there is some very good Arabian coffee in the place. I saw some over 100 years old and still bearing fairly well; but Liberian has gone down in price, and the disease trouble cannot be accentuated too much.

Mr. Davidson added that, professionally, his trip was a success, and his firm will be occupied for some time yet in executing the orders he brought back with.—Local "Times."

FEVER IN PLANTS.—Mr. H. M. Richards, who has previously studied the effect of wounds on plant-respiration, now describes (*Annals of Botany*, xi, 29) a course of experiments on the evolution of heat by wounded plants. He finds that accompanying the increased rate of respiration is an increase in the temperature of the parts affected. A kind of fever supervenes, and as in the case of respiration, the disturbance runs a definite course, and attains its maximum some twenty-four hours after injury. It is interesting to note that the attempt to rally from an injury is accompanied by somewhat the same symptoms, increased rate of respiration and evolution of heat, in plants as in animals. Owing to the nature of the case the re-action is less obvious in the former than in the latter, and a delicate thermo-electric element was required to appreciate the rise in temperature; but compared with the ordinary temperature of plants in relation to the surrounding medium, the rise after injury is "as great, if not greater than in animals." The maximum in all the plants investigated was between two and three times the ordinary excess above the surrounding air. Potatoes proved the most satisfactory objects for experiment, and it was found that in massive tissues (such as Potatoes or Radishes afford) the effect of injury was local, whereas in the case of leaves (e.g., Onion-bulbs) a much greater extent of tissue was sympathetically affected.—*Natural Science.*

OUT WITH THE INDIA-RUBBER GATHERERS.

INDIA-RUBBER: ITS COLLECTION AND CULTIVATION

IN NICARAGUA.

By ROWLAND W. CATER.

AT or near the mouth of all the large rivers on the Mosquito Coast will be found the bungalow of a trader, generally English or American, fitted up as a shop, and stocked with cloth, tinned and other provisions, rope, tobacco, rum, gunpowder, and similar necessities. When the unsophisticated Indian from the interior has collected a canoe-load of Jungle-produce, such as rubber, vanilla beans, sarsaparilla, herons' feathers, gold, deer, Jaguar, and puma skins, &c., he pays a visit to the trader, and an exchange of commodities is promptly effected. Hard cash plays a very small part in these transactions. In due course the merchant ships the produce to New York or London, reaping a profit of—I am almost afraid to say how much per cent.—two or three hundred perhaps. At any rate the trader speedily makes a fortune large enough to recompense him for his banishment from some more civilised country.

Many of these merchants are large employers of labour in the shape of mahogany cutters and rubber collectors. The men, Indians and Caribs mostly, bind themselves to a patron for a certain period and become practically serfs. The laws regulating these 'mozos matriculados,' as they are called, are very severe and strictly enforced. The patron or master supplies provisions, implements and perhaps a small sum of money in advance, and each mozo is constrained to be diligent, and to return with the fruits of his labour at the expiration of the term. Rubber gatherers (huleros) are obliged to deliver one half of their caucho to their employer and to sell him the remainder at the current market price, less the value of the provisions, &c., previously advanced. But the patron almost invariably keeps a shop. He does not pay for the huleros' share of the rubber in cash, but mostly in goods. Consequently all the evils of the truck system are rampant.

A large proportion of the rubber exported from Nicaragua comes from the Prinzapulca district. At the mouth of the Prinzapulca River—called Apulca in some maps—there is a village where scarcely a week passes without the arrival or departure of huleros, and there I found myself during my travels on the Mosquito Coast. My host was one of the principal traders, an American, whom I will call Hayes. In his employ were many rubber collectors, so that I experienced no difficulty in making arrangements to accompany a gang into the interior. This comprised six men, four Mosquito Indians of pure blood and two Caribs of negro type.

We started at daybreak in the usual frail dug-out, and at nine o'clock the following morning reached the point from which the huleros intended to take to the woods. Disembarking, we concealed the canoe in a sedge thicket, and after a meal of boiled rice and salmon, set out across a sandy plain in the direction of a coneshaped hill. José, one of the Caribs, informed me that the rubber trees are usually found in groups of twenty or thirty, and that he had often travelled for days together without discovering a single one.

'Dis time, sah,' he added, 'we go straight to big lot. See dem long time ago.'

But José was unaware of what the elements had in store for us. A belt of forest intervened between the plain and the hill which was our landmark. I noticed pine trees, cedar, oak, and mahogany, interspersed with wild cherries and cacao, ceibas, or silk-cotton trees, and here and there a guayava, not unlike an apple tree, but with more foliage. This is the white guava, from the fruit of which the famous jelly is made. It grows to a height of twenty feet, and is to be found in many dry jungles as well as in almost every garden or patio. The apple-

shaped fruit is a little larger than a hen's egg, smooth, and somewhat resembling a small lemon when ripe. Inside is an aromatic pulp full of small white seeds. The red gava of the West Indies is more acid and less agreeable.

We had cut our way through some miles of this forest, and had just reached a part where the undergrowth and creepers were less dense, when one of the Indians stopped suddenly and uttered an exclamation. A peculiar sound, between a moan and a sigh, was creeping through the woods; the tops of the trees were in motion.

'Huracan, señor!' shouted the Indian in a tone of alarm, and all set off running as fast as they could.

I followed, buffeted by branches and climbing plants, and torn by thorns at every step. It was a desperate race to get into the open and out of danger before the dreaded hurricane should overtake us. In speed I was no match for those practised woodmen. They left me behind. The forest swallowed them up. But I could hear their shouts and the crashing of bushes as they tore their way, and I struggled on until I could run no longer. In a cleft of a big rock on the outskirts of the wood I crouched and waited for the storm to pass.

It came quickly. The murmur swelled to a roar. The sky grew black almost as night. Branches and twigs fell in showers. Great trees bent and swayed as reeds, groaning like giants in torture. Soon crash followed swiftly on crash as the older monarchs of the forest were swept down. Some, stripped of every branch, defied the fearful blast, comparatively safe in their nakedness. Others were torn up entire, and carried yards away from the great pit their roots had left behind. But while the tornado raged, even if I had dared to look out from my place of refuge, it would have been impossible to distinguish anything, except perhaps when a flash of lightning revealed the hurtling mass of leaves and branches overhead and all around.

As suddenly almost as it came, the hurricane swept onward and passed, followed in its course by myriads of twigs and small boughs, drawn forward it seemed by suction. For long afterwards these floated in the direction taken by the storm, resting apparently on the thick cloud of dust which seemed to reach from the ground to the tops of those trees that had withstood the storm.

No hurricane so terrific had visited Central America for many years, but luckily it was confined to the coast. Adjectives are of small use to describe its effects. These provided the Indians with a topic of conversation for months, and very marvellous were some of their stories.

An old man walking beside a river was said to have been lifted up and deposited on the opposite bank. An Indian who had lost his horse discovered it in the fork of a tree thirty feet from the ground, and was compelled to fell the tree to recover it. Whether it remained sound in wind and limb the more or less veracious chronicler omitted to state. Another found in his garden a row of banana trees which he had not possessed before. Great was the mystery until the owner of an hacienda many miles away identified them as his property. Some of the tales might be true—*Quien sabe?* Nobody is obliged to believe them. But I can testify that the hurricane was a very bad one, as also do the many wrecks remaining to this day on the beach near the mouth of the Prinzapulca and other rivers.

Pushing on over the debris, I eventually reached the hill, and there found the huleros, who had sheltered in a cave with which they were acquainted.

From the hill-top the keen-sighted fellows marked down several clumps of rubber trees not in the track of the hurricane and set out in couples to tap them. I accompanied José and Pete, the Caribs, both of whom spoke English after a fashion of their own.

Here I should observe that the best and purest rubber comes from the great forests intersected by the Amazon and its many branches. It is known

as Pará rubber, and is obtained from several species of Hevea. The India-rubber plant of our green-houses is *Ficus elastica* of India, generally epiphytic, the seeds germinating at the top of forest trees, whence are sent down numerous aerial roots. Rubber, or caoutchouc as it is called commercially, is also obtained from species of Manihot, Landolphia, Willughbeia, &c., in addition to the subject of this paper, the *Castilloa elastica* of Mexico and Central America.

The *Castilloa* grows to an average height of sixty feet, and throws out its huge branches, many of them a yard in diameter, at a considerable elevation. The bark is of a dark slate or ash colour; the leaves measure from ten to eighteen inches long, are elliptical, glossy, closely veined, and paler beneath than above. They usually grow at the end of the boughs in compact groups of three. The fruit consists of a capsule comprising three divisions, each containing a large seed, white, irregularly marked with black.

The best season for tapping is from August to February; and the operation should be performed early in the morning, before the daily rain, or in the evening after the rain has fallen. In the latter case the milk should be coagulated as soon after sunrise as possible next morning.

The milk, or sap, is white, and of the consistency of cream. The tree thrives best in moist but not marshy forests on a warm sandy clay. It seeds in the tenth year, and ought not to be tapped before its eighth year, or its growth may be much retarded.

On reaching the group of trees, which numbered seventeen of various sizes, my Carib friends first cut away the twining creepers that almost hid the trunks, and then carefully removed a couple of bunches, natural ropes of rubber, formed in the following manner. From incisions in the bark, possibly caused by woodpeckers or some insect, the juice often exudes, trickling down the trunk, in and out of the encircling creepers, and sometimes reaching the ground. The milky stream coagulates and turns black as it runs, forming a long strip or cord, with which the huléros often tie up their bales.

The parasites removed, Pete and José strapped on their *aspuelaa* (climbing spurs), fastened at the knee and ankle, and having dug a small pit or basin at the foot of each of a couple of trees, passed a ring of stout rope round the trunks and their own waists, and walked up with their machetes between their teeth. By lifting the rope at every step they were enabled to stand almost erect, and when lying back in the ring both hands were at liberty.

José, whom I watched closely, commenced operations immediately before the first branch. With his broad-bladed sword he cut in the bark a horizontal canal which almost encircled the trunk and terminated in a V-shaped angle. From the point of the V downwards he next cut a perpendicular canal about two feet in length, which joined another horizontal channel ending in a V, and so on to the ground. In the last cut he inserted a large green leaf to serve as a funnel and guide the milk into the basin.

The Brazilian rubber collectors always place a receptacle of tin or earthenware in the hole at the foot of the tree to prevent the admixture of grit or other foreign matters; they also strain the milk through coarse muslin; hence the greater value of Pará rubber. But Nicaraguan methods are primitive.

The sap runs down the incisions to the basin, where the water evaporates. Artificial heat is employed to hasten this evaporation in Brazil, but happy-go-lucky Nicaraguans leave the process to nature. When the huléro is of opinion that no water remains, he makes a decoction of liana vines, or of a kind of couvolvulus, and adds it to the juice in the proportion of one pint of the former to a gallon of the latter, when the sap immediately coagulates and forms india-rubber.

When the sap had ceased to run, my Carib companions ought to have filled up the canals carefully with mud or clay. There was a stream close at hand, but they did nothing of the kind. Consequently, when next they passed that way, the trees would

probably be dried up and sapless. It is said that a kind of wood-leech attacks the tapped *Castilloa*, introducing itself through the channels, and so injures the tree as to cause its eventual decay. This the clay would prevent, and at the expiration of six months the tree might be again tapped, with as much profit as on the first occasion. I took José to task on the matter.

'Plenty huléro heah, sah,' he answered, grinning. 'Me find ten—twenty mo' trees while 'um doin' dat. Ah' what good? Perhaps I ueber come heah no mo.'

To that I had nothing to say. The forests are No Man's Land, and another huléro would probably have reaped the fruit of his labour.

The heated air speedily evaporated the water from our rubber milk, and the necessary coagulation did not occupy much time, though the process appeared to me very wasteful. With this I will deal presently, however. While the evaporation was taking place other trees were being tapped. When the sun sank the Caribs left off work. We slept beneath the rubber trees, as is the huléros' custom. All the day following the Caribs toiled, and at sunset we returned to the dug-out, José and Pete carrying about forty pound of rubber each. The Indians, who had been less successful, were awaiting us. Next morning we ascended the river still farther and again entered the forest, leaving two men with the boat to take care of the rubber and pack it in bales.

Dishonest huléros frequently put stones and pieces of heavy wood in the middle of the bales to increase the weight. But the merchant usually pierces every package with a sharp-pointed steel rod, so the rogues seldom escape detection.

At the expiration of ten days, being then four days from the mouth of the river, we commenced the return journey, towing the bales of rubber behind the dug-out. We did not escape the usual capsize; but as each man had a life-buoy in the shape of a waterproof bag, and, besides, could swim like a fish, nothing more serious than a wetting resulted, and that we could not avoid on land.

These rubber bags, which a native of this coast is seldom seen without, are made by the huléros as they go along, so to say. A sack of unbleached calico is stretched on the ground, and painted over with rubber milk, a coconut husk serving for a brush. When the first coat is dry the operation is repeated, three coats being necessary before the bag is fit for use. The result is a waterproof article, rather heavy, but in every other respect far superior to any manufactured in Europe. Before setting out in their trail canoes, the natives take care to inflate their bags and tie up the mouth. Thus the sack forms a receptacle for clothes, a pillow on land, and a life-buoy in the event of an accident upon the water.

On arriving at what was left of Mr. Hayes' bungalow, for the hurricane had not spared it, I had several discussions with that gentleman in reference to the practical cultivation of *Castilloa elastica*. The result of my inquiries on the Mosquito Coast and in other parts of Nicaragua are here summarised.

The subject has been ventilated by many private persons in addition to the various Central American governments, and in Nicaragua a bounty of ten cents native currency is paid for every tree planted. As the world's supply is rapidly diminishing, while the demand is increasing by leaps and bounds, there appears to be a magnificent field for Englishmen with capital. Certainly, unless the output is soon increased, manufacturers of rubber goods may have to fall back upon substitutes. In Mexico there are English and American Companies already at work, but, except two plantations in the Chontalcs district, I am not aware of anything of the kind in Nicaragua. That the industry would be exceedingly profitable has been demonstrated by the results of many experiments; and when I say that neither coffee, tea, cocoa, sugar, bananas, indigo, nor hemp growing would pay so well as the cultivation of india-rubber

trees, I speak on the authority of Mr. Hart, F.L.S., of the Botanical Gardens, Trinidad.

In March of last year I visited a plantation in Chontales, which, strange to say, is the result of native enterprise. It then comprised one thousand trees, well developed, of hardy appearance, and as large as a good-sized apple tree. An early maturity seemed assured.

Señor Romero, Mexican Minister to the United States, in an article published in the *India-rubber World* (New York) for April 1892, estimates that each sixty-year-old tree, planted at intervals of fifteen feet, will have cost eight cents U.S. currency, and will yield six pounds of rubber. Other authorities fix the yield at maturity as high as fourteen pounds of rubber. It depends on whether the season has been wet or dry, and whether the trees are well or badly cultivated.

In order to be on the safe side, I propose to estimate the cost to the end of the eighth year at 18 cents U.S. currency, or 9d. per tree, and the eighth year's average yield at five pounds of rubber. The market price of good Central American rubber is 2s. 4d. per lb. Para rubber fetches from 2s. 3d. to 3s. 6d. per lb.; and if gathered and coagulated in the same cleanly manner, rubber produced in Nicaragua should be worth as much. Nevertheless, I prefer to estimate on a selling-price basis of 2s. per lb. only. The result at the end of the eighth year of an acre plantation comprising 193 trees planted fifteen feet apart would be as under, including the premium of ten cents native currency—say 3d.—per tree paid by the Nicaraguan Government.

Dr.	Cr.
Cost of cultivation for the term of eight years, with seed, &c., of 193 trees at 9d. each.....	Government premium of 3d. per tree.....
£7 4 9	£2 8 3
Cost of tapping or harvesting.....	Yield of 193 trees at the end of the eighth year—965 lb. at 2s. per lb.....
3 0 0	96 10 0
To balance.....	
88 13 6	£98 18 3
£98 18 3	
Profit.....	£88 13 6

I arrive at the cost of tapping, or harvesting, in the following manner: A hulero, working in the dense, overcrowded forest, can tap four wild, creeper-grown trees in a day; therefore it stands to reason that, in a plantation where the trees are weeded and cleaned of all superfluous growth, he could tap five at least, and also plaster up the cuts with mud. Thus the 193 trees would occupy him 39 days. A mozo in Nicaragua is well paid if he earns fifty cents native currency, or say 1s. 3d. per day, but I have calculated his daily wage at rather over 1s. 6d.

Supposing that the plantation comprises five hundred acres, then, on the above figures, the eight year's profit would amount to the enormous sum of £14,337, 10s. And the yield increases every year, with no outlay except for weeding and harvesting.

The gross capital expenditure for the eight years I estimate as under:

Cost of 500 acres of land at 5s. per acre.....	£125 0 0
Surveying and procuring titles thereto.....	100 0 0
Clearing land for planting.....	1000 0 0
Collecting seed and planting.....	500 0 0
Eight yearly weedings at £200 each.....	1600 0 0
Extras, implements, &c.....	300 0 0
	£3625 0 0
Interest on £3625 for eight years at five per cent. per annum.....	£1450 0 0
Planter's expenses, cost of living, &c., for eight years at £200 per annum.....	1600 0 0
Cost of gathering the eighth year's crop.....	1500 0 0
	£8175 0 0

I have included in the above the cost of maintaining the planter during the eight years that should elapse before the Castillos are tapped; but it

should be borne in mind that when the trees are planted fifteen feet apart, coffee, sugar-cane, cotton, cacao, and other shade-loving plants, yielding yearly crops, may be grown between them, and their produce should maintain the planter. But adding five per cent. interest, the planter's expenses, and the cost of harvesting, there still remains a net profit of £36,162, 10s. Estimating the value of the ninth year's yield at £50,000, and deducting £200 for the annual weeding, £1,500 for the cost of harvesting, £180 for interest, and £200 for the planter's expenses, the net profit for that year will amount to £47,620, which is a pretty good return for a net capital outlay of £3,625. Of course it will be necessary to maintain a nursery of young plants to fill vacancies caused by accidents and replace trees when their rubber-bearing life is over; but the cost of such a nursery would not be great. And one must not count on the Government premium being paid in perpetuity.

In reference to the life of a rubber tree and its increasing productiveness, the following extract from *The World* (New York) of 21st August 1892 will be of interest:

'Three young trees transplanted from the forest to a cultivated field in Soconusco, Mexico, are now said to be seven feet in diameter, and have yielded rubber for more than thirty-five years; the present product averaging more than fifty pounds of gum per year.' The average increase is generally estimated at one pound of rubber for each year of the tree's life up to a certain age, which, however, I am unable to fix.

On the eastern side of Nicaragua, and especially in the Mosquito territory there are immense tracts of land suitable for the cultivation of *Castilloa elastica*. In choosing land, shelter from strong winds, the greatest enemy of young Castilloa, should be kept well in view. The seeds should be sown in a nursery bed shaded from the mid-day sun, and the young plants transferred to the hacienda when twelve months old. For each plant a hole should be dug three feet in diameter and one foot deep, and filled with fine loamy soil to which a little sand has been added. The mixture should be well-trodden down and watered night and morning for two days, when it is ready for the young Castilloa, which must be placed in its new bed at exactly the same depth as in the nursery; if it is weak, a stake support is very desirable.

Trees tapped in the wet season are estimated to yield five times as much milk as in the dry. The quantity of rubber produced therefrom depends to a great extent on the coagulating agent employed. Sixty per cent. of the milk ought to be turned into rubber. A very good agent is one ounce of alum dissolved in sixteen ounces of water. But a weak alcoholic solution will give even better results, for the process is immediate, and the solution may be used many times. In my own experiments I never lost more than forty per cent. of the bulk, and often only thirty-five per cent.

That the cultivation of *Castilloa elastica* is worth the attention of the thousands who are seeking really remunerative investments there cannot be the slightest doubt, and this the author intends to show in a work on the whole subject of india-rubber which he hopes to publish shortly. For success careful study and inquiry is imperative.—*Chambers's Journal*.

THE DISEASES OF PLANTS.

Throughout a long series of years the pages of the *Gardener's Chronicle* have from time to time conveyed much information regarding the diseases and ills connected with plant life—and its work continues, for the foes still advance. Now-a-days, however, the prevention and remedy of disease come more to the front, and naturally this aspect appeals to the cultivator of plants. There has never been any lack of suggestions for the cure of disease in our gardens and plant-houses, yet within the last ten years of thereabouts, remedies may be said to have showered on us at all times and in all kinds of gardening periodicals, till one feels lost in the numbers,

and when a pest appears amongst our plants it is difficult to know what to do.

The subject of diseases of plants is a wide one, too large to be successfully grasped, even after long experience, while in many points there is too much obscurity as to the cause of disease to allow of successful treatment of cure. From the multitude of diseases liable to appear amongst plants, two classes stand prominently forward: (1) those due to the action of parasitic plants particularly Fungi; (2) those due to injurious animals, particularly Insects. The remaining diseases have their cause in adverse soil conditions, in mistakes of cultivation, in defects in the plants themselves, or in other causes at present difficult or impossible to make out. In the present series of papers it is proposed to deal with the first class of diseases only—with those caused by the action of injurious plant-organisms on such plants as are useful to the out-door or in-door gardener. Diseases of this class are sufficiently common and disastrous enough in their results to be only too familiar, and their importance needs no further emphasising than to recall the ravages of Potato Disease, Vine Mildew, Damping-off Fungus, and the Hollyhock Rust of former days, not to mention the thousand-and-one mildews, rusts, and blights of less consequence. The subject of fungi is, to the ordinary gardener or cultivator of plants, one fraught with many difficulties arising from the minute structure and complex life-history of these tiny organisms, and any text-books available tend to bring these very difficulties into prominence. This is no doubt necessary and valuable in its way, yet we believe that, as in a "first aid" ambulance training, it is possible by a few exact observations to know enough about a fungus-pest to understand how to proceed against it. We do not then propose to deal with the fungi themselves any more than is necessary to understand them, but refer the seeker after detail in this direction to the books, some of these are—*Diseases of Field and Garden Crops*, (1884) Worthington G. Smith; *Diseases of Plants*, Professor Marshall Ward; *Diseases of Trees*, Translated from the German by Professor W. Somerville (Macmillan, 1895); *Diseases of Plants due to Cryptogamic Parasites*, Translated from the German by William G. Smith (Longmans, 1897).

For all kinds of plant-diseases the treatment is one of two kinds: (1) preventive, aimed at keeping the disease away altogether; (2) remedial, which aims at destroying the offence. To prevent disease is more truly the work of a gardener than to cure it, for, after all, his efforts towards remedy cannot go much beyond the stage of "first aid;" if more be needed, the specialist should be applied to. To keep one's plants free from disease requires more skill, foresight, and experience than to try remedies; it also demands great patience, for, as it were, the results are negative, no disease appears; but, on the other hand, the value of the crop repays all the extra care in raising, WILLIAM G. SMITH, Edinburgh.—*Gardener's Chronicle*.

LIBERIAN COFFEE.

The extension of Liberian coffee cultivation in S. India, in many cases in an experimental stage, in others on a more extensive scale, is ample excuse for my calling attention to the results actually obtained in Ceylon, and a district where there is very so far old Liberian coffee not a thousand miles from Cape Comorin.

LIBERIAN IN CEYLON.

In Ceylon in the latter seventies there was a considerable amount of land planted with what was fondly hoped was going to replace the Arabian variety. The original plants were planted at too high an elevation, and not making any satisfactory growth were removed to a lower elevation, where they thrived admirably, and I believe brought in the fortunate proprietors as much as 4 s. a cherry. What has become of all the Liberian planted in Ceylon at that time is not hard to say, as it has practically disappeared, and to such an extent that not long ago I saw Liberian coffee cultivation alluded to as a new product in a Ceylon paper. The causes of its disappearance were various, in many places the soil was unsuitable and probably the treatment, and the coffee

more or less came to an untimely end by starvation, death being in many cases accelerated by a mamoty. The low price of the coffee was another great cause; I think about 1884 it was only worth some R5 a bushel of rice coffee. This cause led to the cutting out of some decent coffee, some that I saw being so well grown that hitching an elephant on to the trees was considered a cheaper and more efficacious system of removal than by coolies. There was yet another cause, a cause that I hope Indian planters may be spared, and that was bug. Bug obtained such a hold on the coffee, and throve so well, that the only way of getting rid of the bug was cutting out the coffee. At the present day I see the Delgolle Company refer to Librician coffee, of which they have a considerable acreage of young coffee, in a most discouraging way, both as regards present crop and future prospects. As the result of all the Ceylon experience, it may safely be inferred that Liberian coffee wants good soil. Crossing the water there is some old Liberian to be found which bore well and steadily for years, but is now unfortunately in a very unhealthy state.

LIBERIAN IN INDIA.

One clearing along a stream being, I believe, affected by the extensive felling of the forest on both sides which must have had a great effect on the moisture during the dry seasons, and another clearing, which was under heavy forest shade, has been terribly damaged by thinning the shade so much so that it is being densely planted up with artificial shade in the hope it may save it. There would be nothing very serious in this as it would only point to shade being a desideratum for Liberian, but the most serious thing is the failure of young coffee planted three to four years ago, even when planted with shade. This would, I think, point to deterioration of the seed, and I am confirmed in this by the opinion of the planter who originally planted the old coffee, who holds that Liberian does not grow as it used to. There is no doubt that looking at any lately planted coffee and comparing it with the old original trees, that it seems an impossibility for the stems to attain the same size within any reasonable time. There is another item of interest in regard to Liberian, and that is that the crop has been a complete failure last year and the year before through drought, the blossom failing to set. That long droughts are not good for it I think may be taken as proved by the success of this species in the Straits, where I believe they seldom have a month of the year without rain.

DIFFERENT JATS OF COFFEE.

There is a very important thing to be borne in mind in planting Liberian, and that is that there are distinct varieties of the coffee, one bearing much heavier than the other. So that in starting a Liberian as in a tea clearing, the importance of jat is of vital importance. From all I have seen of Liberian in Ceylon and on the continent, the successful growth of the tree seems to require—

- I. Good soil.
- II. Plenty of moisture.
- III. Shade where at all liable to drought.
- IV. Selection of the right jat.

In reference to the deterioration of the trees, it is harder to know how to meet that. Importation of fresh seed from Liberia would undoubtedly be the best way, provided any guarantee could be had that it was the right variety and carefully selected, but it is questionable I think whether it would not be better to rely on the survival of the fittest; careful selection and cultivation of the parent seed trees would I believe be as good a way as any to ensure success of future clearings and avoid repeating past mistakes. I may be wrong, but I am strongly of opinion that sufficient care has not in many cases been paid to the selection of the seed. Taking a bushel of parchment out the store for seed is hardly the way to command success. I hope some of your readers will let us know how far their experience of Liberian coffee agrees or differs from the somewhat unsatisfactory experiences I have related.—B. NELSON.—*Planting Opinion*.

FRUIT CULTURE IN CEYLON— ORANGES.

One direction in which we are rather anxious that the enthusiasm of the new Director of our Botanic Gardens should benefit the agriculturist, is in connection with Fruit Culture. We have seen, and heard of, many interesting experiments with the cultivation of fruit, not alone in private gardens, but also on estates supervised by planters of horticultural tastes, whose leisure hours are not too exclusively devoted to "sports and pastimes." Few pursuits can give greater pleasure than horticulture; while scarcely anything can contribute so largely to the pleasures of the table and the maintenance of health in a tropical climate, as the produce of the garden—flowers, fruits and vegetables. The Udapussellawa, Maturata, New Galway and Nuwara Eliya planters have always been foremost in their interest in the cultivation of fruit; and of recent years Mr. Nock's operations at Hakgala have contributed materially to maintain and stimulate that interest, and to add to the list of table delicacies. But there is no reason why Fruit Culture should be confined to the upland districts, and we know some lowcountry planters—prominent among them the veteran Mr. W. H. Wright of Mirigama—who have in the Western Province, taken an intelligent and successful interest in the growth and propagation of indigenous and exotic fruits. Generally, almost exclusively, the efforts of the growers have been directed towards supplying their own personal needs, and, perhaps, those of their own friends; and seldom have attempts in the past, been made to supply the Colombo market or shipping. We are bound to say that such as have grown fruit beyond their personal requirements, and made the attempts to find a market, have not a very encouraging story to tell. "Fruit Culture looks very well, indeed, on paper," they say; "and if one could only derive from 50, or even 20 acres, the profits estimated per acre from limes, or oranges or pineapples, one would not need to trouble oneself at all about tea, or coconuts, or other big products. It is when the fruits have to go to market that one realizes the hopelessness of the venture, with railway freight exorbitant and the market rates infinitesimal." We cannot dispute the facts which our friends submit for consideration; but we refuse to accept the conclusions as inevitable, or permanent. There are difficulties in the way of every new venture; and until supply and demand are fairly regulated by experience, the grower must be prepared for some disappointment. We have known a Kentish fruit grower send 50 bushels of plums to Covent Garden and get back a debit note for 1s 6d! A rush of plums spoilt the market for the time, and railway rates—since amended—were too high. So in Ceylon we want special "fruit" rates by railway and market experiments, before giving up hope in this new industry. For how many years, for instance, was not tea, now the first among our great exports, looked upon as an interesting shrub, but without any commercial value in the special circumstances of the island? We have heard a story of the Messrs. Worms who exhibited some specimens of made tea, manufactured on one of their Ramboda or Pussellawa properties by an imported Chinaman, at a Colombo Agri-Horticultural Show. Mr. George Wall, himself the largest local importer of China tea—coffee being then King here—was one of the Judges

at the Show and pronounced the samples excellent, and worth a guinea a lb. "It cost us about five guineas a lb. to make," said the shrewd and enterprising elder Jewish Planter-Merchant Mr. Gabriel Worms! And yet, the collapse of coffee was the opportunity for tea, which is now manufactured and placed in the market at a ridiculously low cost from certain favoured places. The laws of supply and demand have solved problems which once seemed insoluble; while improvements in machinery, co-operation, and the handling of increasing quantities, have helped to reduce the cost of production to a minimum. So it must be—and we trust soon will be—with Fruit Culture in Ceylon. There is money even in the commoner fruits of the country, such as those we have named; but the grower will, for some time, have to be his own purveyor until a regular trade is established. One obstacle to success, which has been brought to our notice by a lowcountry planter who grew Mauritius pines in abundance a few years since, is the contract system which finds favour with Hotel Managers, and specially with Steamer Agents. Applications to such quarters, too often result in references to the Dubashes and Purveyors from whom alone they draw all supplies; and these are, of course, only prepared to pay bazaar wholesale prices of the lowest standard! Quality, size and flavour were denied a place, in the calculation. The dozen was their standard! And being paid by the dozen, they supplied by the dozen without troubling themselves in the least about quality! What wonder that, under such circumstances, Ceylon fruit served up on board-ship are generally a disgrace to the island, and that passengers who drop in for a day or two into our hotels, carry away a very poor notion of local fruit of all kinds. Surely, it ought to be worth some one's while to start a really good fruit-stall in the Fort, or within easy reach of it, where the best specimens of local fruit could be made available to householders and passengers. The drawback of the climate can now be guarded against through the cheapness of ice, while a steady demand might result even in the growing of some at least of our fruits out of season. Perhaps the enterprising promoters of the Cold Storage Company will see in our suggestion a means of increasing the usefulness of their charge and supplying a farther want of the community. We are aware that Mr. Wright, already mentioned, has had an interesting and successful experience in one direction this very season. For the present we do not go into particulars; but ere long we may have some account of his fruit-growing experiments from this veteran planter.

So much for the commercial aspects of the question, which we have thought it necessary to discuss fully, quite as much in the hope of eliciting useful suggestions, as of making the public fairly acquainted with the difficulties in the way of fruit-growing as an investment and a source of income. We now turn to the cultural aspect of one of our commonest and most wholesome fruits, which has been suggested by an article in the *Trinidad Bulletin* published by the Botanical Department of that island. The article is a most suggestive one, from the pen of Mr. Hart, the Superintendent of the Royal Botanic Gardens, and emphasizes the need of grafting in dealing with the citrus species. To the question, do oranges come true from seed? the writer, after a careful consideration of the *pros* and *cons*, returns an answer

in the negative. Though direct evidence may be wanting, tracing plants from the seed in the nursery to their growth duly labelled, until they fruit, the experience of observant people corresponds with the general belief among, what may be called, the uneducated classes, that sweet orange seeds do not invariably produce sweet orange plants. The testimony of Professor McOwan, in his Manual of Practical Orchard Work for Cape Colony, is quoted in the following terms:—

"It would therefore appear that the colony possessed in the first instance excellent named sorts of this delicious fruit, but by the cultural error of propagating by seeds a mongrel race has sprung up, which does justice neither to the exceptionally suitable climate of the Cape nor to the possibilities of the fruit itself."

And the Professor thus quotes an eminent Florida grower:—

"Do not let any man or number of men in a pomological convention induce you to establish a seedling orange grove. If you do, you will some of these fine days wake up from a Rip-Van-Winkle dream and find yourself as far behind the age as he is represented to have been.

"No two seedling orange trees will ever produce fruit exactly alike, consequently your fruit will become promiscuous and variable in character and quality, and your neighbours who have selected known and uniform varieties will find a more ready demand and sale at fully 50 per cent advance on what you can get for your mixed promiscuous fruit."

Another authority, while admitting that "seedlings of the sweet orange produce fruit similar to those produced by the parent," observes that "there is yet much variation in the fruit from such seedlings." Now, these are important facts to remember by those who would engage in orange culture—that a sweet orange seed may produce a tree bearing sour or bitter fruit, and that if the tree be true to type as regards sweetness, the quality of the fruit may be very different from that of the parent tree. In regard to the production of the "bitter sweet orange," we have curious confirmation from a Veyangoda planter, who has a grove of sweet and sour oranges planted by the former proprietor as sweet, and whose own plantation of sweet from seed has produced different varieties. Last year one of these plants had a first crop of a few fruits which he took for large rough skinned oranges. They ripened yellow and looked very tempting; but when cut the rind was almost as thick as that of the shaddock, without the spongy protuberance at the stem; while the taste was different from both the orange and the shaddock. He finds no difficulty in calling it now a bitter sweet! The remedy for this variation from type is said to be grafting; and here is what Mr. Hart writes:—

"We can say without hesitation grafted plants for choice, if planters can afford it; for though costing more, it is true economy in the long run. Such plants will fruit earlier, will be true to name, will deceive no one, will allow the grower to put a regular class of fruit upon the market; their quality can be depended upon, and a fruit can be grown exactly to suit the grower's taste, or to suit any particular demand. Grafted plants will certainly be much dearer to plant than seedlings, and at present few would invest at the rates which would be charged for them; but if a certain and continuous demand arose, this price would certainly be reduced and grafted trees would be sold at reasonable rates." This is one direction in which the Royal Botanic Gardens and the School of Agriculture should combine their forces for the public good, by raising grafts, giving "demonstrations" of the best methods of grafting, and teaching practical

grafting as a special subject. The article itself is so interesting, and likely to prove so useful, that we shall reproduce it in full in the *Tropical Agriculturist*. As we have said, the orange is one of our commonest fruits and it is grown in almost every native garden; but—as usual in the case of Sinhalese—without any attention to cultivation. We have tasted oranges of splendid flavour, equal to anything we have tried on the Continent of Europe or in England; but the flavour can be ascertained only after tasting the fruit! The general belief is that oranges grown on the seaboard, or in the low-country, are far superior to those grown upcountry. If the verdict be correct, what is the explanation? Meanwhile, we trust that what we have written may stimulate investigation and experiments.

BOTANICAL INVESTIGATIONS.

The news comes from Cambridge that the special Board for Biology and Geology has voted £100 to Mr. H. H. W. Pearson, B.A., of Christ's College in aid of his expenses in visiting Ceylon for the purpose of making Botanical Investigations, the grant being conditional on the recipient reporting to the Vice Chancellor the results of investigations in a form suitable for publication. The grant is made from the "Wort's Travelling Scholars' Fund." A grant of £300 is also made to Dr. Haddon for anthropological researches in Torres Straits. As Mr. Pearson comes from the same College as Mr. Willis of Peradeniya, they will no doubt co-operate heartily in the work to be undertaken.—*London Cor.*, local "Independent." [Dr. Haddon is Professor Alfred C. Haddon also of Christ College who spent a year in Torres Straits and New Guinea some time ago. Professor Haddon is an enthusiastic Naturalist and Anthropologist.—*Ed. T.A.*]

PLANTING IN JAVA.

(From a Correspondent.)

I have a letter from Java in which I get the following information:—Java soil is a long way ahead of Ceylon, but for all that they have many difficulties to overcome. Labour is scarce, and very bad at its best. Cholera is very bad in Soorabaya. Sugar planting is almost at a standstill owing to heavy fall in prices. They expect a very heavy crop.

A TRIP TO THE TRAVANCORE HILLS.

FINLAY MUIR'S ESTATES, &c.

(From a Correspondent.)

From Bodynaikanur up to Devikulam is a ride of about 30 miles, 5 to the foot of the hills, 10 up a terribly steep ghaut some 4,500 ft. in height, and then 15 more through a beautiful grass valley shut in by high cliffs and fringed with thick forest, rising at the end up to nearly 6,000 ft. Once over this pass we enter the property of the North Travancore Agricultural Society, which, with the exception of a few private estates, is now owned by Finlay Muir & Co., whose operations are spread over Ceylon, Assam and Travancore, and who have a capital of two millions sterling to back them up. About 2½ years ago Sir John Muir bought up the whole of the shares of the old Society. The shareholders did not benefit much, for they only got about R70 for every R100 invested some 15 years previously. But

sic vos non vobis appears to be the motto of all pioneer Companies, and Sir John Muir acquired an estate of some hundred square miles with at least thirty thousand acres of virgin forest for next to nothing. Counting only the forest land, the cost was not more than R10 per acre for land which in Ceylon is worth from R150 to R200. Since the purchase, the new Company has not let the grass grow under its feet. Something like 5,000 acres have now been cleared and are being planted out with tea and coffee. The original Company confined its operations almost exclusively to cinchona, but the slump in the price of bark left so small a margin of profit that most of the trees have been cut down and replaced by tea or coffee. There are, however, still some 700 acres of cinchona belonging principally to private individuals, and the bark yields a very good percentage. The headquarters of the new Company are at Munaar, about 8 miles west of Devikulam, in a beautiful valley where three rivers meet, to fall shortly afterwards, through a gap in the hills, nearly 1,000 ft. into the Travancore low country. Here the visitor cannot fail to be struck by the enormous energy that has been displayed. On all sides are huge clearings divided into estates of about 500 acres each, looked after by a manager and two *Chinna Dorais*. The elevation here is about 4,500 ft. and the lower part of the hills are therefore planted with coffee, the higher ranges being reserved for tea.

From Munaar to the Pulliar Valley is a ride of 14 miles, first of all through a pretty valley with what ought to be a trout stream running at the bottom, past two big tea clearings and through another, and so up to the top of the Pulliar gap. Here we look almost due North, down a valley sloping from about 5,000 ft. down to the Anjanaad and the low country of Coimbatore, distant between 60 and 70 miles. To the right are steep, rocky mountains, with precipices falling sheer 1,000 ft. and more, and above them towers the summit of Anaimoody the highest peak of Southern India, being about 50 feet higher than Dodabetta. These hills are generally covered with thick mist and are still the haunt of the ibex, whilst the valley at the head of which we stand used to be the favourite feeding ground of herds of elephants. For four or five miles we go down through thick virgin forest with a dense undergrowth. As we get down into the valley we come across extensive coffee clearings. These belong entirely to private individuals. Some of these, however, have recently been bought out by the new Company. Some of the coffee here is very fine, and one small estate of 60 acres, which was only planted out 2½ years ago, was pointed out to me as having been recently valued by a Ceylon expert at £6,500, or more than £100 per acre. The soil is excellent, for the dense forest has until now never been touched and the ground is thick with the vegetable accumulations of centuries. But the great drawback of these valleys seems to be the violence of the monsoon. From the middle of June until the end of August the rain comes down in perfect torrents accompanied by a heavy wind. I was told that last year in Munaar the rainfall was over 200 inches, and here in Pulliar it was over 180. The consequence is that not only are the planters cut off from their communications, but they are also put to considerable trouble and expense in protecting the young plants and trees from the wind and rain. For three consecutive years after the coffee seedling has

been planted, it has to be staked, which involves a considerable amount of labour and cost. Even then the wind and rain cause many vacancies, which have to be replaced, not to speak of occasional landslips which may carry away an acre or two of promising trees. The valley we are now in is affected by both monsoons and the N.E. wind has a very withering effect on the young trees especially, and it is chiefly where there is a South aspect that the plantations look better. But this is a very valuable valley and has produced some very fine crops. In course of time no doubt the new Company will buy up the old estates and open out the remaining forest.

From Pulliar back to Devikulam by another route is about 15 miles. After climbing a high hill we pass through an extensive cinchona clearing of nearly 500 acres, lately the property of a small Company in Madras, but recently bought by Finlay, Muir & Co. Uncommonly fine trees they are too, but until there is a rise in the price of the unit they are hardly likely to be barked. We then go down a steep hill, cross one of the Munaar tributaries, up through a thick forest with a dense undergrowth of creepers and ferns, and then over some grass hills, past a 300 acre cinchona clearing belonging to Mr. Kindersley, of Ootacamund, through some other cinchona clearings belonging to the Devikulam Company, one of the two private Companies left, and so back to Devikulam, after having completed a round about 45 miles in circumference.

We have, however, only seen about one half of the whole concession. To the West the thick forest extends down to 1000 ft. from the low country, and work is actively going on there, whilst to the East there are also large clearings where tea is being planted out. Although Finlay, Muir and Co. own about 30,000 acres of forest in this concession alone, this extensive tract of unopened land does not seem to satisfy them, for they have also purchased from the Travancore Government other forest land outside the concession and towards the British boundary. Here they are engaged on a large clearing for coffee, about 500 acres in extent for which they have not hesitated to pay as much as R50 and R60 per acre, although the concession forest stands them in at R10 per acre only—leaving the enormous extent of grass land entirely out of the question. As was to be expected, this activity has excited a considerable amount of competition, and Mr. Knight, the well known planter of Ceylon and Peernaad, has recently acquired 1,000 acres in a valley outside the concession, for a large portion of which he had to pay as much as £5 per acre. Within the concession itself land is no longer procurable, for Finlay, Muir and Co. will not part with an acre, and there seems little doubt that in a very short time all the available forest land will be sold at prices ranging above £10. It seems a pity that all this valuable land should be lost to Madras enterprise. The original North Travancore Company, which obtained the concession, languished for 15 years. It had too little capital of its own to open out more than a fraction of the huge concession; very few private planters took up land even at the low rate of R15 or R20 per acre, and the original shareholders had to sell out at a loss of 30 per cent besides interest for 15 years. Now it turns out to be a valuable property, and a concession the value of which may be said to be nearly R30 lakhs has passed into other hands

for less than three! One natural effect of this great activity has been to send up the price of labour. Cooly labour now costs 5 annas per diem, and many of the managers are bitterly complaining about the contractors and the difficulty of recovering advances. A curious and significant incident in connection with famine labour may be mentioned here. Sir John Muir offered to employ a gang of 500 Cuddapah famine coolies. Scarcely had they arrived at Munaar than in spite of good wages and a cool climate a great part of them absconded. Government work on famine dole in a parched-up country was pleasanter to them than hard work in a strange country at double the wages. The incident is significant of the apathy of the Indian cooly, who prefers dying at home to working in a distant district.

It may be safely calculated that in two or three years' time there will be about 25,000 acres of forest planted out on these hills, yielding a produce of not less than 5,000 tons annually, exclusive of traffic in rice, and other supplies. A very large portion of this must find its way to the Cumbum Valley for transport to Tuticorin, the nearest harbour, and would go a long way towards providing a dividend for the electric railway which ought to be constructed there. At present there is no agency on the hills, and not even a shop. All money for payment to coolies, stores, rice, supplies, &c., are sent from Madras, the money either in specie or in notes at considerable inconvenience and loss of time. Here again would seem to be an opportunity which Madras firms would do well not to lose.—*M. Mail*, June 30.

TEA IN COORG.

Sir,—In your issue of the 25th June, in the course of some editorial remarks on the proceedings of the Annual General Meeting of the Coorg Planters' Association, you state:—"Thus one more coffee district has succumbed to favourable prospects held out by tea, and very soon we may expect to see Coorg in the transition stage from coffee to tea in which Wynaad and the Nilgiris and some other districts now are." Kindly allow me to suggest that the sentence as it stands would lead one to infer that the cultivation of tea is rapidly displacing that of coffee in South India—whereas, if you will kindly refer to the latest statistics of the Planting Industry collected by *Planting Opinion*, or by the U. P. A. S. I., you will see that king coffee not only reigns supreme, but seems bent on maintaining his supremacy, to judge from the large extensions made, and the new districts that are being conquered, since the nineties began. Only Travancore figures as far more a tea than a coffee district; but this has been its condition for years past, I believe. The tea planted in the districts of the Nilgiris, Mysore, Wynaad, Coorg, Pulnies, &c. is either *nil*, or very small in extent, except on the Nilgiris. On the Nilgiris there has always been, concurrently with coffee, a fair area of tea cultivated. The same in Wynaad, but to a very small extent only, until recently, when lands, years ago proved unsuitable for coffee, are now being to some extent reclaimed by tea; but to say that Wynaad and the Nilgiris are in the transition stage from coffee to tea is altogether contrary to facts, as it implies that the cultivation of coffee is being given up for that of tea. The cultivation of tea is extending, it is true, but it by no means follows that it is going to, or, for that matter, is intended, to displace coffee. On some very old coffee land, or on land more or less originally unsuited for coffee, it may do so, and thereby prove a valuable adjunct to coffee. Nor can I see that the way tea is mentioned in the Report of the proceed-

ings of the Coorg Planters' Association warrants the inference that Coorg expects to be in a transition stage from coffee to tea. I am sure, most planters will have read your remarks with much surprise. We have had two most erratic, and quite uncommon, flowering seasons, first, in the unprecedented drought of the spring of 1896—a good deal worse than the prolonged drought of 1895,—followed by a want of seasonable cold weather in 1896-1897 after quite abnormal rains in the fall of 1896 and early rains this spring so soon as February last; but I have yet to meet the man who, in the face of the vigour and health of the coffee tree of today, and of its most rapid recovery from an attack of leaf disease a few months back, the like of which I do not think the districts have been visited with since 1891, and who has an estate worth anything, is prepared calmly to sit down, and begin to count up the cost of converting his property into tea on the ground that his coffee is not going to bear any more. I have heard of one man who did this, some years ago, and then within 18 months picked out of the best crops his place ever gave, and it is still going strong! —*M. Mail*, July 1. SEMPER FLOREAT.

THE SOLOMON ISLANDS.

Mr. Woodford, in the course of his sojourns, found some difficulty in getting at terms with the natives owing to the number of dialects. Fijian, however, appears to be very similar in roots and inflections, and in this language the Commissioner could generally make himself intelligible. The natives themselves live on very easy fare. One of their principal foods is a preparation of sago flour and pounded almonds. This they bake into cakes. "These cakes," Mr. Woodford testifies, "are most excellent and sustaining food. From their portability they are taken by the natives upon canoe voyages, as they are not liable to damage by salt water and, moreover, are most convenient to sit upon." Many more interesting things does Mr. Woodford tell about the Protectorate and the people. The trade, which is done entirely by Sydney merchants, is mainly in copra (dried half-coconuts from which oil is extracted), ivory nuts (the fruit of the sago palm used chiefly for making buttons), and pearl and turtle shells. Mr. Woodford, who has visited the islands before has great belief in the possibilities of a larger trade in the future, and considers that capital might be profitably expended in the growing and gathering of indiarubber, sago, sponges, and certain timbers. The European population, though it numbers only fifty souls, is growing with the prospects of increased trade. In the Solomons, as in other island groups of the Pacific Oceania, the British Protectorate does not cover the whole Archipelago. The northern islands are in the German sphere of influence. But the Teutons have imposed such taxation, in the way of licence fees and export duties, that the traders in the British Protectorate have practically given up visiting the islands north of the line of demarcation.—*Scotsman*, June 10.

CACAO DISEASE.

MR. E. E. GREEN, who is naturally much interested in this matter, writes in answer to our enquiry:—

"As for the 'poochie' theory, neither my own observations nor any arguments brought forward by any correspondents, at all tend to shake my belief in the independent nature of the disease. But I keep myself quite open to fresh evidence and hope that personal examination in the various affected districts will settle the matter one way or the other. Mr. Van Der Poorten's argument in favour of the 'poochie' theory, is merely that 'the dead wood is full of beetles, and that they are often attracted in the large quantities by light.' This is extremely probable; but is as easily explicable by the fact that these boring beetles are always at-

tracted by dead and diseased wood, and if canker had been present on the estate for some time there would naturally be a large increase in the number of the insects which would have been freely breeding in the decaying wood bark."

Seeing that two or three kinds of "poochies" are recognised enemies of cacao in Trinidad and elsewhere, it would seem not unlikely that Ceylon should be troubled with one or other in addition to "canker." But the attack on each estate should be the subject of careful inspection by the Entomologist.

COFFEE IN FIJI.

WE append a specimen of the glowing, but defective if not unreliable, paragraphs which find their way into the columns of inexperienced journalists in discussing products which they would fain see established and extended in their midst. We take the following from the latest *Fiji Times* :—

"A very handsome sample of Arabica coffee in parchment is on view at this office from the small estate of Mr. R. Morel, and has been much admired by connoisseurs, and pronounced by them equal to coffee grown in any part of the world. The grower says that his crop is a very prolific one this year, and will yield more than fifteen cwt. to the acre. This is a very exceptional yield, as five cwt. is considered a good average crop, although in some favoured places in Ceylon we have read of 8 to 10 cwt., but this was exceptional and not the rule. Mr. Morel's plantation is situated on an exposed portion of the coast, and is quite free of any disease."

In the first place, no mention is made of the area of "the small estate." To secure a crop of 15 cwt. from one acre or even up to 10 acres once in a way, would be no great feat if high or rich garden cultivation were resorted to; but that would, obviously be no criterion of what 100 acres treated in the ordinary way would yield. But we doubt Mr. Morel's estimate; and we are borne out by the opinion of a planter who knows Fiji well :—

"No reliance can be placed on the estimates made by the settlers there as they have never properly grown and cultivated coffee. The only two men I know in Fiji who could at present give a fair estimate of crop on trees are Dixon, who used to be on Kelvin, Dolobage, in the old coffee days, and Geo. Drummond (an older planter than Dixon) and a brother of Gangwarily Drummond. These two know all about coffee and could give reliable estimates. The others only go by guess-work. I have often seen fields put down as bearing 12, 15, and even 20 cwt. an acre when at the outside they only had 5 to 6 on the trees and when laughed at have offered to back my opinion and invariably won. The same applies to leaf disease. Settlers will tell you there's not a trace of it on their trees, and on examination one who knows anything of *Hemiteia vastatrix* can see it distinctly. Leaf disease is all over Fiji: this with dear and scarce labour, not to mention hurricanes, will militate against successful coffee-growing there."

COCONUT LAND IN THE SOUTHERN PROVINCE. —Mr. Wace in his Report for 1896 states that there is still a large extent of suitable land available for coconuts in his province. It ought to be surveyed and put up for auction sale in convenient blocks as soon as possible.

COFFEE PLANTING ON THE SHEVAROY HILLS.

(From a Correspondent.)

The Shevaroy Hills, which I visited early in June, after an absence of 30 years, gave me the impression of having been asleep for those 30 years. Nothing seems to have altered. There is the same steep ghaat, impossible for wheeled traffic, there are the same old bungalows with some additions—there is the same diminutive lake which always looks half empty: there is a tiny Reading Room, which has not as yet developed into a Club, and there is a general air of drowsiness over the place. But Yercaud is exceedingly pretty notwithstanding. The air is cool and pleasant, a nice wind is blowing, and the hollow lanes fringed by flowering hedges remind one of the old country. In one respect some progress has been made, and that is in the extension of coffee cultivation. Almost all the land that has not been reserved by the Government has been taken up and planted out. Already half way up, at an elevation of about 2,000 ft.,

THE PLANTATIONS COMMENCE.

and improve the higher we rise. Once on the top of the hills, almost every compound is full of coffee bushes, and any one wishing to open out a new plantation must go a distance of 14 or 15 miles. At the time of my visit the coffee berries were all set after the second or April blossom. In a great many of the clearings the trees were perfectly loaded with crop, and on the whole I have seldom seen a finer show. Many points struck me as very different to the system of cultivation I had seen elsewhere, especially in Travancore, whence I had just come. In the first place, there seems to be very little virgin forest. There is a small piece still standing near the lake, known as the Sacred Grove, which shows what the virgin forest really was. The rest of the forest seemed to consist almost entirely of secondary growth, sprung up during the last 60 or 70 years. None of these trees are very large. What struck me first of all was the large amount of natural shade. From a distance, a hill side will have all the appearance of forest, but as you come closer you find that it is a plantation. Only some of the trees have been felled and the remainder left for shade. In Travancore they make a clean sweep of the whole of the trees, burn them and then plant out artificial shade trees. The next thing that seemed to me strange was

THE HEIGHT OF THE COFFEE BUSHES.

Instead of being topped at 3 ft. from the ground, most of them were about 6 ft. and some as high as 10 ft. In some places the trees had been coppiced and fresh shoots were springing up from the stools and bearing a good crop. One result of this system of growth seems to be that there is not such a show of leaf. In plantations where the trees are lopped 3 ft. from the ground, the branches spread out so as to cover the whole soil, of which in a well planted tote there should be as little to be seen as possible. Another thing that struck me as peculiar was the absence—with few exceptions—of estate roads and paths, which should make supervision difficult.

During my stay I visited several estates and made many enquiries from different persons. One great

ADVANTAGE OF THE SHEVAROYS

seems to be the mildness of the monsoon. There are no violent bursts as there are in Travancore. There is but little wind, indeed so little that the young plants are never staked, and it is owing to this absence of wind that there is no danger in allowing the coffee trees to grow higher than elsewhere. Instead of heavy torrents of rain lasting for several days together, they only get good showers every day, with breaks of several hours during the monsoon months and a fairly steady supply during the rest of the year. This has been a dry year, March and part of April especially so, but in May they had 9 inches

of rain, and when I was there, early in June, everything was looking fresh and green. The soil for the most part seems to be excellent, and owing to the number of cattle on the hills, and the nearness of the plains, manure is easily available, and the proximity of the railway makes the supply of fish and artificial manures less expensive than on the Travancore Hills. Manure is therefore extensively used and apparently with excellent results, for the average yield appears to be 5 cwt. an acre, and some of the estates which are 25 to 30 years' old show no signs of being exhausted. Leaf disease appears to be unknown or at all events in only a very mild form, and the grub gives no trouble.

FIVE CWT. AN ACRE

is a very good out-turn and at present prices should give a return of nearly R350 per acre, for Shevaroy coffee has a very good name in the market and realises good prices. But most of the estates are very small, and it therefore stands to reason that when the proprietor has to make a living out of it and maintain a house and family, there is not much left for the estate. A great many of these estates have also been opened out on borrowed money, and 10 to 15 per cent. interest accruing on a growing estate is calculated to saddle it, when it comes into full bearing, with a load of debt which it may take years to remove, and most likely ruin the proprietor in the end. It seems doubtful whether a system of small proprietors is calculated to properly develop a coffee country, because the cost of supervision falls with undue weight on a small estate. Supervision is generally calculated at the rate of Re. 1 per acre, and when this charge is distributed over an estate of from 300 to 500 acres it does not become an undue burden, but if the estate is only 50 or 60 acres in size this rate is not sufficient for the maintenance of the Superintendent. Whatever, therefore, is paid to him in excess is so much taken from what ought to be spent on the estate itself. This, therefore, would seem to account for the fact that with a favourable climate, excellent soil, cheap labour (3 as. per diem) and the vicinity of a railway, Shevaroy planters as a rule are not so prosperous as one would expect them to be. Here again the Government seems to have done very little towards helping the enterprise. Only now, after more than half a century of planting industry, has it been decided

TO BUILD A CART ROAD.

and until that is made everything has to be carried up the ghaat by coolies. The only representative of the law on the hills is a Native Deputy Tahsildar, and there is no Bank or Government Treasury from which the planters can draw money to pay their workmen, &c. In this respect the Travancore Government has been more liberal and has appointed a European magistrate to exercise jurisdiction over the European planters of the High Range.

At the time of our visit

YERCAUD

was very full and rooms were not obtainable for love or money, unless ordered long before. It seems strange that with this annual influx of visitors so little is done to provide them with amusement. A couple of tennis courts and a diminutive reading room are scarcely sufficient. In Yercaud itself there are few unoccupied building sites available and where one can be found it fetches from Rs50 to Rs1,000 per acre. The great want seems to be water. There are but few streams which last throughout the year, in striking contrast to the Travancore Hills, where almost every valley has its little river. The stream which feeds the lake and flows down to the West, and another small river, the Vanniar, which rises near the Green Hills and flows to the South, appear to be the only perennial streams near Yercaud. This is a want which it is difficult to supply, for it is not easy to sink a well on a hill range. But every place must have its drawbacks and on the whole the advantages of Yercaud far outweigh its disadvantages. The scenery is charming, and the range of hills being comparatively small in extent, almost

every hill top has a view over a wooded valley, with a glimpse of the low country beyond, dotted with gleaming tanks and patches of green cultivation. Its accessibility is also a great advantage, whilst the change of climate is not so abrupt as is that of Ootacamund. The hills certainly deserve more attention from the inhabitants of Madras and the expenditure of more capital in developing their resources. —*M. Mail*, July 1.

A TIN AND COFFEE COUNTRY.

THE CONFEDERATED STATES OF MALAYA.

[In these articles the writer chiefly describes Perak, one of the Malayan States, with its races of Malays, Chinese, and Sakais, or aborigines. The island produces five-eighths of the tin consumption of the world, and promises to be a fine coffee producing country.]

Hitherto the industries of Perak might have been described by the one word

"TIN."

This is no longer the case. The extensions of the railway and the improvement of communications, coupled with other causes, such as the depreciation in the value of tin, and appreciation of coconuts, coffee, and other tropical products, has brought agriculture and the development of the waste forest land very much into the foreground. There has been special progress in 1896, when the wealthy Chinaman, equally with the European, and often conjointly with him, began to invest in land, and once John has begun there is no telling when he may stop if tin does not rise above what is now considered rather a low price. The State at last has come to realise that, while it was consuming its capital in tin at a tremendous rate, it was doing but little to develop its very extensive forest land, exceedingly well suited for the growth of all tropical products.

COCONUT AND SUGAR PLANTATIONS

have been for many years carried on successfully in Province Wellesley, opposite Penang, and other parts of the Straits; and during the last few years the planting of coffee (Liberian) has advanced sufficiently to show that the soil and climate will produce this variety of coffee abundantly and of good quality. In Selangor there are already many estates established and producing, but in Perak coffee planting on any large scale was not gone into until within the last year or two, with the exception of two or three estates, each in separate districts. One of these, having a planted area of 250 acres in bearing, between six and seven years old, gave in 1895 a return of 6½ cwt. of clean coffee for the market, and the extensions of a year or two old on some estate promise to do still better. These are the results in Perak. Other States have done as well, and the return is what may be ordinarily looked for. The leaf disease which destroyed the Arabian coffee in Ceylon is certainly present in Perak; but in the case of the stronger and more vigorous

LIBERIAN TREE

it has not hitherto done any damage worth speaking of, and it is the general opinion that with this variety of coffee the disease is powerless to do much harm, and may be discounted. Judging by the experience already acquired, and the results attained, I see no reason why the Malay States should not become extensive growers of the Liberian coffee tree, and make up for the million cwts. lost to British Colonial produce when the leaf disease wiped almost out of existence the Arabian variety in Ceylon.

Not a few of your readers have been, if they are not now, interested in coffee, directly or indirectly, and those may be curious to know how things are done in connection with coffee planting in Perak, where conditions are different from those that prevailed in Ceylon in the old palmy days. In the first place, the Government gives the land on

PERPETUAL LEASE

at an annual rental of half-a-dollar (little more than one shilling) per acre, and for every acre cleared and planted it allows a forest reserve of two acres

free of rent till it is required. There is besides an export duty on coffee of 2½ per cent ad valorem, that is, all the rent and taxes to pay. All imports, except wines and spirits, are free of duty. In fact the ports of Perak are practically free. The polite Malays do all the felling and clearing. It is gentlemanly work that can be done in their own way, and in the doing of which they can take their rest at will, and smoke their cigarettes as often as they like. Such freedom suits their lazy, lounging habits, and easy-going, sufficient-for-the-day disposition.

The more muscular and uncouth

CHINAMAN

follows. He cuts the roads and drains, and digs big holes for the coconut, and smaller holes for the coffee. The two products are sometimes interplanted, the one slow-growing, coming into full bearing in ten years; and the other quicker, giving crop in the third year, and being in full bearing in the fifth or sixth. The light work of making and tending nurseries, taking the plants therefrom, filling the holes with good soil, and putting the plants therein, is, as a rule, done by the slim Indian Tamils, though the Malays are gradually getting into this work, and do a fair day's work when they can gather sufficient energy to compete with the Tamil, whom they despise.

THE WORK OF UPKEEP

of the estate is in Perak rather more expensive than in Ceylon, not so much from difference in cost of labour (which is as sixpence in the latter to ninepence in the former) as from the more rapid growth of weeds in a more forcing and at the same time more equable climate, much the same all the year round, with a mean temperature of 80 degrees, and a well-distributed rainfall averaging 120 inches per annum. There is never a day without sunshine, there is hardly ever a month without rain, though it does come down "a plumper" in some months more than in others, causing havoc to roads and to drains, of which many are required to meet these downpours, and so save damage by wash. The invariable sunshine, even distribution of rainfall, and absence of high winds are valuable elements in producing, ripening, and curing crop.

The disturbance of the soil to any extent in tropical lands gives out malarial gases, and fever results. For this the planter has to be prepared, and where there is a large charge he is often kept busy with his medicine chest, for there is no doctor or hospital within many miles, and fever treated quickly is as a rule fever treated successfully. The methods may be wrong and the doses strong, but the cooly has faith in his master and lives.

Both coconut and coffee plants have in their youth enemies. The hoar from the forest brings a following into the plantation. His tribe have a sweet tooth for the young coconut, but are too wily to be trapped, so night has to be made hideous by tum-tumming to make believe that high festival is being kept, and Mr. Piggy had better come another time. Then there come the pests to worry—beetles that have to be caught, and "bug" that has to be sketched. But in spite of all these and more, the coconut and coffee grow luxuriantly in the favoured clime of Perak. So much for the agricultural industry.—*Inverness Courier*, June 18. D.M.

THE DUMBULA VALLEY TEA COMPANY.—It is no wonder the shares of this Company have sprung up, after the glowing account of its position and prospects given in the "Limited Liability Review." There can be no doubt the Directors have behaved well by the shareholders in paying them quarterly dividends and if they can complete the 10 per cent and show earnings equal to 15 for their first year,—they will deserve all that is said of their success and good management.

THE AMSTERDAM CINCHONA MARKET.

Our Amsterdam correspondent gives the following particulars with regard to last Thursday's sale, of which the result was announced shortly in our telegram last week: The cinchona auctions were very quiet all through, contrary to the general expectation. It is quite evident that the combined manufacturers were determined to keep down the price and to abstain from buying rather than raise the unit. The consequence of this was that the largest buyer, who generally has speculative orders in addition to those for his factories, was able to obtain one-third of the quantity offered without advancing the unit above 420c., against 410c. at the last sales. The unsold parcels are held for 450c. per unit. There is some idea that the quinine-makers' attitude is meant to frighten second-hand holders here (who hold about 18,000 packages) into accepting the small profit that the present unit would yield most of them, but it is not likely that any will be tempted. The richest parcel of bark in the sale was one of 20 bales of crushed *Ledgeriana*, analysing 8.51 per cent. This realised 36c. per half-kilo. *Druggists'* bark were in good demand at higher prices. This applies especially to broken quills and *Succirubra* chips and dust, which realised a unit of about 7c. Fine quills also found ready buyers, but medium varieties are quiet. We understand that, since the sales, bids have been refused on the basis of the sale-prices for several lots bought in at the auctions.—*Chemist and Druggist*, June 19.

THE DIAMOND JUBILEE OF INDIAN TEA.

As it is customary to recall just now the important events of the reign, it should be remembered that the Indian tea industry has flourished about as long as the Queen has reigned. The year 1837 witnessed, we believe, the first experimental efforts at tea growing in Assam, and it is needless to point out the developments which have followed. Tea has been cultivated in China for 2,000 years, in India but 60, and in Ceylon but 20 or so; and in the latest report by our Consul at Kiukiang he tells us "China teas are undoubtedly giving way more and more to teas from India and Ceylon." As for the consumption of tea, the increase during the Queen's reign has been extraordinary. Until three years before Queen Victoria came to the throne the tea trade was monopolised by the Dutch East India Company, and although we had tea in England as long ago as 1610 we were comparatively small tea drinkers before the present reign. Not the least significant feature of the Victorian era is this, that during it we have become the largest consumers of tea in the world. The United Kingdom itself consumes in the aggregate nearly as much tea as all other civilised countries combined.—*H. & C. Mail*, June 18.

EXTRACTION AND PREPARATION OF TALC.

Talc is extracted on a large scale from the granite mountain of St. Barthelemy, in the French Department of Ariège, about 32 kilometres (20 miles) from the main chain of the Pyrenees. The principal quarry, at Tremouin, is worked open-cast in three banks or terraces, each about 15 metres (49 feet) high. The best rock is of a bright white tint, and feels greasy to the touch when reduced to fine powder. The quarried rock is brought by a tramway to the end of the quarry in the Axiat Valley, and then by wagons for a distance of 19 kilometres (11 miles) to Luzenac, where 90-horse water-power is taken from the Ariège river. The mechanical preparation consists of drying in a rotary oven, breaking up small, grinding and sifting, the grinding being effected in mills with steel balls. The larger portion of the product, observes an Ingénieur des Arts et Manufactures, who has communicated these particulars to the *Chronique*

Industrielle, is converted into powder, only a small portion being sent away in the rough state, or cut into pencils for writing on metals. Besides its use throughout most parts of Europe and America, in soap and paper-making, talc enters into the composition of wagon-axle grease, while it also serves as an insulator for electric conductors.—*Journal of the Society of Arts*, June 18.

COFFEE PLANTING IN THE HAWAIIAN ISLANDS.

The cultivation of coffee in the Sandwich Islands is as yet in its infancy, but it has made such strides of late years that hopes are confidently entertained by the local Government that the industry will soon be placed upon a sound and important footing. It is said by Consul General Hawes, in a report that was received, lately by the Foreign Office in London, that the situation in Hawaii is (according to Mr. Charles Metcalfe, a planter of great experience in Ceylon and the islands referred to,) very similar to that of Ceylon* in the early days, when, owing to the want of experience, plantations were opened out in unsuitable localities, and when, owing to the neglect of considerations of soil or elevation, much money was lost, and the industry was brought into undeserved discredit. Conditions as to the labour supply, the distribution and amount of rainfall, the nature of the prevailing winds, and the range of the temperature, have to be studied at Hawaii as elsewhere. The soil is of volcanic origin, and is extremely rich and fertile, as Miss Isabella Bird long ago stated in her charming narrative entitled "Six Months in the Sandwich Islands." There is a vast area of land at elevations of from 500 to 2,400 feet that is believed to be admirably adapted for coffee, and only a small portion of it is under cultivation. The general lay of the land is westerly, so it commands plenty of sunshine. The rainfall is heavy, and varies from an annual average of 75 to one of 200 inches. The seasons are fairly regular, and they are favourable to coffee, as they insure the proper setting of the blossom, they facilitate pruning operations, and they furnish ample water for pulping and washing. The temperature rarely exceeds 85° in the shade. The Hawaiians being a self-indulgent and unreliable race do not make good field-labourers, and planters greatly prefer Japanese and Chinese when they are to be had. But immigrants from Japan and China are not as yet very numerous. The feeling of planters is strongly in favour of the monthly free-labourer; but the supply of suitable men is small and precarious. Contract labourers usually receive \$12½, and free labourers \$15 a month—rates which compare unfavourably with the scale of wages in force in Ceylon. On the other hand, the making of roads is not costly, owing to the easy gradient of most of the land. Then the coffee tree in Hawaii gives a yield greatly in excess of that of Ceylon, where a return of 672 lb. per acre on an average is considered a very good crop, whereas in the Sandwich Islands a yield of 1,000 lb. may, it is stated, be reasonably expected, or at the rate of 1 lb. per tree, which may be increased to 1½ lb. to 2 lb. by pruning and fertilising. The country is being covered by a network of fine carriage roads, which will greatly facilitate transport. Harbours on the western coast are numerous, and the landing places are available for almost the whole of the year. One District, called Kona, is peculiarly favourable to coffee, for it is blessed with perpetual rains, rich soil, a moderate rainfall, and regular season. The coffee grown there gives the large proportion of from 12 to 15 per cent. of pea-berry of fine quality.

Mr. Hawes quotes an estimate of the cost of establishing and maintaining a coffee plantation of 75 acres from the first to the seventh year. The pur-

chase of 100 acres of Government land will cost \$1,000. The Manager's salary is set down at \$1,200 a year. Six Japanese are employed in the first two years, nine in the four following years, and twelve in the seventh year. The estate should give 20,000 lb. of coffee of the value of \$3,600 in the third year; 60,000 lb., of the value of \$10,800 in the fourth year; and 85,000 lb., of the value of \$15,300, in the fifth year. This will suffice to clear all the working outlay up to date. This sixth year is calculated to yield 100,000 lb., of the value of \$9,985; and the seventh year 125,000 lb., of the value of \$11,680. At the end of the seventh year the balance at the credit of the plantation should it is said, be upwards of \$21,000. The above yields are stated to be far below what may be attained by thorough cultivation and fertilising. The estimates were compiled by the local Commissioner of Agriculture, and Mr. Hawes says that they may be relied upon as correct. He adds that fairly good coffee land can often be leased in the islands from private individuals at from 2 to 4 dollars per acre, for terms varying from 20 to 25 years, and that this method of obtaining land does not necessitate the holder becoming a denizen of the country.—*M. Mail*.

LEASING OF VIHARE LANDS.

A correspondent enquires:—"Do you know if there has been an extension of time for leasing Vihare lands allowed? I have an idea that there has been a Minute sanctioning leasing of such lands for 50 years. Can you say if I am right? Without such an extension few people would care to have such lands, at any rate for any permanent product such as coconuts."

Under the provisions of "The Buddhist Temporalities Ordinance 1889 and 1895," the Trustee of a Buddhist temple may with the sanction of the Provincial Committee, and for such rent and subject to such conditions as they shall deem reasonable, lease for any term not exceeding 50 years, all or any of the lands vested in him; provided that whenever a Trustee shall, with the consent of the Provincial Committee, be desirous of leasing any land for a period of more than 20 years, the sanction of the District Judge of the District in which such land is situated, shall first be had and obtained by him for that purpose. There is no later regulation that we are aware of.

GOOD OLD TIMES.—In the good old days of China tea some sixty years ago, the duty was 2s 1d per lb., and the range of prices per lb. in bond was as follows: Bohea 2s 10½, Congou common 1s to 1s 4d, strong 1s 6d to 2s, Pekoe kinds 1s 10d to 2s 8d, Souchong 1s 1d to 2s 1d, Caper 1s 1d to 1s 5d, fine Orange Pekoe 2s 6d to 3s 6d. The retail price of tea ranged in 1837 from 6s 4d to 14s. This was of course before the days of Indian tea. To those who remember the difficulty experienced over twenty years ago in procuring Indian tea from the shop of the tea retailer the following passage from the last issue of the *Grocer* shows the changes brought about by time. "As China is now making strenuous efforts to assimilate her produce to that grown in India and Ceylon, it becomes," says the organ from which we quote, "all the more necessary for British planters to turn out tea of extra good quality; for it is the undoubted excellence of their productions, adapted to the peculiar tastes and made to suit the palates of consumers at home, that has enabled them to achieve so signal a victory over their Chinese rivals as has been shown for many years past, and it is to be hoped that nothing on the part of the British tea-growers will be left undone to preserve their old reputation for successfully building up a gigantic industry, and thus maintain the prestige of their favourite product."—*H. & C. Mail*, June 25.

* Mr. C. Metcalfe, we feel sure, cannot recall the early days of Ceylon? We have no volcanic soil which makes a big difference, but Dumbura often gave over 1,000 lb. per acre of coffee.—*Ed. T.A.*

SCALE PESTS (ON COFFEE ESPECIALLY) AND LADY BIRDS.

At the last Annual Meeting of the U. P. A. S. I., attention was called to the success which had attended Professor Koebele's attempts to combat the scale pests which destroyed the Coffee plantations in Hawaii, and a Resolution was passed asking the Madras Government to communicate with the Commissioner of Agriculture, Hawaii, with a view to securing the services of Professor Koebele for a short period for the purpose of investigating the insect pests which attack coffee in Southern India. The Madras Government undertook to do this, and in a letter to the Commissioner of Agriculture, Hawaii, asked for information on the following points:—

(1) as to the results obtained from the experiments which have been conducted.

(2) as to the approximate cost obtaining a consignment of lady birds for experimental purposes in Madras and the source from which to procure such a consignment, and

(3) as to whether Professor Koebele could arrange to visit Madras for a short period for the purpose of investigating the insect pests which cause damage to coffee in the Madras Presidency.

Should Professor Koebele consider such a visit to be practicable, what salary and allowances he would consider sufficient remuneration for his services and on what conditions he would undertake the visit.

The following is the reply received from the Commissioner of Agriculture and Forestry, dated Honolulu, 3rd March, 1897, and the Government Order thereon:—

Your communication, dated the 14th November, 1896, in which you make certain enquiries concerning the entomological work of Professor Koebele was duly received. I have delayed answering your letter until I could communicate with Professor Koebele who had departed from these islands on a mission to Mexico and Central America, in search of beneficial insects to send to this country. I can offer you no encouragement that Professor Koebele's services will be available for the Madras Government, at least for two or three years to come, as he is under an engagement to this Government and to the Hawaiian Sugar Planter's Association, each paying one-half of the salary and expenses. The salary paid to the Professor is \$3,000, or six hundred pounds sterling per annum and all travelling expenses. Your first question, as to the results obtained from the experiments which have been conducted, I beg to answer as follows:—Before the engagement of Professor Koebele, the vegetation of the Hawaiian islands was sorely infested by numerous coccids or scale insects, which were so destructive that any industry, except sugar growing, seemed impossible. Particularly were the coffee trees infested with a terribly destructive scale insect (*Pulvinaria psidii*). The tree could not ripen its fruit, the berries turned black and dropped off long before they became ripe. *Tetranychus telarius* (red spider) was also present as well as several other destructive scales infesting coffee trees. The outlook for the coffee planter was gloomy indeed, and no one had the courage to start a new plantation and it seemed but a question of a short time when the industry would cease to exist in this country. Now, all is changed, the coffee trees are free of scale pests and blights, and new plantations are being started all over the islands. This wonderful change has been accomplished by the introduction in this country of the natural enemies of the scale pests that were present. The work of finding these natural enemies and sending them to this country was entrusted to Professor Koebele, and well has the work been done. The Professor has sent us beneficial insects from California, Australia, Ceylon, China and Japan and these keep our vegetation practically clear of scale pests. The Professor is now on a mission to find and send to us parasites and beneficial insects for cut-worms

and caterpillars that are injurious to sugar-cane, pastures and garden produce.

Question (2) as to the cost of obtaining a consignment of lady birds for experimental purposes in Madras and the sources from which to procure such consignment—The cost of such a consignment should be but trifling—an experienced collector can collect many hundreds of lady birds in a day. The method of packing them for shipment is to place the lady birds in small, practically air-tight wooden boxes, in which some slightly moistened moss has been placed; the boxes should then be wrapped in oil cloth so that no outside moisture can penetrate to the boxes. In order to safely carry the lady birds on journeys of over one week's duration, they must be carried in a temperature of between 30 and 40 F., this temperature can be found in the cold storage or ice-room of all passenger steamships. If transshipment from one steamship to another is required on the journey, a trustworthy agent should be on hand to make the transshipment without delay, for if the lady birds are once thawed out it is fatal to make them cold again. In this manner they can be safely carried on journey's occupying from one month to six weeks. As to the source from where to procure the lady birds, I am afraid that my advice will be of little service to you as I am not familiar with the coccids or scale insects affecting the vegetation, of Madras, if there are any of the *Dactylopidis* present, the *Cryptolaemus montrouzeri* will surely feed on them. Australia is the nearest country that can furnish that valuable lady bird as well as many other useful coccinelladae. China and Japan also have many indigenous species, some of which have proved of great value to these islands. I would strongly advise against the wisdom of relying on the importation of one or two shipments of lady birds and judging from the effects of these importations as to what can be accomplished in this branch of applied entomology. There are over 1,700 different kinds of coccinelladae or lady birds catalogued and probably many hundreds yet undiscovered, and all are, with very few exceptions, coccid or scale feeders, some such as the *vedalia cardinalis* will feed only on one scale, while others as the *Cryptolaemus* will feed on several. In order to obtain the best results, all countries within reach of a month's or six weeks' journey, should be explored for the beneficial insects they can furnish, and the work should be entrusted only to a skilled entomologist, one who has made the life habits of beneficial and injurious insects a special study. While all countries have their beneficial insects, they also have those that are injurious, and if the work of collecting is done by a person not thoroughly competent, injury instead of benefit might result.

As to whether Professor Koebele could arrange to visit Madras for a short period for the purpose of investigating the insect pests which cause damage to coffee in the Madras Presidency—In reply to this question I beg to say that I have communicated a copy of your letter to Professor Koebele and in reply he writes that he feels himself bound to the service of this country as long as we may require him. I am about to visit the United States and shall be absent from these islands for three months. During my trip I shall visit some of the United States agricultural experimental stations and shall meet several entomologists of established reputation; among them I may find one who would be willing to undertake the work of searching for and introducing beneficial insects to Madras; should you desire to learn the result of my enquiries I shall be glad to send the same on receipt of a request from you. Order—No. 351, Revenue, dated the 18th May, 1897.

Communicated to the Hon'ble Mr. H. P. Hodgson: The following letter acknowledging the receipt of the second of the papers read above and stating that the question of employing an entomologist from the United States cannot be decided until after the receipt of definite proposals from the Planters' Association, will be sent to the Commissioner of Agriculture and Forestry, Honolulu.—*M. Mail*, July 3.

ABYSSINIA : THE WASTE OF A
WONDERFUL LAND.
COFFEE AND CACAO AND "NUWARA ELIYAS."

(BY G. W. WARD.)

Harrar, May 4.

Idling here, in the midst of a luxuriant plantation, whose groves of coffee, and cocoa, and semi-tropical fruit-trees innumerable, separated by acres of sugar-cane and maize, pepper, cotton, and tobacco, are sunlit and noisy with a host of birds screaming, trilling, belling, cooing—it is easy to understand that I do not envy you who read.

Imagine an undulating region clear of jungle, for a long day's ride in any direction, blessed with a perfect soil, innumerable streams, game in just sufficient abundance, and willing labour at hand; imagine hundreds of square miles of soil capable of growing anything from an orange to a cabbage, so friable that a cat might draw the plough almost, and needing ten sickles where one hoe has been plied; picture to yourself such a land, if you can, and then mourn the fate of Harrar province.

I have spoken of the weary desert that lies between here and the Red Sea-coast; I have outlined the faintly-disguised designs of French politicians in regard to Harrar, and the unpardonable policy which led to the abandonment of this Eden by England when the Soudan was about to be evacuated; let me now utilize one of the many long hours that must be spent lazily, awaiting Menelik's passport to the beyond, in shortly describing the lost garden-land of north-east Africa—the paradise that an Englishman flung away fifteen years ago.

In all there may be thirty plantations around Harrar, though that is but a thousandth part of the possibilities. All practically were

CREATED DURING THE HALF-CENTURY

of Egyptian rule which England interrupted. They range in size from 200 to perhaps 2,000 acres. When the Abyssinians made the Galla country their eastern-most colony—which they did very promptly after the evacuation—they found Harrar and many of its gardens ready-made. Being beef-eating, mead-drinking warriors, like so many modern Norse men, they disdained agriculture, and (slavery being interdicted) but slightly appreciated the new-found treasure. A large proportion of the cultivated ground was therefore generously presented to the Greek and French community during the succeeding ten or twelve years. Here where I write, and all as far as I can see from this hill-side, was so given, by Ras Makonnen, in consideration of such valuable services as the dismounting a mitrailleuse, steady attendance for some weeks at his durbar: submission, uncomplainingly, to unjustifiable arrest by over-zealous soldiers; and things of that sort. The result is the extraordinary spectacle of almost the entire environs of the eastern capital of Abyssinia held by foreigners who mostly keep little grog-stores in town, know nothing of farming, and use the land chiefly as a place of recreation for Sunday outings. The only serious attempt at development is being made by a Cretan—the only man, too, who possesses title-deeds, and who, nevertheless, privately notified me that, if I excited the suspicion of the Ras by again applying for leave to visit his land, the land would probably be summarily seized,

WITHOUT ANY RED-TAPE BOTHER

about title or improvements. And he has spent some £5,000 on the plantation, mind you!

The richest soil in all Abyssinia, almost without a stone or a weed; with plentiful water and all the labour one wants at 6d a day; with no apparent foe or obstacle but wild animals and the long desert which lies between this and the sea—putting aside the insecurity of tenure under Abyssinian administration—it is an hourly marvel to me how England permitted such a territory to be thrown away, needlessly. Why—knowing nothing of planting, following primeval methods that an East or West Indian colonist would sneer at, the favoured landowner I have referred to draws already some 12s

net from each of his thousands of coffee-plants annually, not to speak of the other revenues from the great garden. And he hardly knows coffee when he sees it, and has no idea what to do with his cacao! His neighbour on each side is a store-keeper. On the hill opposite is the ground of a watch-maker. Fancy—only fancy!—what estates producing easily their £7 and £20 an acre annually, under the slipshod management of this batch of incompetent, insecure, indolent Greek and Armenian traders, might be worth in the hands of substantial, energetic, British colonists, who could rely on their titles being respected to an extent which no Levantine can in this despotic land.

I have seen the gardens of the Far East, and few could surpass in fertility these which encircle Harrar, given the same care. That this place is

UNKNOWN AND UNEXPLOITED

is easily explained: it would have been far less difficult to have obtained Ras Makonnen's leave to go a hundred miles in any direction, shooting, than to spend a few days of leisurely espionage in this Mount Pisgah.

This is not Abyssinia. It is hardly an Abyssinian colony. It is a derelict Paradise that Menelik has seized. Ten years ago it was his boundary. Today the frontier of Ethiopia is a hundred miles nearer the coast, and two hundred southward. The frontier is spreading, extending always, in whichever direction one looks. Your very latest London maps do not show it, by any means, or the believers in the eventual partition of Africa among three or four European

POWERS WOULD BE ASTOUNDED.

Even here the present boundaries are not known definitely. The western side is an enigma—the south a puzzle. South-east our sphere of influence is already invaded, and north-east Italy is limited once more to Erythrea. And Menelik has just ordered thirty Krupp cannon and a dozen mitrailleuses through a French agent. What does all this indicate?

Have I made the situation clear (to some extent, at least) in my later notes from this eastern gate of the leading North African independency? Fertile, rich in minerals, healthy, on the one side; governed in a mediævally barbaric style, with a dash of Thibetan exclusiveness; either the likely prey of a rival Power whose only interest is a foot of sandy beach at Djibouti, but who is avowedly to establish herself nearer the Nile source, or, if Britain misses her opportunity, a formidable obstacle against the spread of real civilisation beyond Khartoum if left independent—Abyssinia must be kept in view by our Foreign Office. To make her an ally will be a mistake—even the Little Britain party must see that her "protection" must inevitably follow the re-opening of the Soudan. And among other things British influence here will mean a dozen Nuwara Eliyas to our countrymen.—*Daily Mail*.

THE INDIAN TEA ASSOCIATION.

At the sixteenth annual meeting of this Association held at the Bengal Chamber of Commerce on the 16th June, the Chairman (Mr. G. A. Ormiston) in the course of his opening address referred to several important matters. One of the first subjects touched upon was the work of the Darjeeling and Doars Sub-Committee and satisfaction was expressed with regard to the outcome of representations made in regard to the waste land rules and leases. Road communications in the Doars do not seem to have advanced, but the Bengal Government has sanctioned a comprehensive scheme. Railway extension in that District is also much needed and Government is giving consideration to the question. As to the development of Assam it is pointed out that in that Valley alone it is estimated that the cultivable waste land is 6,700,000 acres not including the enormous tracts of reserved forests. The area

allotted to tea estates at present is 1,672,000 acres and so far as the Chairman can gather there does not seem to be any prospect of the waste land being brought under cultivation by the indigenous population. Alluding to the labour difficulty be argued that facilities must not be given whereby coolies would be enticed from the gardens, and that immigrative population brought in to cultivate these large tracts must be imported from other provinces, and not be drawn from tea. Government must take protective measures against famine, and look to a wide distribution of the population of congested districts, and Assam provides a large field for cultivation, and would add considerably to the revenue of that province. Subsequently reference was made to the interest the new Chief Commissioner is taking in the development of the Province, Mr. Cotton has journeyed through the whole Province, including Cachar and Sylhet, and if the many railways, tramways and communications are carried out in the way he desires, they would soon see the Province one of the most important and flourishing in Her Majesty's Dominions. Mr. Cotton has brought forward most prominently the necessity of branches of the Association being located in all districts, viz., Sylhet, Cachar and Assam, and that they ought to be in direct and constant communication with the Tea Association in Calcutta. In regard to the labour question, Mr. Cotton has given on behalf of the Assam Administration his full support to the scheme for the establishment of a Central Recruiting Agency, and expressed the hope that all interested would combine to make it a success;

In regard to the American Market Fund and Foreign Tea Committee it was stated that the results of the continued efforts being made in America by Mr. Blechynden, in conjunction with Mr. Mackenzie on behalf of Ceylon, could not but be viewed with satisfaction and it is added that it is desirable that every one interested should contribute their share towards the general interest, at the rate of four annas per acre on the area under cultivation, and half an anna per maund on the production. It is not laid down that the whole of the Fund will be spent in America as the American and Foreign Tea Committee would be prepared to support efforts to extend new markets in Russia, South Africa, and other places. In addition to these there is hardly another country which has not participated in some degree in the introduction of tea, and there are signs from all quarters of increasing consumption, to meet which, together with the further expansion at home, the additional production from India and Ceylon should not prove excessive. Thankfulness was expressed for the cordial co-operation of Ceylon in carrying on the good work in connection with the Indian representative in America, and the Chairman had no doubt that their united efforts will be crowned with success.

Mr. Blechynden attributed the slow progress of consumption there to the unwillingness of large firms to deal with Indians composed of small breaks, and, therefore, favour the facilities in handling long lines of China and Japan tea, but the Americans would, no doubt be able to adopt a remedy, and bulk themselves as is done at home. After a reference to the price of tea in Russia making the price prohibitive to the masses it was stated that it does not appear that we should fear so much from any change China and Japan may make in their mode of manufacture by the use of machinery, nor by the reduction of import

duty at home, but from the unnatural state of our currency giving our Eastern competitors a most important pull over us at present.

It is computed that the total acreage now under tea, both in India and Ceylon, is not far short of 800,000 acres, two-thirds of which is in India. With regard to the reduction in duty on tea at home it is stated that it has had the desired effect, and there is no reason to doubt that a further reduction will not result even more favourably to India, and they must get every assistance to be relieved of the additional out-turn, which must be expected from the increased area coming into full bearing. With regard to the bulking of teas it was stated that there should be a clear understanding come to, and although he had read a recent notice that the London Docks had plenty of space, and would give any further accommodation required for the increased importations to bulk a larger proportion of tea in London, they should ask the Committee of the London Association to look carefully into the matter, so that gardens might know what was best to do under the altered position recently suggested. In regard to handling of packages at the Tea Warehouse and Jetties, it was satisfactory so far to know that the Special Committee appointed to inquire into the treatment the tea had to undergo while in the hands of those they entrusted with their care, had had good effect, and he would only suggest to the next General Committee, not to relax their vigilance in seeing that the tea received every care in handling. After allusion to the necessity for an improved tea chest and the appointment of an agricultural chemist, it being stated that if the tea bush receives proper treatment here can be no reason to doubt but that the plant will be long-lived, mention was made of the value of prizes for individual research. Reference was next made to the prospect of a Planters Ward in the general hospital and the necessity for a Pasteur institute. From the annual report we quote as follows:—

At the time the last report was written, the General Committee had just issued a circular calling for further contributions on the same basis as in the year 1895. In that year the sum of £92,545 was contributed, representing a production of nearly 80 millions of pounds of tea, and including liberal contributions from the two Planters' Associations in Travancore, which have always evinced a practical interest in the efforts made to exploit the American market. The result of last year's circular has been still more successful, as the amount subscribed was £1,03,674 8-0, or an increase of about £11,000 upon the previous year. This included, as in the previous year, contributions from Travancore, and the increase was due to a special effort made by the Committee to induce gardens, which had hitherto held aloof to subscribe. The Committee do not feel that it is necessary to remark at any great length on the features of American campaign as carried on during the past year, as the American and Foreign Tea Committee in London issued an *interim* Report in February last, accompanied with copious extracts from Mr. Blechynden's Report for the year 1896, both of which have been widely circulated, and are also included in the Appendix. It will suffice to say that Mr. Blechynden, the representative of the Association, has continued to work vigorously in conjunction with Mr. Mackenzie, representing Ceylon, although their efforts this year have been carried on upon somewhat different lines, which are fully touched upon in Mr. Blechynden's Report. Advertising has been resorted to on a much more extensive scale than ever before and the system of giving subsidies, or grants-in-aid, was also established on a regular basis early in the year,

These subsidies were fixed, as a rule, at one fourth of the amount each firm was itself prepared to expend on advertising, demonstrating and otherwise pushing its own brands of Indian and Ceylon teas, and Mr. Blechynden points out that it would have been practically impossible for him by his own efforts, to have covered the large area worked during the year by subsidised firms at Food Shows, Bazaars and Grocery shows Mr. Blechynden has also done considerable amount of travelling, both in the States and in Canada, and has again made use of the varied means of bringing British-grown teas before the American public which are now familiar to anyone connected with the tea industry. The Committee in London have decided—and in this the General Committee here agree with them—that bearing in mind that the present year's crop, both for India and Ceylon, is again likely to show a substantial increase, there should be no relaxation made at present in the efforts which have hitherto been rewarded by so much success, and a circular has accordingly been issued, asking for farther contributions on the same basis as last year, viz., at the rate of four annas per acre on the area under cultivation, and half an anna per maund on production. The Committee trust that the present levy will show a still larger amount of subscription than the last, and that many of those who reap the benefits of the efforts made but who have not hitherto subscribed will send in contributions. The usual statements of accounts are annexed to this Report, showing receipts and expenditure in Calcutta, London and America.

A SCIENTIFIC OFFICER FOR THE TEA DISTRICTS.

The Committee regret that the proposals in connection with this matter, which was referred to in the last Report under the head of "Mitigation and Prevention of Insect Blights," are for the present in abeyance. On the 15th June 1896 the Committee issued a Circular to members, which summarised what had been done up to that time and asking for the views of members at an early date. The Committee were specially anxious to ascertain whether the project was likely to meet with a sufficient amount of support to warrant them in making an appeal to the tea industry generally for the requisite funds. The matter was also referred to the Committee of the Association in London, and was brought before their members at their Annual Meeting, at which it was found that there was a considerable divergence of opinion among members as to the advisability of going on with the project, the importance of which, however, was generally recognised. Reference is also made to the prospects of trade in Persia and Afghanistan.

The following information was supplied by the General Committee to the Secretary to the Chief Commissioner of Assam for insertion in the Annual Report on tea culture:—

	As. P.
Avg. price per lb. of Assam Valley tea in 1896	8 3
" " " " Surma " 1896	6 10
	lbs.

Outturn of tea in Assam Valley in 1896 61,153,793
 " " " " Surma " " 1896 47,000,973

These figures show an increase of about four millions of pounds in the production of the Assam Valley and of about six millions of pounds in the production of the Surma Valley.

The total planted area represented by the Association during the year is 275,445½ acres. This shows an increase of 10,307½ acres on the previous year, but the total area under cultivation is still a long way from being reached. The year's subscriptions at the rate of one anna per acre amount to R17,215-5-6, of which, however, only R16,219-12-6 were realised up to the 28th February, and, consequently, only this latter amount can be included in the accounts, the balance, however, having since been paid. The revenue account, notwithstanding the increase in the amount of the monthly contribution to the Chamber, shows a surplus of R2,139-7-10, and the Commit-

tee had a balance in hand on the 28th February 1897 of R17,926-4-7 less sundry liabilities amounting to R1,584-5-9. The Committee remitted to the London Association on account of the expenses of the London Office the sum of £200, the equivalent of which, R3,141-1-8, is debited to the revenue account, and has been provided, as usual, out of ordinary income.

We have next to refer to the speech made by Mr. H. D. Ashton in moving the adoption of the report. Amongst other interesting facts he mentioned that in the previous year the tea crop within what he described as the jurisdiction of this Association, amounted to 100,000,000 lb. more than in 1881-82 when the Association came into existence. When he examined the expansion of the Association as apart from that of the crop as a whole, the result did not appear to him so satisfactory. In 1881 the crop was returned as 47 millions, in 1896 as 148 millions; in 1881 the Association membership represented 103,000 acres; in 1896 275,000 acres, and he was told that the acreage under tea in Northern India last year might be estimated at 400,000. Taking this as correct they got an average out-turn of 370 lb. per acre, and applying that figure to 1881 there must have been 127,000 acres under tea to produce a crop of 47 millions. Therefore in 1881, 103,000 acres out of 127,000 supported the Association, and in 1896, 275,000 out of 400,000. Thus in 1881 about 82 per cent. of the whole acreage subscribed to the Association and in 1896 only 68 per cent.—not a satisfactory circumstance. He was aware that these figures were only a rough estimate, but they indicated at least that the Association had not expanded so rapidly as the Indian Tea Industry, and as he was of opinion that the work of the Association was thoroughly representative and goes to benefit the industry as a whole, he was necessarily also of opinion that those gardens which did not subscribe were evading their share of a burden that should be borne by all,—this being due to some misapprehension as to the objects and scope of the Association. Labour questions were only a part of the work of the Association and that work increased rapidly year by year in quantity and variety.

In supporting this motion Mr. G. G. Anderson referred to the efforts made to exploit the American Market. The past year's operations were, he was of opinion, distinctly encouraging but they must be unceasing to give their produce a firm hold on the American Market. The campaign must be carried on vigorously, as they had an energetic and enterprising competitor to contend with and one who had not only had for years the command of the market, but who was evidently prepared to go to some considerable monetary sacrifice to maintain the monopoly so long enjoyed. Vigorous efforts would have to be made to maintain and consolidate their position in America, not to mention extending their operations in that country and he could only hope that the further levy which had been called would receive the most favourable consideration of all concerned. The total shipments to Great Britain last year amounted to 132½ millions lb., and the quantity available for shipment this year was estimated at 138½ millions lb. and as similar increases might be expected yearly, he was afraid that, unless fresh fields were opened up, they would have to face a surfeited market in the near future. The speaker then proceeded to advocate the Central Agency Scheme for the supply of labour,

The Labor question had been receiving the attention in Government, and amongst other suggestions the peopling of Assam by the surplus population of other Provinces was one deserving of very serious consideration. The Hon. Mr. Turner referred to the handling of tea at the jetties and warehouses and pointed out how difficult it was when coolies had the handling of packages, to make them use that care they should use, and it was only by putting on extra European supervision that this could be done. That had been done and he thought with satisfactory results. A resolution was unanimously carried that the rate of subscription for the current year from each garden belonging to the Association should be one anna per acre under cultivation.

EXPERIMENTAL AND BOTANICAL GARDENS, ANURADHAPURA.

I was agreeably surprised to find cacao doing so well in the gardens. The conductor, Mr. Gooneratne, tells me that last year he gathered the largest crop.

The oranges have done fairly well. From the garden I have distributed both in the town and amongst the villagers on my circuits jak, Liberian coffee, cacao, and other plants.

A larger number of fruit trees should be grown for the free distribution amongst the villagers; it is useless to expect payment, for the villagers will not buy plants. Free distribution will, I feel sure, do good, and I fully endorse what Mr. Nevill stated in his report for 1893:—

The gardens here, if to be of any use to the Province, should introduce and test the varieties of well-known fruit trees and vegetables grown elsewhere in Ceylon as well as introduce new kinds. Little nurseries should be made of trees useful for food or affording by profit or luxury an incentive to careful home culture by the peasantry. Soursops, pomegranates of better quality than now exist, oranges, limes, even country damsons, ugrossa plums, West Indian papaws, and all such fruits could be sown on small plots of ground for distribution to the villagers.

The eucalyptus trees are doing well. The mahogany trees in the town look better than they did since I had them manured, and I dare say the extra amount of rain last year has helped them. There are some very fine mahogany trees in the Government Agent's grounds, so that it is fully established that this tree will thrive here.—*Mr. Byrde's Ad. Report for 1896.*

CACAO CULTIVATION IN CEYLON.

THE HARDIER KINDS AND AN EXPERIMENT IN GRAFTING SUGGESTED.

MR. E. E. Green sends us the following interesting note:—

"There seems to be little doubt but that the red variety of cacao is less suited to our climate than the Forastero stock which has a more vigorous growth and resists to a great extent all diseases and blights. Agriculturists all over the world seem to be turning their attention more and more to the cultivation of disease-resisting varieties of plants. In this connection you should note Prof. Marshall Ward's remarks in the last number of *Nature* (June 10, 1897, p. 122, lines 14 to 33). It would also be interesting to try the effect of grafting the more delicate 'red' on to the hardier 'yellow' stock."

From *Nature* we take over the following portion of Prof. Marshall Ward's review of a book on the "Diseases of Plants," by Dr. Tabeuf, which is given the first place in the weekly scientific journal:—

One of the most striking and important features in this new book is the far too meagre note on "selection of hardy varieties"—the word "hardy" does not accurately translate the original. From all sides we are now hearing that different varieties of vines, potatoes, wheat, etc., show different disease-resisting powers, and Tabeuf says, "An important method for the protection of plants from disease . . . consists in the selection and cultivation of varieties and species of plants able to resist the attacks of parasitic fungi."

The very brief account of what has done with the vine, and the reference to what has been discovered about wheat, will only leave the reader hungry for more information.

In Eriksson and Henning's exhaustive volume on wheat-rust—to which I can discover no reference here, the author confining his remarks to a note they published last year in the *Zeitschrift f. Pflanzenkrankheiten*—the student will find that as matter of fact some varieties of wheat suffer little, and others much from *Puccinia*.

I remember being strongly impressed, in 1880-81, by the varied differences between the *Hemicilia* on coffee and that on *Cathium* in Ceylon, and even then threw out the hint that the former had been derived from the latter; but the comparative immunity of *Coffea Liberica* as contrasted with *C. Arabica*, suggested that it was not impossible that a disease-resisting coffee should be found.

The subject is complex and bristles with difficulties; but that is no reason for hesitating as to the experimental inquiry; and indeed it has already been commenced in several countries, as the reports from Australia, America, and elsewhere show.

Another feature of interest and importance in Von Tabeuf's book, is the chapter on "preventive and combative measures," involving the treatment of diseased plants by means of chemicals. Here, again, I notice a lack of attention to the English literature: Berkeley, and others of our countrymen, had experimented with sulphur in various forms, long before most of the authorities mentioned had taken the matter up. Still, it is quite true, the introduction of Bordeaux-mixture, and its employment on the enormous scales adopted in France, Australia, America and elsewhere, have taught us much, and suggested more. It is a common mistake to suppose that the intelligent application of remedial measures to plant-diseases does not pay—there are plenty of witnesses to the contrary; but, unfortunately, school and university courses generally have allowed of so little attention to the knowledge that must be utilised in carrying out such measures, that even skilled farmers, foresters, and other cultivators of plants, have to enter upon these experiments quite unequipped for carrying them out properly.

Tabeuf's chapter on the "economic importance of diseases of plants" may be cordially—if sadly—recommended to all who are interested in the very necessary extension of technical education by the institution of agricultural schools and colleges. He quotes the losses due to the Californian vine-disease (1892) at 10,000,000 dollars; in 1891 the wheat-rust cost Prussia over £20,000,000, and Australia something like £2,500,000. Even allowing for large exaggerations—though reports from Sweden, India, Ceylon, the West Indies, and elsewhere suggest similarly large losses from fungus epidemics—in these estimates, it is evident that we have here to deal with the annual losses of which even a saving of a very few pounds per cent would be worth consideration; and the comparatively meagre experiments to hand hold out hopes of much more considerable saving, if steps are taken in time, with a due and intelligent knowledge of the problems to be faced, and the methods of facing them.

TEA-GROWING IN JAPAN : MR. BALLARDIE'S VISIT.

Seeing his whole absence has only been a little over three months, and that he visited Hongkong and Canton on the way going, and Shanghai on his way back, Mr. Ballardie had only a few weeks to give to Japan. The favourite route was followed, calling at Nagasaki, passing through the Inland Sea to Kobe, thence round to Yokohama and from there into the interior, visiting most of the places of note and attaining at one place an elevation of 5,000 feet above sea-level. All was very enjoyable notwithstanding occasional uncertain weather.

At Ugi, Mr. Ballardie was in the centre of the tea-growing districts; but unfortunately it was the season for pruning—done by women and youngsters after a very rough fashion with big knives, just as if hacking into a hedgerow—and very little plucking was seen. What he saw, however, was exceedingly coarse, and the cultivation is chiefly in garden style, though there are some considerable areas, kept in good order. One peculiarity was the artificial shade provided for the tea in pandals—shelter from frost in winter and spring perhaps, but also to induce tender buds. At Kobe, Mr. Ballardie was in a "Hong" employing some 500 coolies preparing tea,—withering in the sun, then firing, artificial facing and packing. Everything is very primitive and until the Japanese learn to pluck more carefully and to use machinery, they cannot do much. Mr. Ballardie is surprised more do not visit Japan; and yet a round dozen from Ceylon met in a local hotel one day including Messrs. Anstruther, Hadow, Major and Mrs. Lowry. He also saw Capt. and Mrs. Bayley in passing through.

NEW AREAS OF CULTIVATION IN N. C. PROVINCE.

Of the 775 acres of land sold during the year about 500 were opened. The sum total of the sales amounted to R13,348. No large blocks of land were sold; nearly all were small lots below village tanks, and realized an average of R17-21 per acre. This is satisfactory, for what I wish to encourage is the purchase by villagers of lands below their village tanks. In most cases the villagers have as much land as they can cultivate; as the restorations of tanks progress the sales of lands should also increase. What is chiefly wanted now is more population and more enterprise, and though some of my predecessors objected to the low-country Sinhalese coming amongst Kandyan villagers, there can be no doubt that there is more go in the low-country man, and that his enterprise stirs up his more apathetic Kandyan brother, and that he really does good. There seems a greater inclination now to grow coconuts, and I hope soon to be able to dispose of some high lands for coconut cultivation to some enterprising low-countrymen.—*Mr. Byrde's Administration Report for 1896.*

THE HURLEY-BURLEY WIND AT THE KNUCKLES!

(From a Planter.)

If in some places there be a question as to the want of energy in the present S.-W. monsoon, it is not at the Knuckles that they dispute it. There, at present, there is wind enough for any half-dozen ordinary districts in Ceylon, with a margin over to restore the lost character of any suspected monsoon to regulation vigour. The configuration of land with its deep and long valleys, up which it can rage, allows of more than justice to its excessive boisterousness. When

the wind is in a playful mood you have to furl your umbrella and put the strap of your hat under your chin; but when it wakens to real earnest, you have got to stop and hold on, if you chance to be on a ridge. Coolies have been blown over lately when plucking; one factory had over sixty panes of glasses blown in, in a squall; bungalow windows have been banged open which had been thought to be securely fastened;—but the crowning feat of the roaring element has been causing a flush to disappear, and making the S. D. to look foolish, wandering about looking for it! When he reported to his chief that there was no need for pluckers that day, as the flush had been blown, he expected to be denied belief; but the P. D. had experience of what a raging element the wind was in those parts, when it got anything like "a fair field and no favour" and knew besides that "truth was often stranger than fiction." Galvanized sheets flying about in the squally days of the S.-W., are common enough, and the visitor from more sheltered districts has disturbed nights, as the wind rages around, and threatens to pull everything down. All the same, it is fine healthy bracing weather, and the tea is looking fit for anything, waiting only for a chance.

THE AMSTERDAM CINCHONA-MARKET.

Our Amsterdam correspondent writes, under date of June 23:—"Today the quantity of cinchona-bark put up for auction on July 15 has been made known. It amounts to 258 bales, 53 cases of Government bark, and 4,770 bales, 524 cases of private bark; total, 5,023 bales, 577 cases, which is a fairly large quantity. Besides this quantity the stock in first hands only consists of 1,301 cases Government bark and 238 cases private bark, which is the smallest we have known for years. There are rumours that the export from Java for June will be large. These are based upon the applications made for space in the steamers at the beginning of the month. A few parcels of *Druggists'* quill have been sold privately since the auctions at somewhat advanced prices. The buyers for *Manufacturing* bark, however, are very reserved, and no business has been reported."—*Chemist and Druggist*, June 26.

FORESTLAND FOR SALE ON THE ANAMALAI HILLS, COIMBATORE.

WHY SHOULD PLANTERS GO TO SUMATRA, JAVA,
OR EVEN THE STRAITS?

We direct attention to an advertisement from the British Collector of Coimbatore elsewhere. Eighty square miles of hillcountry in the Anamalais are declared to be available for the selection of suitable forestland by planters of tea, coffee, &c. We give the following information from Balfour's "Cyclo-pædia," new edition:—

ANIMALLY, literally Elephant hills, a mountain range in the collectorate of Coimbatore, in the southern part of the Peninsula of India, and in the Travancore dominions, extending from lat. 10° 13' 45" to 10° 31' 30" N. long. 76° 52' 30" to 77° 23' E., with peaks up to 8850 feet high. There are small scattered colonies of the Kader, the Malai Arasar, Pul, yar, and the Maravar races. The Kader are open independent, straightforward men, simple, and obeying their Mopens or chiefs implicitly. They are of small stature, strong built, active, with woolly hair, and something of the African features, and file their front teeth to a point. The women wear enormous circles of pith in the lobes of their ears, which they distend down to their shoulders. A black monkey is

their greatest dainty. The Malai Arasar are taking to agriculture. The Pulyar are demon-worshippers. The mountains are covered by valuable forest trees, and at one time were worked with an annual profit of about 50,000 rupees a year, and there are many beautiful woods suited for turnery. The wild animals are the elephant, tiger, leopard, bear, hyæna, wild dog, bison, sambur, spotted and harking and hog deer; also the wild goat.—*Lt. Col. Hamilton in literis; Imp. Gaz.*

COIMBATORE district occupies an area of 7,432 square miles, over which about 7,000 villages and hamlets are spread, possessing a population of 1,763,274 human beings. It has but little rain. The produce is grains, mostly of the dry description, cotton, sugar, tobacco, and hemp. The climate is warm, and not unfrequently oppressive, being completely hill-locked. The Annamallay Hills are in the S.W. border of Coimbatore, and are richly clothed with valuable forests, with many elephants; and some of the lower hill ranges from the Neilgherries, between which is the valley and gap or pass of Palghat leading to the western coast. The Guzzlebutty pass leads up the deep valley separating the Neilgherry Hills from Collegal.

Coimbatore land is many times valuable than it was forty years ago: and wheeled carriages, which were 603 in 1846-7, in 1867 were 4,500.

"Little rain" must refer to the lowcountry rather than to the hills.

CACAO CULTIVATION AND DISEASE AGAIN.

We draw attention to an interesting Correspondence sent to us, for publication elsewhere by one of the younger generation of planters, whom we are glad to see following the example of our "planting pioneers" in taking a thoughtful practical interest in their profession. Men of this stamp, far more than capitalists even, constitute the mainstay of the continued prosperity of the planting enterprise and the Colony. Mr. Greig is not alone in the view he has taken of the evils attending free "skering": one of the very oldest of our cacao planters gave a word of warning on the subject some time back. Meantime, the sample which Mr. Green has given of the views of Mr. Willis and himself, must make all look forward for the matured opinions of both gentlemen. The grafting of the valuable but delicate Caraccas or Red variety on the hardy Forastero, is one well worthy of experiment. We hear of one Ceylon plantation of Forastero in bearing, where there is not a trace of disease; but query whether the same extent of grafted trees would not be even more valuable. Grafting, however, is for the future; the immediate problem for solution is, how to save the already afflicted fields of the Red Caraccas Cacao in Ceylon?

COFFEE IN THE HAWAIIAN ISLANDS.

Coffee, according to the report of Mr. Consul-General Harris, is attracting much attention in the Hawaiian Islands, and promises to become an important article of export. Though yet in a somewhat experimental stage, coffee planting has nevertheless made great strides in the last five years, and "there is every reason to believe that ultimately the industry will be placed on a sound and profitable footing." Before that end has been attained, however, "it is not improbable that several failures and disappointments will take place from various causes." The situation at the present time is very similar to that of Ceylon in the early days, when plantations were started in all sorts of unsuitable places without any regard to soil or elevation, the result being that many estates were abandoned and large sums of money were lost before coffee planting could be called a success or a profitable investment. That the Hawaiian Islands are eminently adapted to the

successful cultivation of the plant seems to be assured by the numerous patches of wild coffee trees throughout the islands, but particularly in the district of Kona, in Hawaii; but whether they will produce trees yielding crops year after year which will prove remunerative to the planter, with the high price of labour as compared with other countries, is a question which remains to be answered. With regard to labour for coffee culture there is said to be much diversity of opinion. The best authorities are opposed to the contract system, which has been in practice in the past on the various sugar plantations, and is still greatly in vogue. The contract plan was the only one at first open to the planter that secured him means for controlling and retaining his labourers on his plantation, but it was open to many serious abuses, and has caused from time to time endless trouble and disputes. At present the feeling is strongly in favour of the monthly free labourer, and the Japanese as a class, when properly handled, are found to be steady, good workmen. The Chinese also make excellent field hands, but they are very scarce for such purposes. The native Hawaiian cannot be recommended, being by some authorities considered totally unfit as a labourer on a coffee plantation, as he is "most unreliable, and from his nature seems to abhor any employment which demands constant and regular attendance." Other authorities, again, have great hopes that he will become useful in the coffee fields, and that the more intelligent may ultimately, like the Japanese, be even trusted with pruning and planting. *H. and C. Mail, June 25.*

A TIN AND COFFEE COUNTRY. ALSO COCONUTS, FIBRES, FRUITS, RUBBER, &c.

(In Conclusion.)

I have written of coconuts and coffee as products to be largely produced in the near future, but have said little about another product, "padi" (rice in the husk). It is at present grown only to a very limited extent. There are many thousands of acres lying waste on which it could be grown profitably, and the attention of Government is directed to irrigation works for those districts that offer the largest field for this industry, which is almost entirely in the hands of Asiatics, but not necessarily Malays, who stick to their ancestral fields and have little desire for pastures new. The fresh departure in this line is more by Chinese and Japanese, though the Tamils will no doubt eventually come in. The importance of the development of this industry is shown by the large quantity of rice annually imported up to the value of a million-and-a-half of dollars.

So far Perak has produced but little of the fibres of commerce, but the country has extensive tracts suitable in soil, and this, coupled with the heavy, well-distributed rainfall, has attracted the attention of those interested in Ramie grass, from which a beautiful fibre is produced by recent processes of decortication and degumming. As the quality of this fibre, and the processes by which it can be made fit for the spinner, are fully and successfully proved, there is every probability that Ramie grass growing and fibre producing will become a great industry in Perak and the other States. This fibre is of such excellence in strength and fineness, and the countries are so few where the grass can be grown profitably, by reason of droughts and climate, that it can hardly be overdone where the conditions are favourable.

Fruits of various kinds are grown, but two stand out prominently, the mango and the durian. The former is a delicious fruit, slightly acid, with a delicate but characteristic flavour. The contrast between the white of the fruit and the purple of the rind is as striking as it is beautiful. The durian, so far as smell is concerned, is indescribable. All Easterns who have ever tasted it crave for this fruit, though the odour is overpoweringly offensive and the taste to one who has tried it for the first and last time sickly and repugnant.

The liking, once acquired, like other habits, sticks, and the craving of the European becomes as strong as that of the Asiatic. The Malay, who owns some durian trees, builds himself in the fruit season a hut near the trees, perched high up on poles, and jealously guards them from all intruders, of which there are many of the animal kind. Bears, monkeys, squirrels, elephants, horses, cattle, goats, pigs, are all fond of this extraordinarily offensive but fascinating fruit. Tigers even, of which there are many in the country are credited with liking it; but that is a statement not verified, and it is supposed Stripes is more after the animals looking for the fruit than after the fruit itself. The produce of half-a-dozen durian trees will, with sundry other aids, keep a Malay family in comfort for a twelvemonth.

Pepper of excellent quality is produced largely in the Malay States, inside and outside the Confederation, and forms a considerable part of the export of that spice to Europe from the ports of Penang and Singapore. It may not be generally known that the black and white pepper of commerce come off the same vine, and that the white is made so either by steeping in water and rubbing off the black skin, or by decortication in special mills on the banks of the Thames. The latter is the white most prized by sausage and such like manufacturers. Sumatra and some other of the islands of the Eastern Archipelago also contribute to the pepper supply of the world, but none produce a finer quality than Perak, if we except a small Malay State called Trang, north of Keddah.

Nutmegs and cardamoms grow wild in the jungle, and are collected by the Malays for sale.

The indianubber tree (*ficus elastica*) is a well-known forest tree, attaining immense dimensions. The Malay has no idea of the slow process of milking the tree, but cuts it down, with the result that it is in a fair way of being exterminated. The same fate is threatening the gutta-percha trees, of which there are several varieties in the forest.

Sugar is grown extensively only in one district (Krian), but if there were any improvement in the price other districts could grow it as extensively. It is a cultivation much in favour with the Chinese and whatever they take up and gives a fair profit is sure to be persevered in and rapidly extended.

Tobacco has not been much grown, and lacking probably the finer soil and more suitable climate of Sumatra, where the finest known leaf is produced, it is not likely this product will ever be extensively grown in the Malay States.

Such are the prospects in Perak for the future advance of the State in tropical agriculture. The cordial support and encouragement of the Government is all that is needed to bring the State into the front rank for the production of most of the products mentioned, and probably for a good many more.

Having touched on the Perak of the past, of the present, and of the probable future, I may fitly conclude my remarks by the enquiry how this future that lies before the country is to be hastened and brought into operation. Not, I may answer, by the present system of an imperium in imperio, but by placing more power in the hands of the immediate and active head of the Confederation, and so enabling him to pledge a year's revenue of the combined States, say ten million dollars (as it will be a year hence if it is not now) for a loan to extend railways and roads,* proceed with irrigation works, and give encouragement to planters and settlers to engage in the cultivation of coconuts, coffee, padi, sugar, pepper, and all the other products of export and commerce.

The tin mining industry is so well established that it does not require special encouragement, but the gold mining, confined to the more isolated districts of the North of Perak and Pahang, requires extension of communications in these directions before any progress of consequence can be made. Were this reasonable power given the Resident

General, and a forward policy inaugurated, another thing would happen in a few years, the Malay States outside of and surrounding the Confederacy, Kelantan and Trengganu on the East, Johore on the South, Reman and Keddah on the North, would have to fall into line and come into the Bund, and so fulfil the dream of those who have foreseen the unity of the whole of the Malay States of the Peninsula for general purposes and the common good, under the sheltering wing of the great Empire of the East and the West. D. MACKAY.

—*Liverness Courier*, June 22.

PLANTING NOTES.

COFFEE GROWING.—"In a recent number of this magazine"—*The Hawaiian Planters' Monthly*—"a writer stated the cost of bringing a coffee plantation into bearing at ten dollars per acre. Ten pounds are nearer the average cost to the end of the third year, as may be seen in an article on coffee in this number." The article is one we copied from a New South Wales journal by Mr. C. Skelton. Our contemporary must remember that the cost varies with the charge for land, for labour and food. In Ceylon in old days the cost varied from £5 to £30!—the latter where the land cost R200 or more per acre.

A PARADISE FOR COFFEE AND CACAO.—Mr. G. W. Ward in the London *Daily Mail* gives a glowing account of the growth of coffee and cacao around Harrar in Eastern Abyssinia—see page 166. We presume Mr. Ward must have accompanied Mr. Rennell Rodd's mission to King Menelek. Of course, Abyssinia is the native home of coffee—so that we are prepared to hear of bushes or trees doing wonders in the way of crop; but it is a surprise to hear that cacao has also found a home in this region and is prospering exceedingly. It is certainly a great pity the district should not have good government and be open to British colonization. Perhaps King Menelek might be tempted by some exchange in the Soudan region?

SOAP MANUFACTURED IN FIJI—WHY NOT IN CEYLON?—A correspondent writes:—"Some weeks ago I wrote to you wondering why we had no soap manufactory in Ceylon, mentioning that such existed in far away Fiji. I enclose an advertisement cut out of a Fiji paper to show you what kinds of soap are manufactured":—

TO STOREKEEPERS, TRADERS, ETC :

LIST OF PRICES OF SOAP AS MANUFACTURED BY
SUVA SOAP AND OIL COMPANY.

	Per case.
No. 2 Blue Mottled	24/6
No. 1 Blue Mottled	26/-
Extra Special Blue Mottled	29/6
Household, No. 3	19/6
Household, No. 2	20/6
Household, No. 1	22/-
Golden Crown Yellow	23/-
Double Crown Yellow	24/6
Extra Special Yellow	29/6

To be obtained at above prices from all Merchants and from

THE SUVA SOAP AND OIL Co., Suva.
MESSRS. R. BENTLEY and Co., Levuka.

It is certainly rather absurd that a minor colony like Fiji should be making its own soap, while Ceylon with its widespread coconut plantations, pays away every year as much as R200,000 for soap. Half, if not two-thirds, of this at least ought to be saved by a local manufactory properly conducted.

* A loan of 5 million dollars has been sanctioned by the Secretary of State for railway construction in the Federated Malay States.—*Ed. T.A.*

“ASH OF COCONUT HUSK.”

THE VALUE OF SALT IN COCONUT PALM

CULTIVATION.

The following communication from our City Analytical Chemist, Mr. Cochran, although it may look, to the general reader, very dry and technical, is of special value to all cultivators of the coconut palm and in some degree to agriculturists generally. In the first place we are particularly pleased to have this important testimony—(added to that of Messrs. Davidson and Lepine whose figures in our “Manual,” however, referred to Jaffna peninsula)—to the value of common salt in palm cultivation. Only a few days ago, we were astounded to have a planter of experience declare to us that, in his opinion, salt was of no value to cultivators in Ceylon! He no doubt chiefly referred to cultivation otherwise than of coconuts, though he made no exceptions. We should like Mr. Cochran’s opinion as to the value of “sodium chloride” as a manurial agent, in respect of a variety of industries in the island, in order to justify the call—in next Session of our Legislature, we hope,—for leave to use untaxed salt (made useless for human food) for agricultural purposes. What Mr. Cochran says of the value of burning coconut husks and returning the ashes to the soil, ought to be made known and acted on far and wide, among the natives especially. At present these husks, in some cases, are being sold for less than their value as manure. It will be observed that Mr. Cochran evidently inclines to the view—though he has not yet demonstrated it by analysis—that the farther coconut palms are situated from the sea, the more likely they are to benefit by the direct application of “sodium chloride,” or common salt. Here is Mr. Cochran’s Report (which is just in time to be included in the new edition of our “Coconut Planters’ Manual” now passing through the Press):—

I had recently occasion to ascertain the amount of potash in coconut husk; and, not being able to meet with this information in any of my books, I determined the same in the ash of a ripe coconut grown in the neighbourhood of the sea. I further extended the examination to the other ingredients of the ash of the coconut husk, knowing that such an analysis was much wanted.

The nut was one of fair, if not large size; weighing with its husk and calyx 3.482 lb. The nut alone weighed 1.693 lb., so that the husk and calyx weighed 1.789 lb.

One-third of the husk, cut longitudinally with a third of the calyx, as the smallest portion that one could be certain of as representing the whole husk, was incinerated at the lowest temperature practicable. The temperature was kept low to avoid loss of the chlorides of the alkalis by volatilisation. For the same reason, I did not attempt to procure a white ash, but stopped the incineration while there was still an appreciable amount of unburned carbon present.

The crude ash, which amounted to 1.9381 per cent. of the husk, was analysed, and from the results obtained

the composition of the pure ash was calculated. The following were the results of the analysis:—

	Crude Ash.	Pure Ash.
	per cent.	per cent.
Carbon	4.57	—
Insoluble silica	3.00	3.14
Soluble silica	3.80	3.98
Lime	3.33	3.51
Magnesia	3.60	3.77
*Potash	29.06	30.45
*Potassium chloride	3.44	3.60
Sodium chloride	38.17	40.01
Phosphoric acid	1.18	1.24
Sulphuric acid	1.35	1.41
Carbonic acid, &c.	8.45	8.86
	100.00	100.00

* Equal to total potash .. 31.23 .. 32.72
 The crude ash from one husk amounts to 3.4673 lb. or 34.673 lb. per 1,000 husks.
 One thousand husks carried off the estate thus removes from the soil

Potash	10.823 lb.
Lime	1.172 ”
Magnesia	1.248 ”
Phosphoric acid	.409 ”
Sodium chloride (Common Salt)	13.235 ”

It is only necessary to multiply these figures by the number of thousand nuts grown upon an acre of land to ascertain the amount of these mineral constituents removed per acre. Thus, if they are multiplied by 6, the results may be compared with those obtained by Messrs. Davidson and Lepine, approximately, the terms used by them, viz.: “Salts of potash” “salts of lime,” not being quite definite. For comparison, I have changed pounds troy of Mr. Davidson’s into pounds avoirdupois.

MORE IMPORTANT MINERAL CONSTITUENTS, IN 6,000 HUSKS.

	Messrs. Davidson & Lepine.	From Seaside Nuts.
	lb.	lb.
Potash	252.00	64.968
Lime	55.00	7.032
Magnesia	—	7.488
Phosphoric acid..	2.27	2.451
Sodium chloride (Common Salt)..	28.117	79.410

It will be observed that there is no approach to agreement in the two sets of results except in the case of the phosphoric acid. Mr. Davidson finds that the coconut husk removes much more potash from the soil, than the entire amount of crude ash according to my calculation from seaside nuts.

I am not at all disposed to attribute all the difference in the foregoing sets of results to the cruder methods of analysis prevailing when Mr. Lepine made his determinations. I have no doubt differences of soil may account for part of it. I can well believe, from theoretical considerations, *e.g.*, that coconuts grown on a rich alluvial soil would have husks, the ash of which would differ in composition from those grown on sandy soil in the neighbourhood of the sea, in the direction of containing higher proportions of potash and lime and a lower proportion of common salt. It must be a satisfaction, however, to coconut planters to know that the coconut husk is not necessarily nearly so exhausting to the soil in the matter of potash as would be naturally inferred from the earlier analyses or estimates. At the same time, the ash of the husk is far richer in potash than any wood ashes I have analysed, and if the unit, *i.e.*, the hundredth-part of a ton of potash be valued at R2.50, a ton of the crude ash is worth for its potash alone R78, and, with the phosphoric acid, fully R80. It would take 61,604 husks, similar to the one dealt with, to furnish a ton of crude ash. One thousand husks, therefore, are worth for their potash and phosphoric acid alone about R1.24; or, to put it with greater accuracy, the ash of 1,000 husks is worth for its potash and phosphoric acid R1.21. This is without assigning a value

to the lime, magnesia and common salt. A few intelligent coconut planters consider it more economical to burn the husks and return the ashes to the soil than to sell the husks at rates, including delivery, of from R1 to R3.50 per 1,000 according to the distance from the estate of the Fibre Works. The results of my analysis quite confirm this view; and, as soon as it comes to be generally recognized and acted upon, the price of husks must rise, to the benefit of the cultivator.

It will be observed that the ash of the husk of a seaside nut is very rich in common salt; indeed, more so than the ashes of many marine plants. This led me to determine whether or not a considerable portion of this might not be simply a deposit on the outside of the husk from the sea air. A pretty large nut weighing 3.8 lb. was, therefore, washed with distilled water, and the amount of salt in the solution determined; but it only amounted to a little over one-tenth of a pound per 1,000 nuts. The coconut husk is not unique as regards the large amount of common salt in its ashes; thus, the ash of the root of the Mangold-wurzel contains 49.5, and the ash of the leaves of the same plant contains 37.7 per cent of common salt.

In order to ascertain how much common salt is really necessary to the proper development of the coconut husk, analyses would have to be made of well-grown husks from trees situated far from the sea.

The common salt in the husk is got rid of to a large extent in the process of steeping the husks. Thus, in the drainage water from pits on which coconut husks have been steeped in well-water, I have found, when analysing the same on behalf of the Colombo Municipality, chlorine equivalent to from 34 to 44 grains per gallon of common salt, the greater part of which must have come from the husks.

M. COCHRAN.

THE SAN PAULO COFFEE ESTATE CO., LD.

As everything bearing on tropical products interests us, we quote as follows from the prospectus of this Company:—

This Company has been formed to acquire certain coffee estates and other properties in Brazil, which Messrs. Schroder Gebrüder & Co., of Hamburg (the vendors to the Company), have agreed to acquire from the Conde de Sao Clemente, who has been in possession of the estates for many years. The property as described in the accompanying memorandum shows an area of about 9,225 acres (3,735 hectares) of coffee land and about 5,981 acres (2,541 hectares) of other land, and is situate in the province of Sao Simao, and is comprised of the estates of Santa Olympia, Sao Joaquim and Chanaan, which are contiguous and at a distance of six, 10, and 18 kilometres respectively from Serra Azul station, on the Mogyana Railroad. Messrs. Zerrenner, Bulow & Co., of San Paulo, in Brazil, reported upon the property at the request of Messrs. Schroeder Gebrüder & Co. A copy of their report accompanies this prospectus. From the memorandum and report it appears—

Approximately Santa Olympia contains 810 alqueires of coffee land and about 979,000 coffee trees; Sao Joaquim contains 236 alqueires of coffee land and about 232,300 coffee trees; Chanaan contains 497½ alqueires of coffee land and about 390,000 trees. In addition thereto there are at Chanaan about 1,000 alqueires, and at Santa Olympia 50 alqueires, of low grounds for other cultivation and pasturage.

The coffee plant comes into good bearing after the plants are six years old, and it will be seen from the following table that the plants are of various ages, young plants coming on in rotation:—

years old.	years old.
140,000 being 17	93,000 being 5
88,000 " 14	25,000 " 4
155,000 " 9 to 13	132,000 " 2 to 3
155,000 " 8 to 10	259,300 " 1 to 3

1,601,300 trees.

There is amongst the coffee land about 2,720 acres available for further planting. The estates are

equipped with dwellings, machinery, workshops and various appliances for the management of the estates, accommodation for labourers, and other appliances suitable for a large business, and on the property is a railway and a canal belonging to the estates.

The railway connects the estates with each other and places them in connection with Serra Azul Station on the Mogyana Line. The estate railway measures about 32 kilometres with branches and siding, and is used, not only for the carriage of produce of the estates, but also for the carriage of produce of surrounding estates, and arrangements have been made with the Mogyana Railway Company under which that company pays 8 milreis for every ton of coffee delivered at Serra Azul Station by the estates railway. The Company acquires the benefit of this arrangement.

As therein stated, the returns of coffee sent to Santos, and the amounts realised, after deduction of the expenses from the estates to Santos, are given:—

1894, 62,099 arrobas, realising 1,061,000\$00, calculated at the exchange of 7½d.—£34,813.

1895, 64,481 arrobas, realising 1,271,000\$000, calculated at the exchange of 7½d.—£41,704.

*1896 (approximately) 104,000 arrobas, realising about 1,700,000\$000, calculated at the exchange of 7½d.—£55,781.

*Since ascertained.

The 1897 crop, now being picked under very favourable conditions, is estimated at a minimum of 80,000 arrobas—a diminution in the yield as anticipated and explained in Messrs. Zerrenner, Bulow & Co.'s report—which further puts the future production at an average yield of 125,000 to 130,000 arrobas, owing to the increasing production of the younger plants, of which there are a large proportion.

125,000 arrobas at the present depressed price, 9\$200 per 10 kilos, equal to 13\$800 per arroba, would give	1,725,000\$000
Less expenses as hitherto incurred, 5\$900	
per arroba	737,500\$000
Would yield a net return of	987,500\$000

At the exchange of say 7½d £32,402

There are other sources of revenue arising from trading profits on commodities bought by the colonists and others in the neighbourhood—also from railway traffics on goods other than those carried for the Company.

The annual amount required to provide for the interest on the debentures now offered is £8,800

The amount required for the sinking fund is 4,000

The amount required to pay the interest on the preferred shares annually is 8,400

Total amount required for the present issue £21,200

Leaving a considerable surplus for contingencies and dividend on the deferred shares.

The Company has entered into a contract for the acquisition of the property and estates and the provision of working capital hereinafter mentioned, in consideration of the issue to Messrs. Schroder Gebrüder & Co. and the Conde de Sao Clemente, and their nominees, of the whole of the share capital of the Company, and the whole of the first mortgage debentures, all credited as fully paid up, or of the proceeds thereof, and the issue of mortgage debentures and preferred shares is now made on behalf of the vendors. The 15,000 deferred shares are held by the Conde de Sao Clemente, the present proprietor, the vendors and their friends.

The vendors agree to provide the Company with £10,000 sterling in cash for working capital, and to bear and pay all costs, charges and expenses whatever, including legal expenses, printing, advertising and brokerage, the investigation of title, and the transfer of the property and all stamps in England.

and Brazil. The purchase price has been fixed by the vendors, who have agreed to buy the property from the Condé de Sao Clemente, in consideration of cash and of deferred shares.

The properties are being worked on account of the Company from the 1st day of January, 1897, so that the Company is entitled to the crop now being gathered. Messrs. Zerrenner, Bulow & Co., of Sao Paulo and Santos, have been appointed agents for the Company in Brazil, and are arranging for the appointment of a competent resident manager.

The debentures are secured by a deed of trust dated the 9th day of June, 1897, and made between the Company of the one part, and Bruuo Schroder, Esq., and Walter Campbell, Esq., as trustees, of the other part, and which contains covenants by the Company, with the object of the debentures being entitled to the benefit of a specific mortgage on the coffee plantations and other immovable property in Brazil. The deed, of trust also provides that the debenture debt is to be a charge upon the Company's other existing properties, stocks, &c., as a floating security. Any new coffee plantations which the Company may hereafter acquire will not be included therein. By the deed of trust power is reserved for a prescribed majority to bind a minority of the debenture holders.

EXTRACTION AND PREPARATION OF TALC.

Talc is extracted on a large scale from the granite mountain of St. Barthelemy, in the French Department of Arriège, about 32 kilometres (20 miles) from the main chain of the Pyrenées. The principal quarry, at Tremouin, is worked open-cast in three banks or terraces, each about 15 metres (49 feet) high. The best rock is of a bright white tint, and feels greasy to the touch when reduced to fine powder. The quarried rock is brought by a tramway to the end of the quarry in the Axiat Valley, and then by wagons for a distance of 19 kilometres (11 miles) to Luzenac, where 90-horse water-power is taken from the Arriège river. The mechanical preparation consists of drying in a rotary oven, breaking up small, grinding and sifting, the grinding being effected in mills with steel balls. The larger portion of the product, observes an Ingenieur des Arts et Manufactures, who has communicated these particulars to the *Chronique Industrielle*, is converted into powder, only a small portion being sent away in the rough state, or cut into pencils for writing on metals. Besides its use throughout most parts of Europe and America, in soap and paper-making, talc enters into the composition of wagon-axle grease, while it also serves as an insulator for electric conductors.—*Journal of the Society of Arts.*

NEW AREAS OF CULTIVATION OPENED DURING THE YEAR IN MATARA DISTRICT.

The largest extension of cultivation has been in citronella. The high prices ruling early in the year, and probably the existence of contracts, led to good prices being realized at the Crown land sales, and induced private owners to open more land, and in some cases to extend their operations and buy in the Morawak korale, where there had been little hitherto. About 2,500 acres were planted in 1896. About 100 acres of tea were opened in the Weligam korale by natives and about 900 in the Morawak korale. In coconuts little, if anything, was done beyond small village patches of a few trees, and what I have previously referred to as planted by Mr. Le Mesurier.—*Mr Vigors' Administration Report for 1896.*

OPENING OF NEW CULTIVATED AREAS: S. PROVINCE.

A very small extension of the area under paddy was reported; all are turning their attention to tea, citronella, and coconuts. The Mudaliyar of

Gangaboda pattu estimates that there was an increase of about 500 acres under tea in his pattu; the Mudaliyar of Wellaboda pattu estimates the increase under the same product at about 400 acres. Citronella is advancing chiefly in the Talpe pattu; cinnamon in Bentota-Walallawiti korale and the Wellaboda pattu. The following table will show the principal products and the area of cultivation:—

Product.	Area in Acres.	Product	Area in Acres.
Coconut	94,000	Tea	7,760
Paddy	43,000	Cinnamon	4,680

Citronella being a comparatively new product finds no place in the Blue Book returns. This should be rectified.—*Mr. Wace's Administration Report for 1896.*

THE RUBBER INDUSTRY IN WEST AFRICA.

From a paper recently read by Sir Gilbert T. Carter, K.C.M.G., before the Royal Colonial Institute, we quote what bears on the Rubber industry, and the very pointed comments of Dr. Morris in the discussion which followed:—

THE PRODUCTS OF THE COLONY OF LAGOS.

This Paper would be incomplete without some reference to the products of Lagos. Until the year 1895 the colony may be said to have relied almost entirely upon palm oil and palm kernels, which formed the bulk of the exports. In that year, however, a flourishing rubber industry developed, a brief account of which will not be devoid of interest. For some years a considerable quantity of this valuable product had been exported from the Gold Coast, due to the efforts of Sir Alfred Moloney; and he had, so far back as 1882, suggested the possibility of a similar industry at Lagos. Through his initiative some experiments were made upon rubber-producing plants, but it is difficult to stir up the native mind to effort in a new direction, and no practical results followed. During my expedition to the interior, in 1893, I had noticed the prevalence of a tree, in certain parts of the Yoruba country, having a milky sap; but as the tree was unlike any other rubber-producing plant which I knew, I attached but little importance to it. At that time there was in Lagos a political prisoner from the Gold Coast, who used to visit me occasionally to endeavour to obtain my co-operation in getting his release. On one of these visits he told me that he had learnt, from some of his Fanti surroundings, that the same tree whence the supplies were obtained on the Gold Coast existed in great numbers in the neighbourhood of Ibadan. I at once asked him if he could get some people down from the Gold Coast who understood the process of collecting and preparing the rubber, promising, if he did so, that I would put them in communication with the European officer at Ibadan, to whom I would give instructions to have the men properly accredited to the native authorities, who, I felt sure, would be glad to assist them in an enterprise which would be a source of additional wealth to the country. He promised that he would do so, and as soon as practicable about forty Fanti rubber-collectors arrived from the Gold Coast. These men were despatched, as I had promised, and in a very short time samples of rubber were forwarded which convinced me that Lagos was on the eve of a very important addition to its exports.

A notice was issued apprising the merchants of the possibilities before them, and I will only add that my most sanguine expectations were more than realised. Indeed, the development of the industry was phenomenal. While, in 1893, the total export amounted to 5,867 lb., valued at £324 6s 4d, the following year it rose to 5,069,576 lb., valued at £269,893. Through the courtesy of the Colonial Office authorities, I have been able to obtain the figures for 1896, and learn that for that year the value reached the large total of £347,730. It is feared that unless means can be devised to prevent the trees,

from being over-tapped, their wholesale destruction will follow; but obvious difficulties are in the way of any satisfactory check in this direction, more especially as but little rubber is found within the British jurisdiction. I do not think, however, that the trees are destroyed to anything like the extent which is generally supposed. The tree is known as the "*Kickxia africana*."

EXPORTS.

It has been previously stated that the total exports for 1895 amounted in value to £985,595, and it will be interesting to see how large a proportion of this sum is distributed amongst the three main staples of export trade of Lagos. The details are as follows:—

Palm Kernels	£320,434
Palm Oil	205,553
Rubber	269,892

Total .. 795,879

When it is stated that out of the difference between the two totals no less a sum than £100,789 represents specie, exported mainly to West African ports, it will be understood how comparatively unimportant are the other local products. The bulk of the palm kernels is absorbed by Germany, the figures being:—

Germany	£227,556
Great Britain	92,877

The distribution of palm oil is as follows:—

Great Britain	£155,344
Germany	48,528
France	1,680

and of rubber:—

Great Britain	£166,343
Germany	79,999
Cape Coast.. ..	17,471
Accra.. ..	6,077

From this it will be seen that Lagos helps to swell the export of this commodity from the Gold Coast. It would appear that the process of drying the rubber is understood better in that Colony, and probably its improved condition pays for the double handling.

DR. D. MORRIS, C.M.G.: Not long ago we had the pleasure of hearing a Paper from Sir George Baden-Powell on West Africa as a whole. Now we have been favoured with an account of one of the most important Colonies in that part of the world. The Governors present have been specially connected with the wonderful development of West Africa. Taking only the rubber industry, Sir Alfred Moloney has told us how in the Gold Coast Colony in 1882 hardly any rubber was exported, and yet through his individual interest in the matter it is now exporting rubber to the value of £200,000. Sir Alfred mentioned £100,000, but the exact figures were £218,162 in 1893. It was important that capable and progressive men should be sent out to administer our Colonies, because they have it in their power to do more for their Colony than anyone else. Development is much more rapid when a Governor takes a real interest in the affairs of his Colony. In the case of Lagos its development has been most remarkable. For instance, the rubber industry in three years has risen from practically nothing to something like £300,000. Everyone who uses rubber in any way should feel grateful to Sir Alfred Moloney and Sir Gilbert Carter. In regard to the question of the future supply of rubber, companies are being floated, and a large number of people are saying, "If you plant anything, plant rubber." If, in a few years or so, rubber of the value of half a million could be raised in two little spots in Africa, I think the people who are advocating planting rubber all over the world should look more closely into the matter. We know that in Brazil the Amazon Valley and both sides of the Andes are largely devoted to the rubber industry. In Central America, Mexico, and other parts of the world rubber is likewise being produced as a forest product in large quantities. During the last twenty years the price, according to reliable statistics, has risen only a few pence per pound. Before we start planting

rubber in our own Colonies, and especially on land which can produce other things more valuable, we should be satisfied that the rubber industry is not likely to follow the cinchona industry, which has caused so much loss to planters in the West Indies, India, and Ceylon. The tree which has been the means of yielding so much rubber in Lagos extends probably right across from Sierra Leone to the mouth of the Niger. The tree is not unlikely to be found in extensive tracts in the interior of West Africa. It is needless to say that it should be most carefully preserved in all the British Colonies where it is found, because it is not fit to tap until it is of some size, and it cannot again be tapped for some time. No doubt many trees are bled too severely, and killed. There is, however, a great difficulty in regulating the tapping of these trees and preventing their destruction; but there can be no doubt that everything should be done by the authorities to preserve them.

THE PROMISE OF CHEAPER RUBBER.

("India Rubber World" June 10th.)

Bolivia's government has become very much alive to the possibility of greatly increasing the public revenue, and promoting public improvements and private enterprise, through the development of her rubber resources, and this is being attempted in many ways, including the admission of alien rubber-collectors on the same terms as citizens, which has not been permitted hitherto. There are yet many difficulties to overcome, but the example of the recent growth of Pará and Manáos, based upon the rubber trade alone, has not been lost upon the Bolivians.

An important steamer line has opened a new direct service to Iquitos, implying confidence in a largely increased trade with eastern Peru and the upper waters of the Amazon, the basis of which can only be rubber. Transportation facilities must exist before rubber-gathering can be developed, even in the richest districts. With sparse populations, indisposed to industry of every kind, the inducements to gather rubber must be definite. There must be frequent trips by steamers, trading stations with goods temptingly displayed, and collectors financially able to bring camps of laborers from a distance to supplement the work of the natives. Rubber comes to market from a new district in dribbles—a few pounds here and a few pounds there—and a large production is a matter of long growth. But this growth has been in progress so long in the region beyond Iquitos that more substantial returns are now to be looked for.

The work of actively exploring for rubber in Brazilian forests which have not yet been attacked is likewise proceeding, and renewed interest is being manifested in the rubber resources of Colombia, Venezuela, and the Guianas, not to mention the rubber-planting projects in Mexico and Central America.

In Africa only the completion of the Congo railway is needed to give a great impetus to a rubber trade which already has assumed large proportions and made of Antwerp an important rubber mart. With the natural obstructions to navigation removed, no doubt the government will be pressed to amend the present restrictive regulations, with the effect of opening the rubber trade to all comers and largely increasing the output from the forests which stretch from the mouth of the Congo to the headwaters of the Nile. Then the probability of the abundance of the *Kickxia africana*—the tree which yields the rubber of Lagos—all the way down to the Congo gives promise of sources of rubber unsuspected until lately. Finally, in Asia, recent investigations have impressed the authorities of British Burma with the great extent of rubber forests in that country. The trade in rubber there has been in the hands of Chinese merchants who have tried to conceal the extent of the supplies, but while they have insisted that the trees were disappearing, the yearly exports from Rangoon have increased. Now that the truth is beginning to be suspected, the Chinese traders are likely to find competitors in the field.

NEW AREAS OF CULTIVATION IN SABARAGAMUWA.

The rapid, perhaps too rapid, extension of tea plantations is remarkable. The area of the lev clearings for all produce is stated by the headmen at 3,800 acres, mostly for tea. The largest extent is 1,800 acres in Kadavata and Meda korales, *i.e.*, in the Balangoda planting district. In Atakalan korale the extension for tea is reported at 600 acres, chiefly at Madampe. In Nawadun korale about 600 acres have been cleared and in Kuruwiti korale about 300 acres.

The advance in the cultivation of paddy is represented by 144 acres, of which 131 was land under the Uggalkaltota irrigation channel.—*Mr. Moyses's Administration Report for 1896.*

LEGISLATION AGAINST WEEDS.

In Madras the State takes a benign concern in the destruction of weeds, namely, in the matter of cutting away the jungle-growth in the close precincts of villages, in which snakes are likely to find cover. The villagers are generally somewhat inert to the procedure, and the weeds, as far as the people are concerned may grow at will. None the less, the Government continues forcibly to urge the destruction of the weeds, and, even though for some reason or another, the deaths from snakes are greatly increasing in number, in spite of the efforts to the contrary, the destruction of weeds should tell if the thing were really done properly. In some of the United States the law is in serious force against weeds, not on account of snakes, but in the matter of agriculture. A bulletin of the Washington Department of Agriculture mentions that laws against weeds are found upon the Statute-books of as many as 25 States of the Union. In some cases, as in California, Delaware, and Kentucky, the law is directed against only a single species, usually the notorious Canada thistle. Other States, such as Minnesota and Ohio, proscribe as many as 14 species of weeds. The Canada thistle is on the black list in 21 out of the 25 States, whilst six States legislate against the Russia thistle. This "Canada thistle," by the way, is interesting—Canadian in nothing more than in name. It belongs to Great Britain, where it is known as the creeping thistle, growing to a height of some three or four feet, with dingy purple flowers. In some form or another, however, either in bales of merchandise, or otherwise, its seeds have followed civilisation round the world, all over Europe, into Asia, America and Australia. Weeds are peculiar things, and, like the rabbit in Australia, most weeds are more prolific abroad than in their own home, and the creeping thistle is a much greater nuisance in Canada and in Asia than in its original home. The Washington Department has calculated that one per cent. increase in the crops of the United States, such as might be obtained by the destruction of weeds at little cost, would represent the large total of \$17,000,000, and it urges that there should be a common federal law against weeds in general, though each State should necessarily be left to decide which are the particular weeds that need extermination within their own borders.

In India our agriculture is not yet crowded out, and the agriculturist soon gets rid of weeds when they interfere with his returns of rupees, annas, and pice. The mortality in human lives, however, is so great year by year from snake-

bite—and shows such a tendency to increase seriously—that it might be well perhaps if villagers were not merely 'persuaded' but could be 'compelled' to cut away the snake-harboursing jungle within a certain area round their houses or their villages.—*M. Times*, July 13.

SOME INDIAN POOCHIES.

The last volume of Indian Museum Notes relates, among other miscellaneous reprints and notes, to an exhibit collection of economic insects in the Indian Museum, to some new species of Indian beetles, aphids and other insects, to insect pests and Indian "forest flies," and to the common crow of the United States as an enemy to insects and so as an aid to man. The notes are accompanied by three full page photo etchings of several of the *poochies* described, beautifully executed by the Survey of India Office in Calcutta. The exhibit collection has been prepared with a view to illustrate the life histories of some of the more important "economic" insects, both injurious and useful, in the various stages of their development, the pests being arranged in accordance with the plants which they attack. Thus we find 17 different insects which are harmful to tea bushes and three to coffee, either as defoliators or borers. No illustrations of these pests are given, which is to be regretted, as they would no doubt have greatly assisted planters in detecting these their enemies at a glance. Mr. C. Kerremans describes a new species of (Buprestid) beetle discovered in the Dehra Ismail Khan District, which is very destructive to melons and cotton crops. He has dedicated this "very beautiful species" to the memory of the late Mr. Atkinson, and it will accordingly be known in the future as *Julodis Atkinsoni*. The beetle is minutely described, but it is not everybody who will be able to make much of the following:—"Julodis Atkinsoni, nov. sp.—Oblonga, convexa, apice subattenuata, supra viridi obscura, nitida, elytrorum fossulis thoracisque punctis aeneo-viridibus; subtus viridiaenea, segmento abdominis 2°, 3°, 4°, que nigro coerulei cinctis, ultimo irregulariter nigro-vermiculato; pedibus aeneis, antennis nigris;—capite granuloso, fronte antice subrugosa, vertice longitudinaliter rugata;—pronote convexo, transverso, grosse punctulato, punctorum, intervallis elevatis et irregulariter vermiculatis . . ." and so on for several lines. True, a translation is given, but even that is more or less unintelligible to the uninitiated. Mr. Buckton descants on two new species of gall-aphids in the North-West Himalayan region, one a homopterous insect which forms smooth rounded galls on the twigs of poplars growing at an elevation of 9,000, in the Valley of the Yasin river, and one which forms large galls with a rough surface on aspens at Bunji, on the road to Gilgit. Mr. L. de Nicéville has a note on the "Potu" or "Pipsa" fly which attacks men and beasts alike and whose bite generally causes intense irritation and sometimes death. It attacks the ears and eye orbits, and it is reported that when the Chakrata-Saharapur road was being constructed, numbers of the work people died from the effects of being bitten by these flies. Tea planters will appreciate Mr. E. Barlow's careful descriptions of certain tea pests, accompanied as they are by a plate showing five different species. As regards miscellaneous tea pests, Mr. Barlow says that four species of moth-caterpillars, one species of beetle and two species of scale-insects have been reported during the past year as doing extensive damage to growing tea-plants in India, none of which are mentioned in Mr. Cotes's "Insects and Mites Destructive to Tea." Mr. Barlow adds:—"As regards remedial measures, in the case of the caterpillars, drawings of the parent moths and of the cocoons were forwarded to the parties interested, in order that the pest might be searched for, recognised and destroyed. In the ships of the Indian Marine, it is, we believe, found possible to keep down even such nocturnal animals as cockroaches, by set-

ting boys to catch them, and there seems to be no reason why the same plan should not be successful in the case of such large tea-pests as caterpillars, cocoons, etc." Among other interesting notes in this number are those relating to the mango weevil, insects infesting croton plants, ticks infesting fowls, and the reprints, especially that referring to the formation of new colonies by *Termes incifugus*, and the crow as an insect destroyer. The 60 pages of which this number consists contain a quantity of valuable and interesting information.—*Madras Mail*.

NEW AREAS OF CULTIVATION IN THE HAMBANTOTA DISTRICT.

There was but little new land brought under cultivation during the year.

Ir. Magam pattu a tract of forty acres under Yodawewa was asweddumized.

In East Giruwa pattu Mr. Elliott, late Government Agent, Southern Province, commenced to cultivate the Walawe estate, but no new land was sown before the end of the year.

In West Giruwa pattu there was more laud than usual cultivated during the year, but none of this was cultivated for the first time as far as I can ascertain.—*Mr. Hopkins' Administration Report for 1896*.

FOOD SUPPLY IN MATARA DISTRICT.

The paddy crops reaped during the year were fair average ones. The outturn was about the same as in 1895, viz., 750,000 bushels. This was supplemented by imported paddy for the estates and portions of the district to the extent of about 10,000 bags. The figures are practically the same as last year. In the Morawak korale and portions of the Kandaboda pattu the extent of land capable of irrigation is small, and the inhabitants have for years been dependent on fine grain of different kinds to supplement their food supply. These crops were average ones last year. There was however money to be earned for clearing and cultivating citronella estates, and the villagers were thus able to buy better food, and did not attempt to grow much last year. The crops of coconuts, jak, breadfruit, &c., were very good, jak and breadfruit being especially plentiful. Vegetables of the common sort are grown through most of the district, but not in large quantities, and taken to the communal markets, where they find a ready sale. Fish is taken by coolies to the markets at Tihagoda, Kirinda, Hakmana, and Kamburupitiya. There is practically no room for any extension of paddy cultivation. All available land has been brought under cultivation, and is in most cases assured of its water supply from one of the numerous tanks, anicuts, and channels with which the district is supplied. As regards coconut planting, I do not know of any large extents being opened. Mr. Le Mesurier has cleared and planted some land near Kotawila, and also inland on the edge of the Dediagalumukalana; but native capitalists do not seem to care about opening anything but the very best land. This is scarce everywhere and even near the coast, where there is still unplanted land: most of it is condemned as unsuitable.—*Mr. Vigors' Administration Report for 1896*.

CROPS AND FOOD SUPPLY IN THE HAMBANTOTA DISTRICT.

Though the rainfall during the year was not above the average, the crops were fair, thanks to the different irrigation works in the district. The acreage under paddy and fine grain and the yield is estimated by the Mudaliyars as below:—

	Paddy.		Fine Grain.	
	Acres.	Bushels.	Acres.	Bushels.
Magam Pattu ..	4,384	87,780	380	3,012
East Giruwa Pattu ..	2,227	11,148	1,972	6,348
West Giruwa Pattu ..	10,830	130,646	3,572	17,864
Total ..	17,441	229,574	5,824	27,224

A good supply of vegetables is usually raised in the West Giruwa pattu, such as pumpkins, cucumbers, brinjals, &c. These are planted in the chucuas in the same enclosures as fine grain, so it is not possible to form any estimate of the extent cultivated or the yield. It must, however, be considerable, for during the annual pilgrimage to Tissamaharama I noticed large quantities of vegetables, chiefly ash pumpkins, exposed for sale by the roadside between Ranna and Ambalantota. Of such vegetables there was a good supply, but coconuts, jak, breadfruit, and sweet potatoes were rather scarce owing to protracted drought.

There is an abundant supply of sea fish, which, however, is not made the most of by the local fishermen, who in their small boats are afraid to venture out to sea, and consequently the fishing grounds near the shore are overfished, and the number as well as the size of the fish caught is much below what it should be. During the north-east monsoon fishermen come in large boats from the Galle and Matara Districts. and during their stay catch large numbers of fine fish, the results of standing well out to sea and fishing water which is undisturbed by the local men.

Thanks to the large number of Mohammedans in the town of Hambantota, beef is generally to be had once or twice in the week, and the quality is very fair. At Tangalla, however, the supply is less certain, and the quality of the meat worse. Mutton is unknown, but goat meat is eaten occasionally by the better classes in the town. Fowls are scarce throughout the district, and ducks are never seen.

On the whole, the food supply during 1896 was amply sufficient for the wants of the people, and no complaints of scarcity reached me from any quarter.—*Mr. Hopkins' Administration Report for 1896*.

EXPLORATION AND CULTIVATION IN AUSTRALIA.—Winding up an article on recent exploration and loss of life on the Australian Continent, the Sydney Mail well says:—We are about celebrating the glorious reign which is the longest in our history. A feature, and not perhaps the least important, is that in the space of 60 years this vast continent has been surveyed from every one of its coasts through its remotest parts and now thanks to the bravery and the skill of thousands of pioneers, known and unknown, it is for ever dedicated to the occupation of mankind. Coolgardie lies beyond an explorer's "farthest." England receives the wool and perhaps the mutton and beef that are grown over the graves of Burke and Wills and the unmentioned resting-place of Leichhardt. We in New South Wales grow wheat where Oxley and Sturt gave no hope of human subsistence. The Australian desert has infinitely receded, but, as the fate of Wells and Jones denotes, there is a desert.

MOUNTING ENGRAVINGS.—Cut a piece of clean waste paper the same size as the engraving, and lay the engraving face downwards on a table or board, with the waste paper underneath. Now paste the back of the engraving until it is limp and saturated. The cartoon paper should then be damped with a sponge until saturated, and placed on the pasted back of the engraving. Press it down flat with a duster, put drawing pins or tacks round the edge, and leave for twenty-four hours. Trim off when dry.—*Iron Work for July*.

FOOD SUPPLY IN SOUTHERN PROVINCE.

The food supply of the people consists of rice, jak and breadfruit, coconuts, fish, yams, curry stuffs. The town population and the inhabitants of the seaboard consume Coast rice, and even in the interior local production is not sufficient for local requirements. Thus, in the large Bentota-Walallawiti korale it is estimated that two-thirds of the rice consumed was imported; in Gangaboda pattu one-quarter, in Wellaboda pattu three-quarters, while upwards of 2,000 bushels found their way to distant Unniduma. [All paying 10 per cent., while locally grown rice was free of tax.—Ed. C.O.]

Jak and Breadfruit.—These very important constituents of the food of the people were plentiful during the year.

Coconuts.—Probably the coconut industry is the most prosperous in the Province. It is steadily on the increase, but there is still a large extent of suitable land available. The supply of coconuts was abundant.

Fish.—The fishing season was a bad one, and the export to other Provinces contributed to the natural scarcity. The fishermen attribute the bad season to adverse currents prevailing along the western and southern coasts. However that may be, the poorer classes suffered somewhat from the scarcity; but dried fish brought from Mannar and Batticaloa found a ready sale and helped to supply the local deficiency. From Ambalangoda quantities of fish are sent up-country, and last year "fancy" prices were realized as the supply began to run short.

Yams.—The villager can usually command an ample supply of this vegetable, but where he earns wages on tea, citronella, and sugar estates he does not take the trouble to cultivate it. Although the extension of the tea, sugar, and citronella industry supplies the villager with a money wage, it withdraws labour from native products, and in this manner affects the supply of home-grown articles of food.

One of our Mudaliyars says:—"The villager formerly cultivated his plot of ground with yams, fine grain, and vegetables, and consumed the produce of his own paddy fields." Now he labours on another man's land, and is paid "partly in advances of rice or of paddy, while for the other necessities he goes into debt." He is, in short, being converted from a peasant proprietor into an industrialist, and as such is becoming dependent on his purchasing power to supply his wants. As the process continues he will become more and more sensitive to fluctuations in the price of food, and unless he learns thrift will be substantially nearer to want than when rupees were scarce and he supported himself on the produce of his own land.—*Mr. Wace's Administration Report for 1896.*

TEA BULKING ON ESTATES AND IN LONDON.

MR. LIPTON'S FURTHER VIEWS.

In answer, specially to the representations in the *Observer* against his circular *in re* tea bulking in London, Mr. Lipton has had the following explanation drawn up and forwarded to Mr. Leake, a copy being placed at our disposal:—
London, E.C., 1st July, 1897.

W. MARTIN LEAKE, Esq., Secretary, Ceylon Association in London, 61-62, Gracechurch Street, E.C.

Dear Sir,—I notice various comments in the Ceylon papers upon my action regarding teas which have not been bulked in London and as no mention is made of the reasons that compelled me to so act, I would like to put the matter clearly before your Association.

I have had great cause to complain of the irregularity of many parcels both of Ceylon and Indian teas and have repeatedly found damaged teas in the parcels, such damage evidently having been sustained before the teas reached London.

I have had whole blends of tea completely spoilt through a chest of this damaged tea getting into a blending of tea, which could not have been detected unless each chest had been turned out and thoroughly examined. What this means in a large business like mine, it should not be difficult for anyone to understand, involving as it would do a great deal of extra labor and time, and especially when it is considered that each of my mixes consists of 2,500 lb. of tea. To have a mix therefore spoilt as just mentioned, means a most serious loss to me.

Whenever a case arose, where there could be no doubt of the irregularity and that the damage complained of had taken place and existed before the purchase, I would claim for the loss incurred, but how was my claim met even by sellers who admitted these facts and the justness of my claim? Simply by an expression of regret and refusal to admit my claim and a curt reference that they were fully protected against any claim of this sort after delivery of the goods, under Clause 5 of the Public Sales Conditions. These conditions of sale were framed when it was the custom to bulk almost every parcel of tea in London and there was less reason therefore for exception being taken to them by either of the contracting parties, but what are the circumstances now? Instead of the former custom, there has grown up a practice which seems to have become the general rule with Ceylon importers, not to bulk anything here, but to run the risk of buyers discovering any irregularity or damage in the teas before they leave the warehouses, and should the damage or irregularity not be discovered till afterwards, to repudiate any claim that may arise as abovementioned. No doubt they are legally entitled to so act, but surely it cannot be maintained that such action is treating the purchaser fairly. So long as this method of dealing with just claims prevails with sellers, it is small wonder if a purchaser resents it and endeavours to secure some protection against serious losses arising through negligence or carelessness of others.

It will doubtless be said that the teas are inspected before sale, but under the present system it is absolutely impossible to properly inspect even a large proportion of the packages that are put on sale every week.

You can quite understand therefore my reasons for preferring teas that have been bulked in London as I can then rely upon their practical uniformity, and in the event of country damage this is discovered when the teas are turned out. Notwithstanding this I would be quite agreeable to buy teas that have not been bulked in London, provided I had some assurance that any claim for irregularity or damage, when clearly demonstrated, would receive the due consideration and attention it fairly called for instead of being practically ignored, as I am well aware that bulking in London is an expensive operation which I would gladly assist the planters in saving; and, if they wish buyers to help them to effect this saving is only reasonable that the planters, on their part, should waive Clause 5 in so far as sheltering themselves behind its terms and refusing to consider or entertain any claim, the *bona fides* of which they are thoroughly satisfied with.—Yours faithfully,
T. J. LIPTON.

It will be observed that Mr. Lipton now falls back on the risk of non-discovered damage to estate-bulked tea, and the impossibility under present rules of recovering anything against the said damage. On the other hand, in London-bulked tea, any damage is at once discovered in the bulking and the offending chest is marked accordingly. Mr. Lipton gives this as a good reason for his buyers preferring London-bulked teas; but in the last clause of his letter he offers to meet proprietors who care to have his competition for their estate-bulked teas, provided they are willing to make good any damage where such is shown, to their satisfaction, to have been sustained.

PLANTING NOTES.

LEMON-CULTURE is extending (says a home paper) very rapidly in California. This year what is said to be the largest lemon-grove in the world has been planted near Colton, in San Bernardino County. It comprises 9,000 trees on 100 acres.

CACAO CULTIVATION.—The lesson taught by the experience of Mr. Van Starrex—see his letter elsewhere—would seem to be, to leave nature alone as much as possible in regard to the growth of the cacao tree—no handling or pruning whatever, at any rate for many years.

“COFFEE PLANTING ON THE SHEVAROY HILLS”—is, the title of an interesting, not to say flattering, description of the condition and prospects of coffee estates on that range, contributed to the *Madras Mail*, see our *Tropical Agriculturist*. “No leaf disease” and “five cwt. an acre of crop” is an experience worth going a long way to note in the present day in Southern India; but the contributor must have overlooked some drawbacks,—or, if not, how is it that Shevaroy planters do not make a fortune and clear out every ten years or so?

COFFEE IN MEXICO, &c.—In San Salvador and Mexico coffee planters “are highly incensed at the low prices and do not wish to part with their coffee. In either country they have not shipped more than 25 per cent up to the present time. They are still making fully 100 per cent profit, as both countries claim that it costs them about 10 cents in silver to produce the coffee, which is 6 cents in gold in our currency, and they are still getting 12 cents. It is a pity that they are so dissatisfied with these ‘miserable’ profits, but it speaks volumes for the danger in which the article still finds itself. Even if some of the countries like Central America and Mexico hold back a part of their crop we believe that our estimate of 14,000,000 bags production for the present crop is a conservative one.”—*W. H. Crossman & Co.*

THE DECORTICATION OF RAMIE.—A communication from the Board of Trade was submitted to the Manchester Chamber of Commerce enclosing copy of a letter received by the Department from Tourcoing, respecting a new method of decortivating ramie less expensive than that now employed. A sample of the decorticated fibre was enclosed. This was stated by the inventor to have been freed from the bark by a machine capable of turning out 500 kilogrammes of cleaned fibre per day under steam power, or 40 to 50 kilogrammes when worked by hand. It was ordered that the samples and the communication from the inventor should be exhibited to any inquirers interested in the cultivation or manufacture of ramie.—*L. & C. Express*, July 9.

THE RAJAKADALUWA DISTRICT.—A coconut planter writes:—“The returns published recently of 107,000 nuts from 160 acres eight to eight and half years’ old are magnificent. Only in the North-West parts of the island, I fancy, can such quick returns be expected, though exceptional soil and exceptional planting, as at Mirigama, may secure similar results; but, surely, the estimator had no experience of the district when he provided only for three-fifths of the actual yield. That is certainly crying on the safe side! Will trees that crop so easily last as long as those which are slower in giving returns? If liberally cultivated, we should think there would be no risk—at any rate the neighbouring district can show very old, rich-bearing palms. As to the “estimate,” more than one-third of the crop was got in the last picking, shewing how the trees had improved in the year. To estimate higher a year ago could not be justified to the time.

CEYLON TEA FOR PEKIN.—It is of interest to learn that Ceylon tea is finding its way to the very capital of the Chinese Empire to be used in the British Embassy. Who could have dreamt of this when twenty or thirty years ago every drop of tea drunk in Ceylon was brought in “5 catty boxes” from China?

CACAO AND ORANGE CULTIVATION.—There is food for reflection in more than one communication in our Correspondence columns: “Potts” in the Cacao Dialogue (see page 64, July issue) discourses on the sin of cutting off suckers or any branches from the cacao tree; while the successful orange cultivator in Queensland (a man with trees bearing up to 175 dozen fruits each in a year) declares he never prunes his trees nor disturbs their roots!

A FERTILISER FOR ORCHIDS.—MM. A. Hebert and G. Truffaut have addressed a short paper to the Paris Academy of Sciences regarding the withering which attacks orchids cultivated in hothouses. They have endeavoured to trace the cause, and have experimented with the *Cattleya* species. Analysis made by them on a series of these plants in 1891, 1893, and 1897, that is, from the moment of importation to the degeneracy period, proves that at the latter moment the orchids are poor in nitrogen, potash, lime, magnesia, and phosphoric acid. The remedy they suggest is a fertiliser containing exactly these matters.—*chemist and Druggist*, July 3.

RHEA CULTIVATION.—Mr. J. Cameron, Superintendent, Mysore Government Botanical Gardens, Bangalore, has published a short but interesting memorandum on the Rhea fibre plant. (*Bœhmeria Nivea*) with an explanatory plate. Mr. Cameron has, under the direction of the Mysore Government, raised large nurseries of this plant, and every facility, in the shape of grants of plants is, we believe, given to planters, ryots and others to extend its cultivation. In favourable situations the rhea plant will to a certain extent, run wild, and a good suggestion made in the memorandum is that endeavour should be made to make it replace the aggressive and useless *lantana*.—*Pioneer*.

BENGAL OR NEPAL CARDAMOMS.—Two cases of this fruit, imported this year and marked “land carriage,” were sold at 1d. per lb. at a recent drug-sale. The “Nepal” cardamom has not been seen at the public auctions for many years. At one time considerable doubt existed as to the plant yielding it, but the matter was cleared up by Dr. King, of the Calcutta Botanic Gardens, who came to the conclusion that the “Nepal” fruits were the produce of *Amoum subulatum*, a native of the mountainous parts of India. The fruits are of a dark-brown colour, three-valved, and coarsely striated, the seeds being arranged as in the true cardamom, but much more numerous, and held together by a viscid pulp. In India this product is generally known as the greater or larger cardamom, the Bengali name being “Bara-elachi.” They are plentiful in the bazaars, and are valued at about 12r. per maund of 37½ lb. The seeds are aromatic and camphoraceous. They are employed in India as a cheap substitute for the true cardamom, and are largely used in the preparation of sweetmeats. An oil is also obtained from them of a pale-yellow colour. The fruit is an agreeable aromatic stimulant, and is applied to the eyelids to allay inflammation.—*Chemist and Druggist*, June 26th.

CACAO CULTIVATION IN CEYLON AND TRINIDAD,

We find in the Agricultural Society's Journal of this Colony, a very curious, as well as interesting return, in respect of the cacao cultivation of the island. It affords details as to the acreage, average crop, cost of production, the labour employed, total expenditure, etc. One heading baffles us as to its meaning, namely,—“Amount of importations per annum,” the answer being given in “L. S. D.”—The total result for 24 estates tabulated is thus given:—

COCOA.

The figures furnished by the Cocoa Planters show that the total amount spent in the Colony in producing 10,038 bags of cocoa is £17,025 or an average of £1 14 per bag of 165 lb.

The exports for 1895 amounted to 158,803 bags.

158,803 by £1 14 equal to £269,965.

CACAO ESTATES.	I. Total Acreage.	II. Cost of production per bag.		VI. Number of free-residents employed.	VI. Outside labour employed.	XII. Amount spent in production of Cocoa per annum.	XIII. Amount of importations per annum.

Very recently Mr. J. R. Martin showed in our columns that “cocoa” could be produced in Ceylon at about £1 10s per cwt., and that 55s was, perhaps, a high average net price to put against this. In Trinidad apparently, the cost of production is only a little over 23s per cwt.; but then the value of the produce is distinctly lower than for Ceylon cocoa. Still, the Trinidad figures surprise us, considering the comparative dearthness of its imported labour. Perhaps, the explanation is found in the richness of the soil, and the little trouble cacao gives after being fully established. Looking at the acreage and crops of each estate, we find that while several places do not yield, apparently, one cwt. per acre according to the return, yet there are others cropping up to 2½, 2.86, 3.25, 4.57 and, in one case “El Salvador,” to over 6 cwt. per acre. This is very fine: we suppose Dumbara Valley cacao fields at their best did not give more? The average yield for Trinidad is, however, not much above the 2 cwt. per acre estimated for Ceylon.

It is pointed out that we were unfair in our above comparison between the cost of cacao cultivation in Ceylon and Trinidad. For instance, Mr. J. R. Martin's estimate of £1 10s. per cwt. was f.o.b. for a crop of 2 cwt. per acre. A crop of 3 cwt. might therefore be put down at 26s. per cwt., and of 4 cwt. per acre at 23s. for cost of production. As regards net prices in London, too, Mr. Martin's 55s. per cwt. seems to more than oneinterested, to be very low, instead of high. We learn of one estate netting 60s., while a great deal of its crop sold at 75s. As to yield, the highest in Ceylon, we have yet heard of, is 7 cwt. per acre off a 21-acre field which had never been manured at any time and is still in excellent heart. To learn of an average yield for five years of an estate being 3.67 cwt. and the crop costing in Colombo only R20 (say 25s.) f.o.b., gives one a new idea of the profitable character, under suitable circumstances, of cacao cultivation in Ceylon. Still more, what will croakers say to an actual experience of an estate, not 100 miles from Kandy, giving last year 6 cwt per acre delivered in Colombo at R10 (13s.) per cwt.! After this, we shall certainly not be inclined to condole with proprietors of cacao property, but rather to congratulate them; although we may be as anxious as the most troubled of them, to see their Red (Caraccas) trees cleared of “canker,” “fungus,” or “beetle-borer” through the good offices or advice of the scientists.

In this connection we would call attention to a paper on next page by Mr. Hart of Trinidad, discussing and describing the different varieties of commercial “cacao” (*Theobroma Cacao*).

And once again, while on the subject of cultivation, we would inquire if any cacao-planters in Ceylon have experimented with artificial manures on their fields. If so, we should like much to know what their experience has been, and their opinions on the subject generally.

THE THOMPSON FIBRES COMPANY, Limited, has been formed to acquire from the British North Borneo Company the right to collect two indigenous fibres known as wild lamba, and wild or bastard Manila hemp.—*British Trade Journal*, July 1.

(a) No returns. (b) Young cultivations. (c) Includes cost of purchase.

A GEOLOGICAL SURVEY FOR CEYLON.

A recent "Madras College Magazine" had the following deliverance:—

It will perhaps surprise many of our readers to be told that a geological survey of Ceylon has never been undertaken; but such is the fact. Rich as the colony is known to be in plumbago, in iron ore and in gems, the extent of its wealth has never been scientifically ascertained. The *Ceylon Observer* in an editorial points out that the great industry in plumbago alone would more than justify Government in appointing a survey. The exports of plumbago have developed from 28,823 cwt. in 1850 to 326,754 cwt. in 1895. "But," remarks the *Observer*, "the exploiting of plumbago deposits is done entirely by the Sinhalese without any scientific guidance. No one knows how great may be the rich deposits that a geological survey might bring to light within certain untouched areas; and as the Ceylon Government draws a royalty of R5 on every ton exported, it has a most practical interest in extending the industry." Nor have the gem deposits ever been surveyed or mapped out, though they are known to be very rich in some localities. Iron ore too of an exceptionally fine quality is to be met with in abundance in the island and it is believed that, with freights so low, it would pay to carry the ore to London and Glasgow to have it smelted and manufactured. What further mineral wealth might be found in Ceylon, were a survey to be undertaken, it is impossible to say; but plainly such an undertaking has been too long delayed, and it is to be hoped that at no distant date Government will set itself with energy and determination to make amends for its long neglect.

 NOTES ON THE VARIETIES OF COMMERCIAL CACAO (THEOBROMA CACAO.)

By J. H. HART, F.L.S.

(From the Proceedings of the Agricultural Society.)

The samples of Cacao to which I wish to call attention are one and all the produce of trees known to Botanists as *Theobroma cacao*. The different forms taken on by these species are, strictly speaking, varieties only, and not species as they are sometimes locally called. For instance, the well known "Forastero", is to be described as the same species as the old "Criollo" of Trinidad; the difference between the two forms being varietal only, and not specific. There are, however, other species of *Theobroma* besides *T. cacao*, among which are *Theobroma bicolor*, *Theobroma angustifolia*, *Theobroma sylvestris* and others; but, so far as I am aware, none of these produce the Cacao bean of Commerce. *Theobroma pentagona*, a species which is doubtfully distinct from *Theobroma cacao*, produces a very fine class of commercial Cacao, and is one of those varieties introduced from Nicaragua by me in 1893. These will probably show their character within the next two years. One plant at the gardens on which I was relying for the production of pods this year, has been unfortunately killed by the beetle borer, but I have the young pods in preservative fluid for examination, which clearly shows it to be a distinct variety, if not a distinct species. Common observation shows clearly that the variation in the form and colour of the pods of *Theobroma cacao*, is wide and distinct, for we see them in all shades of red and yellow, and some have been found with a milky white exterior, when ripe, while others are nearly black. If we examine the interior of the pods, and cut through the seeds, we again find a great variation of colour, ranging from white to a deep purple, and usually with a differing flavour in proportion to the amount of colour present in bean; the white being of the mildest flavour, and the purple strongest and most bitter. Examining the samples on the table we

find that the Ceylon beans are the lightest coloured of all, and that this class of Cacao has a very mild and equable flavour. The variety called Caracas Cacao is seen to give a bolder sample than the Ceylon, is heavier, but possesses a similar though darker colour, other Venezuelan samples running it very closely. The nearest of our Trinidad samples to the Caracas type is that from San Antonia estate in the Santa Cruz valley. I have many examples of the different classes of Trinidad Cacao, some kindly selected for me by local firms, and some samples taken in European markets. From these it would appear that we have a very considerable variety among our samples, but the higher qualities are in a decided minority. The samples would appear to show that there has been little endeavour among the planters to select and grow upon scientific lines, the best and highest priced forms.

According to my observation the quality of Trinidad taken as a whole, has suffered some deterioration during the past ten years, and if the process goes on it will certainly be a matter of very serious moment for planters to face in the near future. I have no doubt that the prevailing contract system is to be held largely responsible for the existing qualities of Trinidad Cacao. The deep purple colour is certainly produced by a class of trees having greater vigour and vitality than those which produce the better and higher priced kinds; and therefore it is easy to see that the contractor who is paid according to the size of his trees, will invariably select those having the quickest growth. It has been fully proved by the importation of growing plants of Ceylon Cacao direct from that colony, that the class of Cacao there grown is nothing more than the original "Creole" or "Criollo" Cacao of Trinidad, which is probably synonymous with that kind known as the Old Red Dutch on the mainland and in Dutch Guiana. There is but little Cacao of this kind grown in Trinidad at the present day, and some even may not be aware of its existence, but I had specimens kindly sent to me some time since, which were found growing wild in the woodlands of one of our remote districts. These gave white seeds, and a bean having identical characters with those imported from Ceylon, which have now reached their fruiting stage. I would not advise, however, that planters should grow this kind, for it may well appear that there are other and different kinds which would suit much better. What I would suggest is, that planters should pay more immediate attention to the quality of the cacao they use for seed, for it is clearly apparent that the cacao tree is no exception to the general rule, viz., that the quality of our produce can be readily improved, if care is taken in selecting seed from those trees only which bear produce of the highest quality. We have as yet undertaken no experiments to prove whether the cacao tree can be successfully budded or grafted; but should it be found possible, it follows as a matter of course that to produce an even quality of Cacao, would be a very easy matter indeed, for it would simply be necessary to select and grow the exact kind we may require from grafted plants. A great deal, however, may be done by the proper selection of seed, and I show specimens which prove that we can produce (if we carefully select our seed) almost any type of Cacao which it may be found desirable to cultivate.

To secure trees of a class which will produce beans from which a first-class sample can be made, our procedure must be somewhat as follows:—

1st—Never select seed from any tree but those giving Cacao of the very finest quality.

2nd—To give a vigorous constitution, we must take our seeds only from those trees having plenty of vitality.

3rd—To secure large yields, we should select seed from trees which regularly bear large crops.

From the mixed character of the trees at present growing on our estates, and the opportunity which necessarily exist in the fields for cross fertilization, there

would probably in the first instance be much divergence from the type planted, but by duly excising all the trees of the poorest kinds, we should eventually obtain a first class strain, and once obtained, such a strain would be of the greatest possible value, for it assuredly will be suited to our soil. Probably there are few planters who would be willing to carry out the measures which are essentially necessary in a work of this kind. Some may say we have at present all we require. One answer to this should suffice, and this answer is, that what can be done with one plant can be done with another. We have seen the yield of sugar in the beet, improved beyond all expectation, and we have very promising results in our seedling cane experiments, and we see daily in European countries that all varieties of agri-horticultural produce are being improved and made more productive, and it cannot, I think, be truly shown that it is impossible to improve West Indian cultures. If we do not look out and try and improve our produce in quality and quantity, we may wake up some fine morning and find that other countries are a long way ahead, and that the Cacao of Trinidad had lost its long held prestige. It is, however, fairly confessed that such work as the raising of improved kinds of Cacao, is work which is not suited to be carried out on private establishments, and can best be done in public institutions, which are not alone dependent upon what they realize by produce. What private planter would be willing to sacrifice half the trees in a plantation, because they did not yield the exact quantity, or quality, or grow with the desired vigor? Yet this is one of the most essential of the operations which would have to be carried out, if we are to succeed in quickly raising standard types of the very highest class. Work of this kind faithfully and properly carried on, is full justification for the existence of Public Establishments such as Botanic Gardens, Experimental Stations, Farms, or Schools, outside of the direct teaching they afford. Work of the same kind is done in Europe for the agricultural classes by the professional seed grower or raiser, who is well paid by the sale of seeds of any new thing he may raise, but as there is little hope of such institutions being commenced here, owing to small area, it devolves upon public institutions to supply the want.

If Trinidad Cacao is actually declining in quality, and if it is true that owing to the prominence of the bitter flavour, manufacturers are not able to use so much of it as formerly, it is high time that such work as the improvement of the quality of our produce should be commenced. There can, I think, be no doubt whatever, even from the few samples on the table, that Trinidad should grow generally a better quality of Cacao, and obtain a far better average price for its produce. Some may say, can we do it? I answer, it can be done. How are racehorses raised? How are Zebu, Shorthorn, Devon, and other breeds of cattle raised? How are Dorkings, Game, Cochins, and other varieties of fowls produced? How are new kinds of Tomatos, Peas, Corn, Cabbage, etc., raised? If not in the same way and under exactly the same principles; and there appears no good reason why we should not have high grade Cacao and proper establishments for producing it, and not to be dependent upon the irresponsible contractor for the kind of trees we grow and the sample we send to market. Improvements as a rule do not come quickly, and many persons would probably wax impatient, but it is easy to point out that similar institutions in other lands have fully proved their value, by the improvements effected in all classes of vegetable produce, and there does not exist, in my opinion, any good reason why they should not be equally successful in Trinidad. There are, I know, many points which might properly have been touched upon in a paper of this kind, which I have been compelled to omit; but I trust that in any discussion that may follow, these omissions may be brought forward, for it is but proper that every should one add his mite for the benefit of Trinidad.

BRITISH CENTRAL AFRICA: NYASSA-TANGANYIKA PLATEAU:

CULTIVATION AND PROGRESS.

This plateau, from Karonga on Lake Nyassa to Kituta on Lake Tanganyika, is 240 miles long, the greater part of which belongs to the British South Africa Company. The Company have five stations on the road, viz., Nyala, Ikawa, Mambe, Mpanga and Fort Abercorn. At each station there is a white man and twenty native police, armed with breechloaders. The plateau is from 4,000 to 5,000 feet above the sea-level, and is healthy enough for Europeans. I am living at Mambe, having recently come here from Mpanga, eighteen miles off, where I have been since last May. There is a good garden and orchard. Bananas, lemons, guavas, oranges, strawberries, etc., all do well. The soil is fertile; anything almost will grow. All sorts of English vegetables do well, potatoes best of all. Wheat will grow well on the high ground. The London Mission grow a lot of wheat, and supply all the white people here with meal at 2½ a lb. Everyone could grow his own, but there are no mills in the country. Labour is plentiful and cheap—eight yards of calico a month. This costs about 5d a yard or less, and the men feed themselves. Their chief food is a small grain like poppy seed, called *malesi*, pumpkins and mealies. The Trans-Continental Telegraph is being pushed on as quickly as possible under Major Forbes, who is Administrator for this part under the British South Africa Company. It is a huge undertaking, from Salisbury in Mashonaland to Uganda. There is a weekly post both ways; a letter takes about two months to England, but delays often occur through the steamers on Lake Nyassa, and weather. I am glad to say we are to have horses up here soon. At present there is only one, and it has been here for over three years. I think horses ought to do well.—E. E. D.—*Natal Mercury*, June 18.

PLANTS AND THEIR HISTORY.—The first volume of an interesting work by Professor Ch. Joret on "Plants: their History, Usages, and Symbolism in the Ancient and Middle Ages," has just been published. It refers to the Oriental world, and especially to Asia and Egypt. The subject is treated from the pharmaceutical, agricultural, alimentary, and other points of view in a very curious and exhaustive manner.—*Chemist and Druggist*, July 10.

CEYLON PLANTERS AND THE OPENING OF THE ANAMALLAI HILLS, COIMBATORE, SOUTHERN INDIA.

We learn that a Syndicate made up of prominent Ceylon planters has already secured a block of 2,000 acres on the Anamallai Hills. This Syndicate includes Mr. J. N. Campbell (Chairman of the Ceylon Planters' Association), Messrs. Norman Grieve, N. Rowsell, E. Hamlin, W. A. Mooyart-Denison and D. Edwards and Dr. Renny; and our readers will recognise among these names men of high standing and great and varied experience. The land taken up has been the subject of a very favourable report; the elevation is from 3,600 to 5,200 feet; the rainfall is ample; the land itself excellent and very suitable at the lower elevation for coffee (*Arabica*) and higher up for tea. All this is very encouraging to such other planters as desire to take advantage of the offer now made by the Collector of Coimbatore to secure land from the large block of 80 square miles (51,200 acres) thrown open for selection. It is a great matter to have reliable experienced neighbours who, in this case, will no doubt pioneer the way with the products already mentioned and demonstrate how far a labour supply and means of transport can be relied on. In both respects, we feel sure that the Government of Sir Arthur Havelock will do all it possibly can to help Ceylon planters taking up and opening lands on the Anamallai Hills. The Governor of Madras knows well by experience the great advantage gained by the native population and the country generally through the introduction of British capital for the opening up of hill plantations. He has seen the results in Ceylon and has no doubt noted how comparatively little the general revenue of the Madras Presidency is benefited by the industry which has been the mainstay of the revenue and of the general prosperity of the community, in Ceylon. Then again, there never was a time, perhaps, when fresh and abiding sources of revenue are more urgently required in India than the present. Sir Arthur may feel quite certain of the approval of the supreme authorities both at Simla and in Downing Street, in adopting a policy calculated to give Madras a greater share of the prosperity which has attended the planting development of Ceylon. At first, Sir Arthur must know well that he will have to aid the planters with means of outlet—although this may be difficult just at present in view of the orders issued to him to suspend public works—and with such legitimate encouragement as can be given to ensure a due labour supply. If the Collector of Coimbatore and his subordinates have been duly impregnated with this view, the Ceylon pioneers should have a comparatively easy time; and surely, men taking up land on the Anamallais may be congratulated in continuing under the British flag as contrasted not only with those who go so far afield as Java and Sumatra; but also even with those whose property is situated in the Native State of Travancore. On the other hand, when once entered upon, cleared and planted, the Anamallai lands ought to be much more readily accessible to Ceylon planters, than are the Straits Settlements of Selangor and Perak, with their three or four days of voyaging from Colombo.

We cannot write on a matter of this kind—the development of planting enterprise in British Southern India—in anything akin to a dog-in-the-manger spirit. Nevertheless, we are by no

means blind to the possible effect on Ceylon interests when further competition for cool labour springs up. But facing the fact that large districts in the Madras Presidency are decidedly over-populated, we have no fear that when the surplus supplies are properly got at, there will not be enough coolies for both Indian and Ceylon planters, and these undoubtedly should have the preference whatever may become of planting colonies across the seas who look to India for indentured coolies.

DIMBULA VALLEY CEYLON TEA COMPANY LIMITED.

DIRECTORS' REPORT.—To be submitted to the Shareholders at the First Annual Ordinary General Meeting, to be held at the Offices of the Company, 16, Philpot Lane, London, E.C., on Thursday, the 8th day of July, 1897, at 12 noon.

The Directors have the pleasure to submit the General Balance Sheet and Profit and Loss Account for the year ending 31st March last.

The net amount at credit of Profit and Loss Account, after providing for general expenses, Directors' fees, and writing off £1,000 of the preliminary expenses, is £13,375 6s 2d.

Dividends aggregating 6 per cent. have been paid for 1896. *less* Income Tax, on the Preference Shares, amounting to .. £3,000 0 0

Interim dividends aggregating 7½ per cent. on the Ordinary Shares have been paid up to 31st December, 1896, amounting to 7,500 0 0

It is proposed to pay a final dividend of 2½ per cent. on the Ordinary Shares (making 10 per cent. in all), which will absorb 2,500 0 0

It is proposed to carry forward to next year a balance of 375 6 2

£13,375 6 2

For several months after the inception of the Company, by reason of legal difficulties in obtaining possession of some of the properties, the Directors were unable to exercise control over the working of the estates referred to. The exceptionally high rate of exchange ruling for the whole year and the loss sustained in supplying rice to the coolies, both consequent on the Indian Famine, constituted a serious deduction from this season's profits.

Notwithstanding these drawbacks, and the unforeseen expenses connected with the first year's working of a new Company, the directors have pleasure in recommending a final dividend of 2½ per cent., making 10 per cent for the year.

The Chairman visited Ceylon last winter, and reported most favourably on all the estates, and also appointed as manager Mr. C. J. Pattenson, a gentleman of great experience. The directors feel absolute confidence that the Company's interests in Ceylon are in safe hands.

The total area under full yield was ..	1,441
Mostly giving its maiden crop ..	250
Not in bearing, about ..	194
	1,885

To plant, say	25
	1,910

The total tea crop for the year was 801,629 lb., realizing the fine gross price of 9.22d. The average rate of exchange was 1s 29.10d.

Your directors having had the offer of Langdale estate, lying adjacent to the other properties of the Company, at the price of £22,000, purchased as from 1st April last, the vendors accepting in payment £12,000 in cash, and 1,800 ordinary and 200 preference shares. The purchase-price has been paid, and the shares allotted to the vendors. The conveyance having been completed, the Estate is now being worked on behalf of the Company. The

Directors consider this property a valuable acquisition. It consists of 272 acres of Tea in full bearing, and 31 acres of jungle, &c. The elevation runs from 4,200 to 4,500 feet above sea level, and its Tea-producing qualities are amongst the best in Ceylon. The crops have averaged about lb. 450 per acre, realizing from 10d to 1s, and your Directors are confident that, with the cultivation this property will now receive, crops equal to the other gardens will result. In order to meet this outlay, it is now proposed to issue to the holders of Ordinary Shares the balance of the fresh issue, viz., 1,267 Preference Shares and 1,133 Ordinary Shares. They will be offered to the Ordinary Shareholders at a premium of £1 per Share, in proportion to their present holdings, and notice will be sent with this Report.

NATAL TEA: BARROW GREEN TEAS.

Mr. John Fraser is again to the front at the Agricultural Show in Maritzburg this time as witness the following from the *Natal Witness*, May 29th:—

In our report yesterday we omitted to make more than passing reference to the excellent exhibit of teas by the Barrow Green Estate, which obtained a special and a v.h.c. The exhibit was in charge of the manager of the estate, Mr. J. Fraser, an experienced and enthusiastic planter, who though he has only been connected with the estate since February has succeeded in obtaining a grand sample of tea, this being an extraordinarily rich Golden Pekoe, of which 1 cwt. was shown. The tea in question was made in March, and without exaggeration it may be said that it will be extremely difficult to find any of better quality in the Colony, or even farther afield. So much is this particular tea sought after that 5s per lb can be readily obtained and was indeed, obtained for a 20 lb. case yesterday. The Barrow Green teas are, it is pleasing to hear, gaining popularity every day, and there is a growing demand for them both in the Transvaal and the Cape Colony. Mr. Fraser is to be congratulated on the success which has attended his efforts.

MANUFACTURES SECTION I.—FOODS, EXTRA.

(3), Barrow Green Estate tea; h c, Stantial & Allerston, lemon squash, lime juice and cordials, manufactured in 1897 by exhibitors, 12 doz.; h c, W. Francis & Son, ginger ale, soda water, manufactured by S. S. Birch & Co. in 1897, 12 doz.; h c, R. Derrett, mineral waters and ice, manufactured by exhibitor in May; h c, Hesom & Sons, Maritzburg, spiced beef; h c, Hesom & Sons, carcasses, beef and mutton; c, Barrow Green Estate, tea.

A VISIT FROM THE "SUGAR ISLAND."

WM. SCOTT, ESQ., DIRECTOR OF
FORESTS AND GARDENS,

MAURITIUS.

Sixteen years without a change, is a long spell of work to put in, in a tropical colony like Mauritius, and this has been the experience of Mr. Scott who is now on his first holiday since, in 1881, he succeeded Mr. Horne at the head of the Mauritius Gardens and Forests. Mr. Horne paid two visits to Ceylon during his term of office, once in the "sixties" to carry back a consignment of the then precious "cinchonas" granted by the Ceylon Government, and once again in the "seventies" when on furlough. He was an esteemed correspondent of the late Mr. Wm. Ferguson, F.L.S., and we have often quoted his writings. Mr. Horne, though retired on pension, cannot be idle and living in Jersey, he is giving his attention a good deal in that delightful climate to horticulture. No one would suppose that Mr. Scott, his successor, had been so

long without a change; but then he is a hard-headed as well as athletic Aberdonian, and his work as Conservator of Forests must take him a good deal over the island and into the higher districts. Still, height is comparative, the highest point in Mauritius being under 2,800 feet from which the sea can be seen breaking on the shore all round the little island, and even Bourbon, 80 miles distant, be descried. As regards forests, Mr. Scott has only about 2,500 acres of virgin forest, covering the water-shed at the highest part, under his care; but a great deal has been done by Government in planting up with Grevilleas, Blue Gums and Casuarinas. The last-mentioned is the favorite tree with the sugar-planters which they put in on abandoned land for fuel. Besides this, little but sugar is attended to. There is no chance of the little experiment in tea, leading to any extended industry; a far more likely by-product would be cacao, suiting the deep rich soil (but not the hurricanes) and requiring far less labour than sugar. A good deal, however, can be said for the Mauritius planter confining his attention to the product for which he has provided very costly buildings and machinery and which, on the whole, best suits his rich soil. The troubles in Cuba should give sugar a "spurt" at present; but the fact is that Mauritius has almost become a Dependency of India in respect both of its imports and exports—most of its finest sugar goes to India from which it gets coolies and rupees. Part of the sugar, of course, goes to Europe and also some to Australia and America direct. As to total exports, we quote as follows, the latest figures to hand:—

In 1894 the weight of sugar exported was 139,449,413 kilos., with an estimated value of R28,672,068. The value of the rum exported was R424,697; that of vanilla, R82,720; that of aloë-fibre, R171,526; and that of coconut-oil, R187,116.

On landing from the B. I. steamer last July, Mr. Scott went at once to Kandy and became the guest next day of Mr. Willis at the Peradeniya Gardens. Two days later he passed on to Nuwara Eliya and visited Mr. Nock at Hakgala. He is delighted with the hill-country of Ceylon and felt elevated, standing in Nuwara Eliya 6,200 feet above the sea (no time to do Pedro close by with its 8,296 feet) as compared with the maximum 2,711 feet of his own island. Mr. Scott left a few days after for Europe by the B. I. ss. "Golconda" and it is satisfactory to think he carried away so pleasant a recollection of his visit to Ceylon.

RAMIE (RHEA CULTIVATION.

PRACTICAL EXPERIENCE.

The article on "Ramie" (this name is more generally familiar in Jamaica than "Rhea") reproduced in your May issue contains three important statements:—

- 1.—That India generally is not so suited for Ramie cultivation as has been supposed;
- 2.—That Ramie, when grown in some places there proved quite unfit for commercial purposes;
- 3.—That Ramie cannot withstand a drought.

1. One of the chief and most important arguments put to me, why Ramie is not likely to prove commercially successful in Jamaica, is that the enormous quantity which could be produced in India would soon swamp the market, and would be put in at a figure with which we could not profitably compete. The above article confutes this statement, and points out that only a comparatively small area in India is suitable for the production of Ramie on a business

basis. It must also be borne in mind, that any advantage India may have over us in this industry, so long as the preparation of Ramie for market remains essentially a hand process, lies in her cheaper labour, and that this advantage will be greatly reduced, if not entirely swept away with the advent of a successful decorticating machine. Then, aided by machinery, or proximity to market should enable us to compete with success. I venture also to suggest, that the innumerable uses to which Ramie fibre could be put, owing to the low price at which it could be produced with the aid of a successful machine, or process; underselling cotton, Jute, Flax, &c., and being capable of replacing all these to advantage, make it improbable that the world's supply should exceed the demand, at least in this generation.

2.—The second statement:—"It was then proved that the Rhea stalk of Saharanpur was usually *quite unfit* for conversion into fibre," is perhaps the most important, shewing that, although Ramie may be grown, it may at some time prove commercially useless. How are we to ascertain whether this is the case or not with the Ramie we are growing here, without putting some through a machine or process? It is most essential that one should be able to ascertain this before entering into extended cultivation. I must admit the growth of Ramie in my rough nurseries has been very unequal; the flowering stage varies greatly, some blossoming at 2 ft. high and others not before 5 ft. and upwards; it is therefore quite possible that if cut together as a crop, some difference in the quality of fibre might be apparent. The third statement by Mr. Baden-Powell "drought kills it outright" would if correct, show that Ramie cultivation, without irrigation would be a very risky one in Jamaica. What little experience I have had here tends to show that this statement is incorrect. I cut down my Ramie here on and after 19th January last. It is admitted we had this year one of the severest droughts ever known in this district; yet by end of March last, or in about two months with drought, I cut some stalks averaging 3 ft. 9 in. and over. From 27th April to first week in May last, I had my Ramie cut down, (that is what had not already been fed down by small stock, sheep and pigs.) On 19th May, or after about three weeks' growth, I cut Ramie measuring over 4 ft. This Ramie nursery is well established; say two years old. The cuttings, planted out during end of last year, died apparently from the drought. I feel therefore justified in expressing my opinion, that Ramie, *once thoroughly established in suitable soil*, will not only withstand a severe drought, but may also grow during dry weather although less quickly than usual. Mr. Allison, a well-known American authority on Ramie, supports this view in his pamphlet, where he states, in reference to a Texan Ramie Plantation:—"But early in July, 1889, a drought began, which lasted nine weeks. During this period, so great was the intensity of the heat, that the soil was dried to a depth of more than two feet. Hundreds of thousands of coffee plants perished, but Ramie survived the drought, and, quickened by the fall rains, grew with such luxuriance, that often 150 stems were found in clusters not more than two feet in diameter, etc." The article in your *Journal* does not state what variety of Rhea is referred to. My plants are of the "Nivea" variety or white under-leaf. As my seeds came originally from Mr. Allison, I presume it is of the same variety he writes. My neighbour Mr. Craig, has, however, been growing the "tenacissima" variety, and as he has, since the drought, supplied me with growing roots, it is evident this variety can also survive a drought. Dr. Morris in his late lectures did not touch upon these points probably because he saw no future for Ramie here until a satisfactory decorticating machine, or process had been made available. It would be interesting to hear the experience of others, who are trying Ramie in this country; as to its general growth, and power of withstanding drought.

SIDNEY MOXSY,

Suttons, Chapelton, 22nd May, 1897.

WORN-OUT COFFEE LAND IN JAMAICA

PROPOSED MANURIAL EXPERIMENTS.

In my evidence before the Royal Commission, April 1st, 1897, I stated that up to that time I knew of no manure, or system of cultivation that could bring back our exhausted coffee lands to a bearing state, and that unless something was found there would be no coffee cultivation in this Parish after the next 25 or 30 years. It must be understood that my statement referred to a larger cultivation than that of the peasantry which consists of a patch round each dwelling, and which is kept in heart by penning pigs, etc., and the usual household garbage; this I call garden cultivation, as contra-distinguished from a large cultivation, and I have no doubt that such a cultivation succeeds on old worn-out land, but I am sure that it would be impossible to cultivate, say 50 acres, in this way, therefore, if coffee cultivation is to be carried on on a large scale in this Parish experiments must be made with the various fertilizers on the market. I have spent considerable sums in manurial experiments but I am sorry I am still unable to say that I have found out the right sort. Unfortunately my trial of "Berts" Coffee Manures was a failure, owing to the unfavourable seasons during the last two years. Owing to Dr. Bernard Dyer's

ANALYSIS OF MY SOILS

I began to apply lime to my coffee trees, and although it was highly disapproved of by my fellow coffee planters, seems to me to have done good. It certainly made the trees grow, although there was no crop. I applied 30 barrels per acre but as lime in this quantity is difficult to get I doubt whether this mode of fertilizing is practicable (my experiment (?) took 9,000 barrels). Mr. Bert suggested Marl as a good cheap fertilizer so I went as far as to dig, sift and put Marl in heaps of a barrel, here and there all over my fields, but when I saw how poor the crop was last year, I thought I would wait till the trees bore a crop before putting it into the soil. My idea now is to carry out a scheme of exhaustive experiments with Fertilizers, keeping a strict account of all expenditure, cultivating highly, noting the effects of the different manures, rainfalls, weather, etc., and I intend parceling out into quarter acre plots some ordinary common pasture land. My object in writing to you is, that I hope you will make my idea known to the various makers of coffee manures and if they think fit to supply me with enough to cultivate say a quarter of an acre, I assure them that their various fertilizers shall each have a fair trial and that I will supply them with all the information they may think necessary, and I shall be glad to receive any instruction as to the mode of application of their manures. I may say that I intend cultivating two quarter acre plots under any circumstances, one with applications of sifted marl and coffee pulp; and one with Bonemeal and 10 per cent of high grade Potash. The former being with the object of ascertaining whether there is any value in marl and pulper trash, (because if there is, every small cultivator in the Parish can avail himself of it) and the other, the Bonemeal one, I am trying on the advice of Mr. Robert Craig and others. It seems to me that there should be no hesitation on the part of the

MANURE MANUFACTURES

to give enough of their manures for these experiments on worn out land; because if any, or all, succeed in making coffee growing possible, *i.e.* with a margin of profit, there is an immense market open to all, as it is quite certain capital would be forthcoming to reinstate the thousands of acres of land which used to bear coffee in the days not too long ago; there would be every reason for the industry to be centred here as the land is "easy," and accessible and there are scores of old, thrown up coffee works that could be put in order for very small sums, and labour is plentiful and cheap.

I append an analysis of the soil I propose to put into cultivation made by Dr. Bernard Dyer in 1894. It was owing to his note attached to his analysis that I put lime to my coffee.

WALTER W. WYNNE,

Brokenhurst, Mandeville, 29 April, 1897.

COPY OF ANALYSIS OF SOIL I PROPOSE TO PLANT.

Silica and Silicates insoluble in concentrated acids	7.200

Nitrogen200
Phosphoric Acid Soluble in 1 per cent Solution of Citric Acid0008
Potash Soluble in ditto ditto0028

NOTE BY ANALYST.—This soil is poor in lime and would be benefited by a good application of it.

NOTE BY W.W.W.—The soil is common pasture now but was in ruin for more than 30 years till 1890.

FRUIT TREES AND COFFEE.

The following further communication from Mr. Wynne, dated 17th May, has been received:—Since writing to you on the subject of Worn-out Coffee Lands I have had the following work done upon the experimental plot:—I have weeded one and a half acres of Common Land at the cost of £1 11s 0d which was done by day labour. I lined and pegged out the land for planting, six feet by six feet, at a cost of 6s 10½d. Cutting the pegs for same (1,875) at 1½d per 100—2s 4½d. Planting bananas 12 x 12, say 406 bananas, 3s 6d. Cost of banana suckers at 4s per 100, 16s. Planting Seville Orange Trees at thirty feet apart, say twenty five trees, 2s. Carrying and applying seventeen barrels of old stable manure to the orange holes, 2s 1½d. Cost of orange trees, 3s. Cost of planting coffee 1,400 trees 12s. Cost of digging 1,875 holes 2 feet x 2 feet and 2 feet deep at 3s 4d per 100.—72s. I have given the land a top dressing of sifted marl, actually 387 barrels at a cost of £3 7s 10½d. There was also 6s spent upon a fence, a small sum as I only had to fence one end of the plot the other three sides being already built.

It will be seen by the above statement that to hoe up the ground, peg, line out, and plant for the coffee, and digging the holes, (I had the coffee holes dug now, which I consider a great advantage, as the digging will aerate the soil, and in the subsequent weeding, between now and the time for planting the coffee, the weeds can be hoed into them) has cost, with the dressing of marl, £10 6s 9d. I have estimated that the cost of my nursery of coffee seeds will amount to 10s or 12s by the time the plants are ready to put out, it being my intention to plant the plants direct and not from suckers, which is a great waste of time, say £11 for the acre and a half—or about £5 per acre if the cost of marling is left out. It may be considered that the cost of digging the holes (3s 4d per 100) is excessive, but I am convinced, by my own experience, that if big holes are dug, the plants can be established more thoroughly, and this mode is cheapest in the end. I am perfectly acquainted with the usual mode of planting and know all the evils of it,—a thrust or two with a hoe, and the hole made deeper with a crow-bar, or, more often, a hard wood stake, the coffee suckers jammed in, a stamp with the foot—and the planting is done. I have heard of even more primitive planting, viz: a hole made with a cutlass and the suckers put in. It stands to reason that planted in either of these ways the plants have but a poor chance of thriving, and I have long since given up the "Old Time" way, and now plant in *big holes*—holes two feet square and quite two feet deep. I am quite aware that this adds to the initial cost, but know that in the end it is a saving, and the field grows more regularly and the per centage of

supplies is very small. I have before me as I write the cost of trimming, pegging and planting 60 acres which was just over £30. Also cost of 22 acres £11 16s 6d: to these sums must be added the cost of coffee suckers, say 1s 6d per 100.

WALTER W. WYNNE.
—*Jamaica Agricultural Journal* for June.

DRUG REPORT.

(From the Chemist and Druggist.)

London, July 1st.

CINCHONA.—The cinchona-bark auctions held in London on June 29th were of fairly considerable extent. The offering comprised of—

	pkgs.	pkgs.
Ceylon Cinchona	3.7 of which	253 were sold
E. Indian cinchona	1845	1520
W. African cinchona	118	118
Java cinchona	76	76
S. American calisaya	135	—
" cup-æa bark	8	—

2519 1877

Throughout the auctions there was a very steady demand, almost all the agents buying a fair proportion of bark, and only a few parcels were bought in on account of the high limits placed upon them. A considerable part of the Ceylon bark, and several parcels of the East Indian, were imported between three and six years ago, and part of the Calisaya was landed in 1893. Druggists' barks were particularly well competed for. The average unit may be placed at 3d to 3½d per lb., but for some lots a full penny-unit was reached. The following figures represent the quantities of bark purchased by the principal buyers:—

Agents for the Mannheim and Amsterdam factory	Lbs.
Agents for the Frankfurt and Stuttgart factory	78,763
Do Imperial quinine-works	66,220
Do Brunswick quinine-works	62,736
Do American	60,350
Do Auerbach	57,591
Messrs. Howards & Sons	49,968
Various druggists	42,771
Agents for French factory	29,125
	18,000
Total quantity sold	462,973
Bought in or withdrawn	125,285

Total quantity offered 588,258

The following was the range of prices paid:—Ceylon cinchona: Sucirubra, natural chips 1d to 1½d; renewed ditto 2½d to 3½d; Officialis, natural chips 2½ to 3½d; renewed ditto 2½d to 3½d; natural Ledger, stem chips, 3½d per lb.

CITRONELLA OIL is held for 1s 1½d to 1s 2d per lb., on the spot, in drums or tins. For arrival 1½d per lb. c. i. f., for drums has been refused.

QUININE.—No business whatever has been reported this week. Practically all the German agents are now without quotations, though they still nominally quote a price, being unwilling to sell excepting in small quantities to special buyers.

CINNAMON CHIPS steady: ordinary coarse Ceylon 2½d; quillings 3½d per lb.

VANILLIN is said to have suddenly advanced, most of the manufacturers being temporarily unable to deliver. There has been a good inquiry for immediate shipment to America, one of the manufacturers, who was asking 3s 1d per oz. is said to have raised his quotation to 4s 6d. Others still quote 3s 6d per oz., but cannot deliver anything immediately.

JUBILEE OF THE OOTACAMUND BOTANIC GARDENS.—The Ootacamund Botanic Gardens celebrate their jubilee year. They were opened during the Governorship of the Marquis of Tweeddale, in 1847, and now cover an area of about 51 acres. The object with which the gardens were founded was to improve horticulture in the Madras Presidency; to introduce vegetable productions not indigenous to India, and to further the distribution of seeds and plants. The gardens are estimated to cost more than 21,000r. for the present year, and the expenditure is progressively increasing.—*Chemist and Druggist*, July, 10.

SALT IN AGRICULTURE.

Pending a translation of the papers we have received from Germany on the uses of salt in agriculture, and the methods by which it is denatured, it may be well to observe that the present is only a renewal of a campaign which has been waged for many years, to induce the local Government to issue salt at cost price, or at a reduction, for agricultural purposes. Our Siyane Korale correspondent, we remember, was very strong, so far back as the "eighties," in urging the importance of salt as a manure for coconuts, in inland districts, especially those far removed from the influence of salt-laden breezes; and several past volumes of our *Tropical Agriculturist* bear evidence of his pertinacity and industry in pressing the matter on official and general attention. We were not aware, however, that the agitation then begun had been continued within the past three years; or, when we drew attention to the information brought back from Europe by the Hon. P. Coomaraswamy, that Government had been applied to so recently as March 1895 to sanction experiments with salt at cost price in coconut cultivation. But "F.B.," whose letter on the uses of "coconut husk and husk-ash as a manure" we give elsewhere, sends us, as promised, some important correspondence with the Colonial Secretary which has not been previously published, and from which we are able to judge of the attitude of our last Governor. During the administration of Sir Arthur Gordon, some attempts were made to move the Government to issue salt at reasonable rates for agricultural experiments; but the early years of his administration were so beset with financial troubles—our revenues having run down by about one-third within a decade—that Sir Arthur hesitated to touch any branch of revenue. It was pretty well known that he was favourable to Auditor-General Ravenscroft's proposal to do away with the present system of Arrack Rents; but the Government Agents had only to suggest that any change would result in a diminished revenue from arrack, at least for a time; and the Governor had immediately to let the matter drop! So, with any request at that time, that salt should be issued at a low rate for agricultural experiments—the suggestion that it might tell on the salt revenue was sufficient to ensure a refusal.

A Veyangoda coconut estate proprietor, however, anticipated a more liberal policy when all anxiety regarding the revenue was at an end; and Sir Arthur Havelock had not the same excuse in 1895 as his predecessor had in 1887 for giving anxious attention to the immediate present, and refusing to hazard a rupee of revenue. But it is so seldom that officialdom in Crown Colonies can take a large and liberal view of things, or adopt a new line on any matter which has previously come up for consideration and been adjudicated upon. An illustration will be found in our Correspondence column, in the reply which "F.B." received to his modest and very reasonable application to the Government of Sir Arthur Havelock. In reference to this answer our correspondent writes to us:—

"I was more struck with the courtesy and the considerateness of tone, of the reply, than with its force or logic. My application was not, as the first paragraph might imply, for a gift of the salt. I offered to pay the cost price of the salt, or the price at which it is sold for exportation. As you are aware, salt cost the Government about 40 cents a

cwt., and it sells it to dealers at R2/36; but it sells salt for export at R4/25 per ton, or 21 cents per cwt.!" So there was nothing unreasonable in the application. I admitted that the experiment was not undertaken from wholly disinterested motives; but it would cost me some money. I therefore wrote, 'I do not ask for a free issue of the salt, though if it were offered I should not decline it, as I shall have to incur some expense in connection with the experiments.'

"The reasons for the refusal set forth in the 2nd paragraph are transparently inconclusive. I offered to carry on the experiments, if necessary, on lines suggested by the Government, or under the direction of the Superintendent of the School of Agriculture; and nobody would expect the Government to issue salt to anyone and everyone who applied for it. It would be a sufficient answer to say, an experiment is being carried on and we are awaiting results; or, better still, salt might have been issued for experiments to half-a-dozen typical estates—typical of soil and climatic conditions, and typical of our different products; and then a more comprehensive and conclusive answer would have been available to charges of favouritism.

"The suggestion that a cooly, who would not use the salt himself, would pollute his hands with washing it clean, and would run the risks of an illicit sale—all for a few cents, as sodium chloride, though indispensable to human life has not yet reached the value of gold dust or uncut gems!—the suggestion, I say, is not one demanding serious refutation. Yet, I anticipated it, for I reasoned, on the assumption that the revenue would be defrauded to some extent, that the total loss would not be comparable to the gain to the revenue if the application of salt really benefited the soil and made it more productive. What would a few illicit sales here and there be, in comparison with the benefit to the people and the Government by the increase of crops even by one-twentieth, and by the protection of herds against the diseases which carry them away in such numbers?"

We are only surprised that the matter was not carried farther in 1895. Had the Correspondence been sent to us, we should have condemned the extremely illiberal and impolitic attitude of the government of Sir Arthur Havelock. We cannot believe that our present Ruler will content himself with following the precedent of 1895 or even ten and thirty years earlier. In the *Gazette* of May 1869 we find recorded a number of unsuccessful experiments made by Mr. Russell, Government Agent, Northern Province, under the direction of Dr. Charsley, P.C.M.O., to denaturalize salt, chiefly by the admixture of carbolic acid. Equally unsatisfactory were similar experiments by Mr. Macready—(son of the great tragedian, the "Willie" of Browning's well-known verses)—when Assistant Agent at Puttalam. But it was rather absurd to quote the failures of 1869, or the refusal—probably to Mr. David Wilson—of 1887, as precedents for Government in 1895. However, we are now likely to be equipped for the campaign in an altogether different way, thanks to the courtesy of Mr. Coomaraswamy and his friend Mr. Lange; and with the German law and practice before it, we do not think Sir West Ridgeway's Government will need much persuasion, to allow a trial at least to be made. Meantime, it is of value to have the Correspondence of 1895 placed before the public. We should also reprint the Reports of the Experiments of 1869 had they any practical value now; but we take it they are altogether too primitive in the light of the latest chemical science on the subject.

* What—at half the cost of manufacture—a dead loss?—Ed. *T.A.*

THE PLANTING OF RUBBER :
DR. MORRIS ON THE ADVERSE SIDE.

Some little time ago, we gave advice to local planters in search of a new product for which the demand seemed likely to increase as years rolled on, out of proportion to the supply, to cultivate rubber, the Para variety for choice. We cannot help still thinking that, large as is the supply of the raw product from the forests of West Africa and South America, an extending demand will do more than take it all off and that the cultivated article should meet with a remunerative market. But we are bound to show the argument on the other side, especially when stated by so good an authority as Dr. Morris. We therefore give a recent strong utterance of his on the subject, as well as other extracts referring to activity in Bolivia, Brazil, etc., and we ask our planting readers to give all that is stated, due consideration. There is just one remark we would make on Dr. Morris's mention of cinchona, namely, that there is no risk of any planting community rushing into "rubber" as the Ceylon planters did, twenty years ago, into "cinchona." Rubber is not so readily grown, or at any rate not so soon and easily cropped as cinchona bark—a very material difference which must weigh with intending planters. On the other hand, rubber is a product which, if added to an existing tea or coffee or cacao plantation, gives very little trouble after being planted along roads, boundaries, or in fields by itself, till the cropping time arrives—so that the total expenditure upon it should be very moderate indeed.

Evidently recent words of warning as to abundant supplies of rubber must have told on the British capitalist; for a scheme which opened with a glowing prospectus of a "British India Rubber and Exploration Company, Limited," £200,000 capital, to acquire and develop 500 square miles of rubber-growing country, 35 miles North of Cape Coast Castle, has fallen to the ground. The shares were not subscribed for, and yet the Reports of experts pointed to profits of something like 30 to 50 per cent. Here are a few striking paragraphs from the prospectus:—

"According to Her Majesty's Foreign Office Reports, the consumption of india-rubber by six countries now exceeds one hundred million pounds (lb.) per annum, worth in the market about ten million pounds sterling (£10,000,000); within the past 18 months the price of Rubber has risen enormously, as it is absolutely indispensable for cycle tyres, motor cars, cabs, and various other industries. It is a well-known fact that the consumption of Rubber in the manufacture of cycle tyres alone has reached prodigious proportions; and according to many competent authorities the supply of the raw material does not equal the demand. It is estimated that there are in England over one thousand cycle factories today, working at full pressure, and last year there were registered in London alone cycle and motor corporations giving a total capital of £19,898,000. Messrs. Bagot and Anderson estimate that there are at least four hundred and fifty thousand (450,000) trees yielding Rubber on the property proposed to be acquired by this Company, and the Directors contemplate making arrangements to plant a large number of additional trees, thereby providing for a future continuous supply. A very large proportion of the Rubber, at present being shipped from West Africa, is taken from the district in which this property is located.

"As it is estimated that there are some 450,000 trees on the property at present bearing Rubber, and as an average rubber tree yields a minimum supply of three pounds of India-rubber annually, which, at the very low estimate of 2s per lb. (and marketable Rubber is now selling at about 3s 6d per lb.), a gross Re-

venue should be earned from India-rubber for the first year of the Company's operations of £135,000 (*vide* report of George Bagot). The supply from an India-rubber tree is stated to increase 1 lb. per tree per annum for several years after the first year's tapping. Consequently, from the 450,000 trees, the Revenue for 1898 should be about £180,000 gross, again assuming that Rubber realises only 2s per lb. on the market in 1898. Marketable Rubber is now selling on an average at about 3s to 3s 6d per lb., so that in quoting 2s per lb. the Directors are placing a very low estimate on the sale price. It is the general opinion that the price will still further advance, and the press quotations given hereafter confirm this belief."

There can be little doubt that West Africa rivals the valley of the Amazon as a home for rubber; but year by year, the goose that yields the golden harvest is being used up and if the demand as seems likely, goes on increasing, we do not see that planters should be discouraged from putting in rubber, more especially as a by-product where they have plantations already formed of tea, coffee, or cacao, or even coconuts, as their staple.

COCONUT CROPS IN RAJAKADALUWA,
CEYLON.

(From a Correspondent.)

I was amused at the criticism the remark about crop of nuts evoked. The reference to Kandangomuwa was, of course, not made with a view of instituting an invidious comparison between it and the Rajakadalawa place; but, as you pointed out, the interest was the age at which coconut palms properly cared for come into bearing in the two districts of which these estates are typical. As to the inaccuracy of the estimate being the result of the estimator's "want of experience of the district" I would propound the following question to the "planter" critic who I assume has some experience of the coconut districts in the N.-W. Province:—guess the average number of trees from which a crop of 108,372 nuts was picked in the year on a plantation 8 to 8½ years in the Rajakadalawa district?

108,372 nuts were harvested for the 6 pickings in the year of which number as much as 63,492 were got in the last two gatherings (March-April and May-June.) The estimate was originally 65,000 (since raised to 95,000); but the forecast was made more than a twelve-month ago and the number of trees that came into bearing immediately afterwards was larger than was calculated upon, while the crop bearing capabilities of the palms which were then already in bearing also proved to be better than what was expected. Those who have had any experience in the matter know that an estimate of crop for a young coconut plantation *just coming into bearing* is at best mere guesswork. There are no data to go upon. To begin with, in making an estimate for the following twelve-month, the number of trees that will be in bearing within the next 3 months has to be guessed and when the palms are not uniform, this is not an easy matter.

MICA BOILER COVERINGS.

The increased use of electric power during recent years has led to a largely increased demand for mica for insulating purposes. But the producers of mica have not found in the electric demand any relief from the state of affairs which was a continual source of loss to them before it began. Large sizes and good shapes of mica, such as are required for insulation purposes, were always marketable, but the difficulty remained of disposing of the waste or scrap which forms so large a percentage of the output of mica mines and accumulates so rapidly at mica-cutting works. Through the initiative of Mr. H. C. Mitchell of Toronto, this waste mica has now a value though no doubt a small one as

compared with the merchantable sizes. It is being utilised as material from which to manufacture coverings for boilers and steam pipes to lessen the loss of heat by radiation, mica being a good non-conductor of heat as well as of electricity. The scrap mica blocks are first put through a series of corrugating rolls which loosen the laminae; these are finally separated from each other by air currents, after which the sheets are again put through a process which corrugates them singly. They are then laid between light galvanised wire-netting, made into webs of a thickness suitable for the particular purpose they are intended to serve, and stitched with wire on a machine the first of its kind yet made. The flexible web of mica is covered with canvas stiffened at the back with millboard, and rounded into the desired shape. The covering when finished is fastened on the pipes by firmly lacing the edges together.—*Indian Planters' Gazette.*

THE ANGLO-CYLON AND GENERAL ESTATES CO., LTD.

DIRECTORS:—Quintin Hogg, Chairman; Claude E. S. Bishop, Norman William Grievce, Alex. William Crichton, Managing Director; and Henry Kerr Rutherford.

Report of the Board of Directors to be presented to the stockholders at the eleventh annual ordinary general meeting, to be held at 20, Eastcheap, London, E. C., on Tuesday, July 20th, 1897, at noon.

The Directors herewith submit to stockholders their report of proceedings, together with the accompanying accounts for the 11th year of the working of the Company.

The net profit as shown in the audited accounts annexed hereto amounts to £15, 15s 19d, and the directors recommended the payment of a dividend at the rate of 5½ per cent per annum on the Consolidated Stock of the Company. The dividend now recommended as above, will, if assented to by the meeting, be payable on the 3rd August 1897, at the London Office of the Company's Bankers.

In the autumn of 1896 the Committee of shareholders referred to in the last report of the directors, after making considerable enquiry and conferring with the directors of the Company, formulated a scheme for the reduction of capital, and re-arrangement of the shares of the Company. The scheme was duly laid before and unanimously adopted by full meetings of shareholders in December, 1896 and January 1897, and in due course it received the necessary sanction of the High Court.

The effect of the above changes was to reduce the capital of the Company to £250,000 Consolidated Stock, of which the old preferred shareholders were allotted £204,510, and the old ordinary shareholders £45,490, while the preferred shareholders received the dividends in arrear partly in cash, and partly in surplus certificates payable as therein specified.

New certificates have been duly prepared and are being issued in exchange for the old share warrants to bearer, as and when surrendered.

The name of the Company was also, pursuant to resolutions, adopted at the above meetings, changed from The Oriental Estates Company, Limited, to The Anglo-Ceylon and General Estates Company, Limited, and this change was officially sanctioned on the 26th April 1897.

In further pursuance of the policy already approved by shareholders, and referred to in the last Report of the Board, the directors have satisfaction in stating that the liquidation of the Highlands Company of Mauritius, which had been occupying their attention for some time, has made considerable progress during the past twelve months. A large area has been disposed of in lots to native cultivators and others, and there is good reason to hope that the remaining lands will gradually be taken up in a similar manner. The factory on this estate, which is a powerful one, and capable of dealing with a

large crop, will, together with about 500 acres of selected cane land, be retained by this Company, and worked as a Central factory.

The quantity of sugar from the Mauritius Estates, amounted to 11,960 tons as against 12,066 tons in the previous year, the canes being reaped from a smaller area.

The tea crop in Ceylon during the period under review amounted to 1,743,824 lb., which includes 21,406 lb. from bought leaf, as against a total of 1,649,577 lb. in the previous year. The gross average price was 7.95 pence per lb. in London.

The cocoa crop was 1,346 cwt as against 1,390 cwt. in the previous year, and the price realised was 60.8 per cwt.

With the consent of the Trustees for the De-benture holders the outlying estate of Havilland in Ceylon, was sold as from the 1st January of the present year.

The results of the working of the estates in Ceylon and Mauritius respectively are given in the profit and loss account, calculated at the average rate of exchange of 1/2½, as against 1/1½ in the year 1895-6.

The directors have pleasure in expressing their satisfaction with the manner in which their representatives, both in Mauritius and Ceylon, have performed their duties under circumstances of considerable anxiety.

Mr. C. E. S. Bishop, a member of the Shareholder's Committee above mentioned, was on the 18th February last elected to a seat on the Board of the Company.

Many large shareholders have expressed a desire that Mr. S. C. Macaskie, the Chairman of the Shareholders' Committee, should join the Board, and a motion to that effect will be submitted to the meeting, and, if it is carried, the necessary alterations in the articles of Association will be laid before the extraordinary meeting of which notice is endorsed hereon.

In accordance with the articles of Association, Mr. Henry Kerr Rutherford retires from the Board, and, being eligible, offers himself for re-election.

The Auditors, Messrs. Welton, Jones & Co., also retire from office, and have expressed their readiness to act if re-elected.—By order of the Board,

HENRY GREEX, Secretary.

7th July, 1897.

DIMBULA VALLEY CEYLON TEA CO.

THE CHAIRMAN'S SPEECH.

Gentlemen,—In moving the adoption of this, our first annual report and accounts, which has been circulated amongst the shareholders, and has appeared in many of the public prints, I think I may safely congratulate you on your year's working, especially when all the circumstances and difficulties connected with our first off-go are taken into account. First we experienced difficulty in getting possession of two of the properties; secondly, we had an abnormal

high rate of Exchange, which ruled, I may say, from the date of drawing our first bill of Exchange; and then there was the scarcity of rice and of labour. I think, therefore, that it must be satisfactory to you to find that, notwithstanding these drawbacks, a substantial dividend is possible. We are now in quiet possession of the estates, which since January last have been managed by Mr. C. J. Pattenson, who resides on one of the properties, and gives practically his undivided attention to the Company's interests. I was fortunate in securing the services of this gentleman when I was in Ceylon last December. He is well known to most of your Directors, and I feel sure the Company's management there is in safe hands. During the first months Mr. Thomas Mackie acted, until we could appoint a permanent manager. Mr. Mackie is a gentleman of great experience, and was of infinite use in organising the Company's staff, and taking over the estates from the vendors. As I have stated, we are now in full working order. Exchange is more in our favour, and rice will soon be obtainable at lower prices, owing to a satisfactory monsoon. Labour, too, has been coming in more plentifully lately, hence most of our difficulties of last year are rapidly disappearing. To some, no doubt, it may appear lacking in caution to have commenced with so large a dividend as 10 per cent., instead of carrying forward a larger balance than we have done, but, deliberating on this point, your Directors had in view the gradual increase in crops, which will enable them not only to continue to pay similar dividends, but to gradually build up a substantial reserve. Ten per cent. is not so large a dividend as one or two of the lately-formed Companies pay, but in estimating the satisfactory character, or otherwise, of this, I would ask you to bear in mind the source from which your dividend is derived. Every acre you possess is of first-class soil. The estates are situated in perhaps the best district of Ceylon, at an elevation of from 4,000 to 5,000 feet, producing teas of a high class, as our prices for the year indicate. I consider the Dimbula Valley Tea Estates are amongst those holding a unique position in respect of the bugbear over-production, which some discern in the horizon, but, even if there is reality in that in the case of common teas, I think our's may have immunity. The area over which teas such as our's are used almost entirely for blending and for bringing up to a certain standard commoner teas, is very circumscribed. Indeed, it is practically already planted up, so that no extension of cultivation can take place. In fact, many people whose opinions are worth having, say that the more common teas there are produced, the more will be the demand for our's. Be that as it may, you have embarked in a concern which will hold its own in stability and ability to pay dividends. This year, in spite of our difficulties, we have a net of over 4d per lb., and, provided we get similar prices during the current year, the net for our teas will be nearer 4½d or 5d, and it is not difficult to calculate what a half-penny more on a million lb. of tea means. We have now a fairly good supply of labour on our estates, namely, 1,742 coolies, and, although our advance of 20 rupees per head is very much less than many estates, I hope to see some reduction during the current year. Langdale estate, which is in the same district as our other gardens, was offered to us at a price at which your Directors deemed it advisable to secure it. It is a property which yields similar tea to our other gardens, and is of first-class soil. The price paid was actually £21,000, half in cash and half in shares at £1 premium. Deducting the premium on 2,000 shares, the estate will stand in our books at £2,200, and should, judging from past figures, yield 12 per cent., should we only get similar crops. But the Directors are hopeful that, with the cultivation it will now receive, and the economy in being worked with the whole group, even better results will be obtained. The balance of this issue to meet the £12,000 cash paid to the vendor has been allotted pro rata to ordinary shareholders at £1 premium, and has all been taken up. I have pleasure in moving the adoption of the report and accounts.

PLANTING PROGRESS IN PERAK, STRAITS.

FROM ANNUAL REPORT ON THE MATANG DISTRICT FOR THE YEAR 1896.

ESTATES IN MATANG.—There are three coffee estates in the Matang district, viz:—The Jebong estate, with Mr. F. A. Stephens as owner and manager. The estate of the Straits Coffee Planting Company, under the management of Mr. Mac Gilvary. On the Jebong estate 165 acres have been planted. The young coffee on this estate seems to be doing remarkably well. Mr. Mac Gilvary has opened and planted about 80 acres. Both these estates are situated in low lying land, entirely different in every respect from the estates opened up at Waterloo, Gapis, Rumah Papan and Kamuning. The land appears very rich, and the managers sanguine as to results, which I sincerely hope will be more than justified. Mr. C. L. Gibson owns the other coffee estates, but he has so far only cleared a small portion and put in his nurseries. Tapioca has been planted by a Chinaman named Goh Hooi Chew to the extent of 692 acres. He has also planted 300 acres of coconuts, and has 8,000 more nuts ready for planting. There are about 20 acres of pepper in the district, the balance of the 80 acres granted to Haji Yusuf. Sugar has not been planted as yet, although the Stewart and Kennedy concession should have been commenced some time ago. This causes a great deal of trouble to the *padi* planters in the vicinity, owing to its jungle affording shelter to the pigs and vermin which destroy the *padi* all round.

PLANTING IN SELANGOR, STRAITS. REPORT ON THE KUALA LANGAT DISTRICT FOR THE YEAR 1896.

LAND AND AGRICULTURE: EUROPEAN ESTATES.

The year has not been successful as regards European enterprise. Messrs. Maynard and Rendle were allowed to abandon the greater part of their block and are now taking up 300 acres of fresh land in its place. Similarly, Mr. Borring found himself compelled to abandon his coffee planted alongside the road (amounting to several acres), though I am glad to say that some fifty or sixty acres at the back of his estate near the river bank appear to be really good, and are growing what is generally admitted to be some of the finest coffee in the State. At the end of the year Mr. Borring applied for, and obtained, about 120 acres of good land adjacent to his estate. Mr. Orchard, who had purchased a block (No. 51) on the Klang Road, was permitted to exchange his land for a block of similar area in Klang district. Finally, Mr. Bernard, who was granted 1,000 acres of land near the eighth mile on the Klang road, abandoned his land entirely, and has, I hear, taken up land in Sumatra. The main cause of this want of success was no doubt insufficient prospecting. There is an abundance of really first-rate land at Telok, as in other parts of the district, but it requires more careful prospecting than it has had hitherto. On the other hand, signs are not wanting that low-water mark has been passed, and, with a fresh start and better luck, I am confident that a really bright future will be in store for this hitherto backward part of the State. Thus, at the time of writing, I have just received a letter applying for a thousand acres of land on the Klang Road, where the soil is known to be excellent, and where the 18-foot road, when gravelled (as it should be next year), will materially assist the development of this part of the district, whilst yet other land in the same neighbourhood is being prospected by applicants who desire large areas.

CUSTOMARY HOLDINGS.

The total area of customary holdings on the mukim registers for 1896 was 6,255 acres 1 rood 33 poles. The total area of land applied for was 2,195 acres 2 roods 11 poles. The total area of land demarcated, 1,636 acres 3 roods 22 poles. The total area of land issued under extracts from register during the year was 546 acres 1 rood 39 poles.

There were 32 mutations of customary lands during the year. An area of 1,051 acres 2 roods 13 poles was demarcated at Klanang, but it was not possible to prepare the extracts and to bring them on the rent-roll before the end of the year; there will, however, be an exceptionally large addition to the rent-roll in 1897. To enable land work in this district to be brought up to date and in accordance with the new instructions issued a special clerk for land work is required. The new settlers at Klanang are almost exclusively Javanese, who form our best colonists, and are still the pioneers of planting in localities yet unprospected by Europeans.

PROGRESS OF CULTIVATION.

COFFEE.—Coffee is still the rage among native settlers, and during the year the whole of the roadside as far as Morib, nearly ten miles, has with a few unimportant gaps been taken up for the prevailing coffee-culture, which is rapidly converting this part of the district into one vast garden.

It is an especially healthy sign that many of the proprietors of bright green patches of lalang by the roadside have at length awoke to the fact that their property has a value, and have commenced to cultivate it. The demand for land has been growing perceptibly brisker for some time past, and an acre of coffee at Klanang now realises something not very far short of Klang prices.

In October I received on a single day 38 applications from Chinese for land at Tanjong Duablas, whilst in December I received also on a single day 44 applications from Malays for land at Telok Gongjeng, a portion of the big island opposite Jugra, which has hitherto been occupied solely by Sakeis.

As an example of the universal coffee-fever, I may remark that near Sepang there is a small plot of ground which some Sakeis have started to plant, and on which they have built the small thatched hamlet in which they reside.

PEPPER AND GAMBIEB.—Cultivation of both these products has been practically at a standstill on the Sepang estates owing to the prolonged absence of the manager, to which reference has already been made. Neither pepper nor gambier is a species of cultivation which it would be wise to encourage in future without making some stipulation as to the planting of shade-trees.

COCONUTS.—The area taken up for this form of cultivation has not increased during the year, though there is no reason why it should not do so, the soil near Morib being especially well adapted to this form of cultivation. Some of the best coconuts I have seen in the State are to be found close to the sandy beach at Morib, and there must be at least 30 or 40 miles of sandy coast in the district on which they would flourish exceedingly.

REPORT ON ULU LANGAT DISTRICT, STRAITS, FOR THE YEAR 1896.

LAND AND AGRICULTURE.—A great demand has sprung up for agricultural land in the Kajang mukim due, to a great extent, to the advent of the railway, which has also had a marked effect on the value of town lands, vacant building lots having risen 100 and 150 per cent. in value during the past twelve months. About 80 per cent. of the customary land applied for during the year has been selected for the purpose of Liberian-coffee cultivation and practically nothing else in the shape of permanent crops is receiving attention in any part of the district. Further impetus has been given to this form of agriculture by the influx of more European capital, six blocks of 320 acres each having been alienated to European planters during the earlier part of the year. The total area under cultivation on all estates under European management amounted, at the close of the year, to about 1,200 acres.

WILD ANIMALS IN SELANGOR.

Mr. Walter D. Scott, Acting District Officer, Kuala Selangor, reports:—One tiger, four panthers and 180 crocodiles were killed during the year, the rewards for which amounted to \$256.25

REPORT ON ULU SELANGOR DISTRICT, STRAITS, FOR THE YEAR 1896.

LAND AND AGRICULTURE.—3,925 acres of customary lands were given out as compared with 1,644 in 1895. The average price at which customary lands changed hands was \$25.58 an acre. The average price in 1895 was \$18.27, and this increase is I think one of the most satisfactory signs of progress and prosperity I have to record. At present there are only two estates, both of 320 acres, held under title. Three more of a like area are in process of alienation. Of the two held under title one, at Batang Kali, belongs to Messrs. W. Meikle and H. A. Hamerton, and was originally taken up in 1894. A considerable portion of this estate is now planted with coffee. The other, held under permit by Mr. J. Pasqual, is now fully planted up with coffee. Four other blocks, extending to an area of 460 acres, have been applied for, but pending survey it has not been found possible to issue titles for them. Nearly all the lands opened during the year have been planted with coffee. I am agreeably surprised to note how clean and clear of weeds the large majority of native coffee gardens are. It would probably be a great benefit to cultivators and Government alike were there an officer available who had a good knowledge of coffee cultivation, and who could be spared to go round all the native holdings and give advice. I find that most of the cultivators are only too anxious to be instructed. One hears a good deal against the native practice of planting padi and other auxiliary crops amongst their coffee during the first year or two, and it is occasionally recommended that this should be altogether prohibited, but to prohibit it is to prohibit a number of new settlers planting coffee at all, as there are very few native immigrants who came to the country with sufficient capital to live on until their coffee plantations come into bearing. Under instructions from the Government I held a meeting, on 6th June, of all the penghulus in the district to discuss what could be done to encourage and increase the cultivation of padi. They all seemed very anxious to see more padi planted and suggested many irrigation schemes with this object. I have no doubt that the cultivation of padi could be very largely increased, but the Government must be prepared to allow (1) a considerable sum for irrigation works, (2) security against disturbance by miners, and (3) a sufficient land office staff to supervise operations.

BRITISH CENTRAL AFRICA COFFEE.

We have received from Mr. Duncan (of Messrs. H. J. Gardiner & Co.) some statistics of the past season's coffee crop. The best price ever obtained for B. C. A. coffee was in the past year, viz., 11s 6d, obtained by the firm of Buchanan Brothers for several parcels of peaberry. The average price of the whole crop assigned to Messrs. Gardiner & Co., was £86 6 8. The highest average price got by any one shipper was obtained by Mrs. A. Waller, viz., £97 6 8. On the whole, Mr. Duncan considers that this year's figures are distinctly good when compared with the results from other countries.

Mr. Duncan states that they are looking forward to a large crop this year, and if it is despatched early enough to reach London in time to be sold in October, it should again fetch splendid prices.—*B. C. A. Gazette*. June 15.

TEA PICKERS IN FORMOSA.

Between April and August tea picking constitutes one of the sights in Taihoku (Taipei). Just as in the interior of Japan, the tea pickers are girls and women, all of the lower classes. Generally girls constitute six-tenths, married women three-tenths, and unmarried women and children one-tenth. In one respect the Formosan tea-pickers surpass their sisters in Japan proper. In every tea district in the interior whether in Shizuoka and Uji, or in Yokohama and Kobe, the tea pickers are not remarkably careful

about decency. Such is not the case in Formosa, in consequence of the long established social restraints concerning manners and customs of women. The Formosan tea-pickers are neatly dressed, often in full toilette, while old and young generally fasten in their hair sprays of fragrant flowers. Therefore when one visits a tea plantation in the season he will inhale an atmosphere deliciously scented from the leaves and the head adornments. The Formosan mothers are also more considerate about their babies. They do not go about working with their little children fastened on their backs, as their Japanese-born sisters generally do both to the inconvenience of mothers and babies. When they happen to come to work with their babies, the latter are quietly placed in large beds made of bamboo provided for the purpose by the tea planters, before the mothers go to work. Thus may be seen even as many as twenty or thirty babies in one bed. The Formosan tea manufacturers do not feel any inconvenience at all in the matter of the supply of hands. There is an abundance of labour in Taipei and its vicinity for the purpose, and the people flock to tea plantations as soon as the season commences. The process is simple, girls or women employed the previous season resort to their old plantations and bring with them new recruits. No advance is asked for or paid, and as their wages are paid every day after the work is over, pickers are perfectly free to continue or discontinue work. The number of tea-pickers in Taipei, or more strictly Daitotei (Twatutia), alone is something enormous. There are a hundred and sixty tea manufacturers in Daitotei, large and small, a large firm employing more than two hundred and fifty and a smaller one about forty. Putting the average at eighty, the total number of hands for the whole of the tea manufacturers amounts to 12,800. Pickers are generally divided into three or four classes, according to their skill, and wages are paid accordingly. The 1st class pickers receive 40 *sen* a day, the 2nd class 25 *sen*, and the 3rd class 10 to 15 *sen*. But wages are also paid by results of work, at the rate of 30 *mon* (1 *mon* corresponds to 1 *rin*) per *kin*, or 5 *mon* per basket, according to plantations. It is not difficult to pick 10 to 14 *kin* or 60 baskets, a day, working from about 7 a.m. to 5 p.m. Of course no particular training is needed; a month's picking will make a girl a first class picker, provided she is endowed with ordinary intelligence. Therefore little girls of fifteen or sixteen years old, whose hands and eyes are quickest, get in general the highest pay; next, women in their "twenties," and lastly old women or children. When these have picked a sufficient quantity they deliver the leaves to overseers, who give them in exchange bamboo checks or tally-sticks, one per *kin*, and after the day's work is over the checks are exchanged for cash. Supposing that a tea-picker gets on an average 20 *sen* a day, an estimate that is most likely below the mark, the wages paid in Twatutia alone to 12,800 girls and women aggregate 76,800 *yen* a month. These are the good features of tea-picking labour, but unfortunately there is also a bad side, that is to say, corrupt morals of tea-pickers. For at least a third of the total are little better than strumpets or unlicensed prostitutes. The peculiar circumstances of life on tea plantations are the main cause of this moral corruption; the tea industry gives employment not only to girls and women but also to a large number of men. Therefore when the season begins, the ingress of labourers to Taihoku is considerable. Every junk or steamer brings to Formosa hundreds of these labourers from the opposite coast of China. In Taihoku alone at least three thousand labourers, mostly from Amoy and Swatow, arrive each season. They are men of low class, whose only desire in coming over to the Formosa tea plantations is to earn a little money and gratify their animal passions at opium shops and brothels. Under the circumstances, it is not unnatural for ignorant girls, eager to get fine clothes and knick-knacks, to be seduced into secret prostitution, for procurers are plentiful in Formosa as in any other part of the world. Indeed it is a common thing in Formosa for girls of low class to sell their

virtue for money, not unfrequently with the encouragement of their parents. Married women are also guilty of the same offence, though proportionally less as compared with the others.—*Japan Times*, July 2.

JAPAN TEA CROP.

Owing to several unfavourable circumstances which we have noted from time to time, it was generally believed that the total output of tea this year would be far smaller than in ordinary years. The latest return shows that the total amount of tea sold in Yokohama before the third instant, is estimated at 1,396,150 cattie, showing a slight decrease of 32,650 cattie compared with the amount sold up to the corresponding date last year, while the total now in stock amounts 687,000 cattie, that is, 107,200 cattie less than that of last year, the total decrease being 139,850 cattie, which is a much smaller difference than was expected. Such being the state of the tea market at present, it is generally believed that the export of tea will reach 22,000,000 cattie this year.—*Japan Times*, July 10.

PLANTING NOTES.

PARA RUBBER IN NORTH BORNEO.—We are interested to hear from Mr. H. St. J. Hughes of Labuan that he has two Para Rubbers doing very well in his garden—young trees in pot which he is sending up to Mr. Keasberry at Sapong to plant there. He has also given one to Mr. Hewett to plant in the Government House gardens and one Dr. Adamson has planted in his garden in low ground by the Calaghan Road so they will be able to speak with authority with regard to the tree doing well in Borneo before long.—*B. N. B. Herald*.

RED ANTS: A WARNING TO CACAO AND OTHER PLANTERS.—We direct attention to the important warning Mr. E. E. Green sends to his brother planters through our columns in reference to the "red ant." It has been drawn forth by the statement to us of a lowcountry planter that he was in the habit of carrying the red ant to his cacao trees in order to get rid of various minor insect pests. Mr. Green shows, however, that the risk of introducing other and worse enemies is too great; and we fancy our friend will after reading this letter, deem it wise to suspend operations.

MANURES FROM INDIA.—A correspondent writes to a contemporary:—"I enclose a chance cutting from the *Times of India* list of exports for one day this month which shows the brisk export of bone manure and oil cake now going forward from our Indian ports. The bone meal—2,000 cwt.—for Hamburg—is no doubt being sent to Germany for the beetroot crop raised under the bounty system by every device known to agricultural chemistry to the ruin of our West Indian cane sugar interests. If the Government of India had more, in fact a grain, of the science of agriculture in its composition, there would be an export duty put without delay on all items of plant-food before they were allowed to be taken out of the country to the impoverishment of its soils and deterioration of every British interest. This would not be open to the objections applying to export duties of an ordinary kind on raw produce. With the state the Indian soils are in there is no bone dust or oil cake whatever to spare for the enrichment of the land of countries outside.

FOR ALL INTERESTED IN "TEA."

There is a great deal of instructive, if not practical, information in this issue of the *Tropical Agriculturist*. First, we may call attention to the letter of our old contributor, Mr. John Hamilton, who, to experience as Ceylon planter and estate proprietor, has long added that of a London merchant and expert. Mr. Hamilton has always proved a good friend to Ceylon planters, and they will think all the more of him if his surmise in a private note to us, proves true when he says:—"It seems probable that we have now reached the end of unsatisfactory (tea) prices for the present." But to turn to his letter *re* the Bulking and Packing of teas, it will be observed that Mr. Hamilton throws quite a new light on the situation. He avers that much of the trouble arises from *overpacking* and occasional carelessness in re-firing, on the part of the Ceylon planter. The temptation to get as much tea as can be squeezed into each chest is, it seems, a very real one with some of our Superintendents and mischief results in several ways as pointed out by Mr. Hamilton. The latter is even doubtful if re-firing does not do more harm than good; while he is strong about the unequal gross weight of packages in a break. We commend the letter to the careful consideration of planters and should like to hear what "Senex" and some others think of it.

We have next to draw attention to the valuable review—given on page 195—by the *Investors' Guardian* of July 10th of the working of Indian and Ceylon Tea Companies for 1896, with reference to their value as an investment. Our contemporary has taken considerable trouble in the matter, and, as a leading Colombo merchant writes to us, "the article is well-written and the figures appear to have been carefully compiled." The comparisons and results cannot fail to attract considerable attention in this community. The surprising fact brought out by this examination of the accounts of 94 Tea Companies is that the total result shews a larger net profit for those belonging to Ceylon than for India, though "Ceylon teas do not reach anything like the high-water mark of the best Indian Companies." The highest average in the case of an Indian Company is 12.45d for the Assam, the net profit being 20 per cent on the ordinary shares; while in Ceylon, our highest average is 10.30d for the Nuwara Eliya Co., the net profit being only 6 per cent. But the *Guardian* editor should really have had a note to say that 1896 was the very first year of the latter Company and could therefore scarcely be taken as a fair criterion. At the same time there are high average (12.18d or 10.75d) Darjiling Companies which only pay 6 and less per cent. Nevertheless, the Indian Companies with fine teas show the highest percentage—11.62 p. c. as compared with 7.48 p. c. (medium class) and 9.17 low-class teas; while in the case of Ceylon the result is quite the reverse, the high-class teas averaging only 9.10 per cent. against 12.5 for low-class teas and 9.90 per cent for "Not classified." This is a matter which surely requires to be looked into in Ceylon, or the reputation of Companies owning high estates must be affected. As the *Guardian* says, "the Companies in Ceylon which have produced tea below the average of 8.25 d per lb. have given a much better result for the investor than the better class, the percentages being 12.5 for the former and only 9.1 for the latter."

We await the further article of our contemporary on the subject with considerable interest.

We have further to note the good feeling manifested at the annual meeting of the Indian Tea Association in London as to the joint Tea Campaign in America and the confidence felt in the good work done through the Agency of Messrs. Mackenzie and Blechynden. The *Grocer*—ever snarling at Indian and Ceylon, and unduly praising China, teas—has been at its old game it seems, while the editor also deprecates any further reduction in the British tea duty. Both this question and that of "bulking" are likely to be the subject of consideration shortly by Committees representative of tea interests in India and Ceylon.

 THE TRINIDAD GOVERNMENT
STOCK FARM.

The working of this establishment for the past year (1896) is reported to have been a moderately successful one. The following are some particulars relative to the dairy. The total output of milk was 133,151 quarts; the daily average number of cows milked was 64, and their yield 5.55 quarts per day. The yield, which is apparently less than in 1895, is said to be due not to any fault of the cows, but to the Colonial Hospital suddenly discharging its inmates in the middle of the year for the purpose of clearing the building, with the result that the demand for milk simultaneously ceased! On this account as many cows as possible were dried off to save feeding. The yield of the milch cow is regulated by the quantity required by the medical institutions. Any surplus after meeting these demands goes to the calves. As regards the feeding of the cows, rye meal was supplied all through without any ill-effect. With it was mixed "middlings" (a fourth crushing of wheat), cotton-seed meal, and coconut meal. The actual cost of the food, 8 lb. per day, is about 10 cents. The health of the cattle was satisfactory, the total mortality being 7 head, that is 1 cow, 1 bull, and 5 calves. The following remedy for ticks is recommended by the Manager:—2 gallons coconut oil, 1 quart kerosene, and sufficient Stockholm tar to colour well. This mixture will dress 20 head of cattle at, say, 3½d per head, if they are not too much troubled. It has to be well rubbed in with a piece of old sacking all over the animal. The price of milk in Trinidad as sold to the hospitals is only 5 cents per imperial quart.

We have referred at some length to the dairy as being that part of the Trinidad Stock Farm which is of most local interest, but it should be noted that the breeding of cattle and horses is successfully carried on as well. In writing to us, the Manager, Mr. C. W. Meaden, says that the year 1896 "has been fairly successful, though in all such establishments it must be expected that the success and profit will fluctuate. I enclose a photograph of a group of our milch stock. It is hard to define the origin of them, but they are the product of creole cows by Indian bulls ('Harrina'). These cows give 400 to 500 imperial quarts of milk per month and produce excellent working oxen." We thank Mr. Meaden for the excellent photograph and his satisfactory report, and wish the Trinidad Farm continued success.

TEA COMPANIES AS AN INVESTMENT.

Indian and Ceylon tea companies have lately attracted a great deal of attention, both from the remarkable development which has taken place in the industry during the last few years and also because of the very profitable nature of the enterprise. With a view to obtaining reliable data to guide intending investors in this class of shares, we have collected statistics of the result of last year's working from the balance-sheets of those companies which are open to the public, and which have already published their accounts for 1896.

There are several points of great interest in the history of the tea-growing industry of India and Ceylon, whether we regard it from a financial or from a political or social point of view. These latter have their bearing on the aspect of the subject with which we are more particularly concerned—that of the investors'—and therefore, they may with advantage be briefly reviewed.

In the first place that the industry is situated within the British Empire is an advantage upon which it is not necessary to dilate. The remarkable fact is that this tea industry of India and Ceylon is a comparatively new one, at least in its present dimensions, China having been in the past the great tea-producing country. Now, however, the teas of India and Ceylon have completely ousted China teas from our home markets.

Another feature for consideration in judging of the merits of the tea companies as an investment is the marvellous development which has taken place in the consumption of tea in the United Kingdom. The following figures, for the alternate years from 1891-5, taken from the last Blue Book, will show this in the simplest way possible, and will also indicate to what extent Indian teas have beaten China teas out of the British market.

	1891	1893	1895
India ..	109,637,790	115,022,926	123,361,870
Ceylon ..	61,900,075	72,630,852	83,447,792
China ..	171,537,865	187,653,778	206,809,662
	57,023,986	49,911,926	31,329,421

Total imports 240,779,331 249,546,451 255,360,128

The above observations indicate fairly well the present general position of the Indian and Ceylon tea industry. There are other and very important circumstances affecting the future; these will be considered later on.

We now come to examine the companies individually. The statistics given below, being the figures of the paid-up capital and the net profits for last year, have been collected by us from the accounts of ninety-four companies—all those which have, so far, been published, and of which we could procure a copy. In the majority of cases they cover the twelve months, January-December, 1896, but in many instances the accounts are made up to the end of the half-year, or to one of the quarters. In collating these statistics our chief difficulty has been to make the term "net profits" mean exactly the same thing in all cases. The different methods adopted in making up the accounts explains this difficulty. For instance, some companies deduct income-tax in order to arrive at the net profits; others do not. In the figures given below as net profits, income-tax has not been deducted, and where possible we have restored the amount in those cases where it had been charged as if it were an item of management expenses. This restoration has not been possible in every case. There are also variations in respect of allowances for depreciation and extensions of gardens out of revenue. These it has been impossible for us to remedy. We give the figures as accurately as we can; perfect uniformity is impossible.

In order to allow of convenient comparison we have kept the Indian and Ceylon companies distinct, and we have further subdivided them into groups, according to the quality of the tea produced, as shown by the prices realised—viz., high class, medium, and low class. The average price of Indian tea last year was 8-75d. per lb., and of that of Ceylon growth 8-25d.

per lb. In the case of the former we have taken as the margin for high class tea those which realised over 10-50d. per lb.; as medium, those selling at between 8-75d. and 10-50d.; and as low class those which fell below the average for the year of 8-75d. Ceylon teas do not reach anything like the high-water mark of the best Indian companies, and we have therefore made the single distinction—those ruling over and those ruling under the average of 8-25d. This classing is purely arbitrary. Only companies with paid-up capitals of £40,000 and over have been set out specifically:—

Company.	INDIAN.			
	Paid-up share capital.	Price per lb. 1896.	Net profit, 1896.	Per cent. ordy. shares.

Madulscema ..	96,700	—	2,033	—
Haputale ..	66,547	—	4,040	—
‡ Other Co.s (3)	48,949	—	4,602	—
	437,787	—	41,266	—
Total Indian..	4,730,523	—	447,197	9.45
„ Ceylon..	2,531,112	—	272,229	10.75
Grand Total ..	7,261,635	—	719,426	9.90

The striking feature in the above figures is the remarkable and uniform success of the companies, the normal dividends on the ordinary shares being from 6 to 15 per cent, whilst the average is 10 per cent. The 94 companies represented above have an aggregate paid-up share capital of £7,261,635, and the net profit on last year's working was £719,426, equal to an average return of 9.90 per cent. The Indian companies, representing an aggregate capital of £4,730,523, last year made a net profit of £447,197, or 9.45 per cent. The Ceylon companies, representing £2,531,112 capital, gave a return of £272,229, or 10.75 per cent, or 1¼ per cent more than the return on the higher priced Indian teas.

The classification according to the price of the teas produced on the various gardens gives some remarkable results. The Indian companies which produce the best class of teas have obtained a profit on an average of 11.62 per cent, and the cheaper teas gave a return of 9.17 per cent, the better class of tea yielding 2½ per cent more than the inferior quality. In the case of

Ceylon, however, the reverse holds good. The companies which have produced tea below the average of 8^s25d per lb. have given a much better result for the investor than the better class, the percentages being 12.5 for the former and only 9.1 for the latter.

What of tea-growing as an investment? The statistics given above point to it as being a very remunerative undertaking. Tea-growing, we believe, is a sound industrial enterprise, and although there are influences, both advantageous and disadvantageous, which will greatly affect the future of the industry and which need to be very carefully considered, under present circumstances we think the debenture stock and the preference shares afford opportunities for safe investment. An average return of 10 per cent on a total capital of 7¼ millions is sufficient evidence of the satisfactory security which the preference shares, at least, offer as an investment. A considerable proportion of this 7¼ million being preference share capital, the dividend upon which is fixed, the amount required for that dividend would be much less than 10 per cent, leaving a larger amount than a ten per centage for the ordinary share capital, which surplus constitutes, in effect, an annual reserve for the preference shares. In other words, the security for the preference shares in the aggregate in the above companies is very much more than the 10 per cent which the net profits seem at first sight to indicate. The ordinary shares are, of course, more liable to fluctuations. Their value as permanent investments will be inquired into in a subsequent article.—*Investors' Guardian*, London, July 10.

DUMONT COFFEE CO., LD.

The report of the directors of the Dumont Coffee Company, Limited, states that the profits for 1896 were guaranteed by the vendors at £120,000 which sum was duly paid to the company. After meeting expenses and writing off the entire preliminary charges, paying the debenture interest and preference dividend, and also a distribution of 10 per cent. on the ordinary stock, a sum of £83,506 is placed to reserve account, and £11,411, carried forward. The actual profits of the Companhia Agricola Fazenda Dumont for 1896, after providing for all outstanding on the estates, amounted to R2,444,024 \$694, which sum, calculated at the average rate of exchange, is equivalent to £92,605 sterling. This short fall in the profits is mainly attributable to the heavy drop in the price of Santos coffee, and to want of care and supervision in the harvesting and curing of last year's crop, owing to the ill-health of the vendor's manager. A large difference arises, moreover, in the conversion of the profits into sterling at the average rate of exchange for 1896, as against the rate at which the auditors based their estimates in the prospectus. The crop, which had been calculated at 80,357 cwts. amounted to 74,415 cwts. The directors were not in a position to exercise any control over the management of the property until the 1st January last. Since then steps have been taken to introduce a better system of management, and to add considerably to the machinery and appliances for curing the coffee crop. A considerable quantity of new machinery has been purchased, and some of it is already erected and in working order on the estates.—*Financial Times*, July 9.

COFFEE PLANT DISEASE.—A Nilgiri correspondent writes:—"The comparatively dry weather that has prevailed in the southern and eastern parts of the Nilgiris has developed a serious attack of leaf disease on coffee estates and the planters are anxious that some investigation should be made by Government."

Correspondence.

To the Editor.

SALT FOR AGRICULTURAL AND PLANTING PURPOSES.

Franklands, Veyangoda, 13th March, 1895.

The Hon. the Colonial Secretary,

SIR,—1. I beg that you will place before His Excellency the Governor this my application for five tons of salt, to be used in certain agricultural experiments on this estate.

2. The manurial value of salt in agriculture is well-known; but so far as I am aware, the quantities in which it may safely be applied to land, the particular crops to which it is most beneficial, and the duration of the benefits which may follow on an application, have never been ascertained, at any rate locally.

3. A few years ago there was considerable discussion in the local newspapers, on the special value of salt as a manure for coconut estates situated at a distance from the sea-border where coconuts are known to flourish best, presumably owing to the presence of salt in large quantities in the soil, and to their being under the influence of salt-laden winds. My recollection is that an application was made by the Agricultural Association, which has ceased to exist, for the issue of salt at cost price; but the then Government felt itself unable to accede to the request because of the difficulty of denaturing salt, so that it might be made absolutely unfit for human food.

4. Since then the island, or to be more accurate the districts in which coconuts are most extensively cultivated, have passed through two successive years of drought, which have told disastrously on coconut estates and coconut crops; and it has occurred to me that experiments might establish, that the use of salt as a manure might minimize the evil effects of droughts, by rendering the soil more retentive of moisture—the hygroscopic properties of salt being well-known. It is the desire to carry out these experiments, not wholly from disinterested motives, which impels me to make the present application; but I do not ask for a free issue of the salt, though if it were offered I should not decline it, as I shall have to incur some expense in connection with the experiments. I am prepared to pay the cost price of the salt, or the price at which it is sold for exportation.

5. The application that salt should be issued for a local experiment, which may be fraught with immense benefits to a national industry, at the same price at which it is issued to strangers to be carried away from the island, cannot be justly regarded as unreasonable; but it may be as well to anticipate two possible objections.

(a). If it be asked what guarantee is there that the salt thus issued or a portion of it, may not be used for food, to the detriment of the revenue, my only reply can be a personal undertaking that the salt shall be kept under lock and key, and applied under my personal supervision, mixed with cattle manure, or some compost, and so dug in, as to be practically inaccessible for food.

(b). To the objection that assuming the experiments to be successful it would be impossible to denature salt, issued for agricultural purposes as to render it unfit for food, I answer that it may be so. I am not aware that ex-

periments have established that salt can, by mixture with other ingredients, chemical or offensive, be rendered absolutely unfit for food; but it would be wiser to deal with probabilities than mere possibilities in the practical issues of life. Every planter knows the difficulty there is in getting coolies to handle, or even to manure, manures offensive to the smell and suspected to be mixed with excrementitious matter. Is it then in the least degree probable that even the most needy or foul-feeding cooly will wash small crystals of salt clean, in order to use it for food? Assuming that a certain proportion of labourers may do so, to what extent will the revenue be damaged by their erratic and exceptional proceedings? Probably not to the extent of £10 a year.

6. It seems to me therefore, quite practicable to issue salt of a quality unfit for human food, or so treated as to render its use for food practically impossible, and under guarantees from the purchasers which shall protect the revenue; but assuming that these safeguards may fail, it would be absurd to assume that it will fail in every case, and that every purchaser of salt for agricultural purposes will risk criminal consequences by turning retailer of salt. The loss to the revenue, if any, is likely to be trifling, and caused chiefly by speculation. But as against that must be placed the immense benefit it would be to the whole country, if its productiveness can be increased even by one-twentieth, by the use of salt as a manure, and if its herds can be protected against sickness by the free exhibition of salt.

7. If it once be established that salt can be applied with appreciable benefit to the land, the Government may find it possible to sell salt, without any restriction as to its uses, at a reduction in price, which, through the increased consumption, will ensure the same direct revenue, while indirectly the revenue will be greatly benefited by the greater productiveness of the soil, by the improved health of the people as a result both of more abundant food and cheaper salt, and by the greater immunity of cattle from sickness.

8. I have said thus much to show that my experiments if they establish that salt would be decidedly helpful to coconut cultivation, will be very beneficial to the country at large and will not imperil the revenue. I beg that His Excellency may be pleased to give my application favourable consideration. If necessary, the experiments may be carried on under the direction, or on the advice, of the Superintendent of the School of Agriculture, so that results might be carefully noted.—I have the honour to be, sir, your obedient servant,

FRANCIS BEVEN.

Colonial Secretary's Office,
Colombo, 5th April 1895.

FRANCIS BEVEN, Esq.

SIR,—I am directed to acknowledge the receipt of your letter of the 12th ultimo, applying for 5 tons of salt, to be used in experiments to test its value as manure, and to inform you that the matter was duly laid before the Governor.

2. In reply, His Excellency desires me to say that personally he would have no hesitation in trusting you to carry out your experiments; but that, if salt were so issued on a large scale to as many persons as desire to buy it, the privilege would be abused to the detriment of the revenue. The Government would, therefore, in granting your request, be exposed to a charge of favour-

itism, inasmuch as the desire to safeguard the public interests would certainly dispense the Government to refuse similar applications from many others.

3. As regards paragraph 5 of your letter, I would refer you to the *Government Gazette* of May 1st, 1869, and would further point out that a cooly who had cleansed salt of its impurities and rendered it marketable, would not probably consume it himself, but would sell or exchange it in the bazaar.

4. It may be mentioned that in 1887, a similar application from a well-known member of the Mercantile Community in Colombo was refused on the same grounds.

5. His Excellency regrets therefore that the Government is not in a position to meet your wishes.—I am, sir, your obedient servant,

H. L. CRAWFORD, for Colonial Secretary.

COCONUTS AND SALT.

Veyangoda, July 15.

DEAR SIR,—I was much interested in Mr. Cochran's report on his analysis of coconut husk, (see page 173). The manurial value of the husk is well-known; and even villagers bury or dig in the husk round coconut trees. As a rule, however, they prefer to spread it on the surface round a tree, but more frequently they let heaps of husk rot *in situ*. This neglect of a valuable manure is not always due to ignorance of the fact that it is a manure. Heaps of cattle manure, whose virtues the most ignorant will not deny, may be seen similarly left unapplied. The neglect is generally due to two reasons—1st, idleness, or unwillingness to trouble oneself to transport and dig in the valuable stuff which is all there, and with which no one will run away! And second the superstition that manures are ultimately hurtful to a tree—that if once applied, its discontinuance will be injurious if not fatal to the tree; but I have never been able to get an answer to the question, why one should discontinue the use of a thing proved to be profitable. Any way, even the occasional and infrequent application of the husk, in however primitive a fashion, is evidence that it is recognised as a manure; and I presume, the soil derives the benefit of the same constituents from the husk, whether buried or reduced to ashes—only in the former case the absorption of the manure is much slower. Mr. Cochran's interesting and practical investigations are of special value, because they furnish accurate information on the constituents of the husk ash; for though he deals tenderly with the analysis which Messrs. Davidson and Lepinc have published, the great difference between his and their figures cannot be entirely explained away in the manner he suggests. But even his more modest figures prove that a ton of the crude ash is worth R80, and that the husk of 65,000 nuts would produce that quantity, giving about R124 as the value of 1,000 husks for their potash and phosphoric acid alone? I was at first under the impression that it was a ton of potash which was valued at R80. That would have reduced the value of the husks to about one-third the price stated; but on re-reading Mr. Cochran's calculations, I see I am mistaken. On his showing, proprietors part with husks at much below their manurial value in selling them to fibre mills, but the question remains, will the mills be able to afford to buy them at more than their value as a manure?

The coir fibre and bristle trade is believed to be overdone, and the margin of profit is said to be very small. What would the effect of a rise in the price of the raw material be? Then, I suppose, analysis of the soil alone can determine whether it needs all the constituents which the husks taken from it yields, and whether its needs may not be more efficiently and economically supplied in other ways. Then again, there is the further question—how much of the manurial constituents is taken away by manufacture, and how much remains in the refuse coir dust? The dust is known to be an excellent deodorizer, and its efficacy as a defensive armour for ships between plates or planks has been asserted. If its ashes contain an appreciable proportion of the constituents which the husk has been credited with by analysis—then estates may take back the dust after selling the husk! and, who knows how much more that is valuable in coconuts and is now allowed to run to waste, may be rescued by science for the benefit of proprietor and manufacturer?

Though I have not systematically reduced husks to ashes, I have used them largely to pack trenches and to fill up depressions with good results; while I have sold husks to Fibre Mills only when carriage was practically free. That is whenever I send my carts for roadside cattle manure, I send them laden with husks if available. Otherwise husks are retained for application to trees. After Mr. Cochran's letter, it is a question to be considered whether I gain any advantage, and how much, by exchanging a cart of husks for a cart of cattle manure. Curiously, only last week when I had the pleasure of taking the Director of Public Instruction over this place, we discussed the uses of husk, and I mentioned to him its richness in potash, and made special reference to the sharp taste of the ash and its resemblance to saltpetre. I had no analysis in view then, but as Mr. Cochran states that no wood ashes he has ever analysed had more potash than the ash of coconut husks, I would ask him whether he has ever analysed the lantana bush? I have a recollection that Mr. Dixon, the first Science Master of the Royal College, found lantana the richest of all vegetable substances in potash, but Mr. Cull was unable to confirm my impression.

Then, there remains the question of salt. Its presence in such large quantities in the ash—two-fifths of the weight—is additional reason for the use of husk as manure, especially in inland districts; but I must reserve what I have to say on salt for another occasion.

Faithfully Yours,
F. B.

"ASH OF COCONUT HUSK"; AND VALUE OF SALT AS A MANURE.

Colombo, July 17.

SIR,—Referring to your correspondent's remarks as follows—"I would meanwhile point out that Mr. Cochran's calculations are rather out. Has he not taken the weight of ash in working out the value of the potash?"—I would reply yes, certainly; but not in such a manner as to "enhance the value of the husk 3-fold." The value put on the crude ash is simply the value due to its contents of potash and phosphoric acid, so that there is no mistake. The question as to the value of common salt as a manure has always been a disputed one;

men like Liebig, Lawes, Warrington, and Voelcker declaring against it; although Dr. Voelcker (according to Dr. Griffiths) latterly recognized its value as a manure which increased the yield of wheat, barley and oat crops. There is no doubt that in special cases salt is of use as a manure. Thus Dr. A. B. Griffiths states that from his own experiments and experience, a dressing of $\frac{1}{2}$ cwt. nitrate of soda, and $\frac{1}{2}$ cwt. salt per acre, forms an excellent manure for mangold-wurzel. From the evidence before us, I am disposed to consider the coconut tree as one of the special cases in which salt is useful as a manure.

Dr. Griffiths sums up the general properties of common salt from an agricultural point of view as follows:—

(a) The property of salt, in small quantities, in promoting the decomposition of the animal and vegetable matters contained in all cultivated soils is considerable

(b) It acts as a *direct plant food* in small proportions.

(c) It has the power of destroying noxious insects, slugs and weeds, when applied to fallows.

(d) Salt possesses stimulating powers on growing plants.

(e) It has the power of preserving the juices of plants, and the soils in which they grow from the effects of sudden transitions in the temperature of the atmosphere (C. N. Johnson, F.R.S.)

(f) "It increases the power of certain soils of absorbing moisture from the atmosphere."

I may mention, in conclusion that, according to the same author, salt has been used as a manure in Palestine and in China for more than 2,000 years.

M. COCHRAN.

SALT AS A MANURE.

July 26.

DEAR SIR,—The discussion on the use of salt as a manure is one deserving of consideration. I have noticed that seaweeds are largely used in England as a manure, and consequently trees and plants which grow near the coast in the island may improve by the addition of salt to the soil. It has been proposed from time to time to reduce the Government price of salt for agricultural purposes, and to so adulterate it as to render it unfit for human food. According to a reasonable way of putting the matter it is anything but just and equitable to raise the price of salt for the food of man and to reduce it for the food of plants. What would be said if the Customs charged a higher duty for paddy imported and used as food for human beings, and lessened the duty when imported to feed dumb animals. Such a proceeding would not for a moment be countenanced by Government.

As far as I know the quantity of salt for a coconut tree need not be very much, one seer or measure, or a little more, would be sufficient for each tree. A bushel contains thirty-two seers, I think, and this may suffice for thirty-three young coconut trees, but older trees may require a little more. If one-third of the price of a bushel of salt be reduced it would answer both for agricultural purposes and as a necessary of life. Of all the taxes on food the most unjust one is a *salt tax*.

The salt which is annually destroyed may be collected and used. Those who have noticed the manufacture of salt, and also the natural crystallization of it in salt pans, or little lakes called leways, would have observed that if soon after the crystallization of salt it is not collected, long

crystals shoot between the square crystals of common salt and render the salt bitter and unfit for human food. The long crystals are those, I think, of glauber salt, or sulphate of soda. Salt of this kind may well be collected and sold cheap for agriculture. The mixed salt is too bitter for food and not easily removed from common salt; and the cost of doing so would be expensive and not worth the trouble if salt for food is made cheaper. This would at once remove the difficulty of adulterating salt so that it may not be used as food.

One time salt was sold cheap, or in reduced price, for fish curing yards; but there have been such restrictions that the fishers gave up curing fish in the yards or huts kept by Government for the purpose. It is a pity that more encouragement was not given to this industry, as it is believed that badly cured fish as a diet, is very unwholesome and apt to produce disease.

—Yours truly,

X.

[We quite agree that it will be a happy day for the mass of the people when the salt tax can be reduced or abolished; although it is questionable if people in remote districts could even then get salt cheaper than it is now given by Government. But the principle on which salt is wanted free for agriculture is that it may increase the production of food staples.—ED. T.A.]

SALT IN AGRICULTURE.

DEAR SIR,—It is a matter of great satisfaction to me to find that the agitation I started about ten years ago for the use of salt in agriculture in general and in coconut cultivation in particular, receives support now from you after the analysis of Mr. Cochran revealed the fact that salt in large quantities is to be found in the products of the tree. I received no support from you at that time as you shielded yourself behind the analysis of Lepine and the opinion of Dr. Trimen that the small quantities of salt vegetation required was supplied by the storms of the S.-W. monsoon.* The aspect of affairs has changed now that Mr. Cochran has proved the unreliability of Lepine's analysis as regards husks. What about the other parts of the tree? Will not the moribund National Association do a "national" duty by a product of "national" importance and have complete analysis made of all the products of the coconut tree after the manner of Lepine's tables.† My agitation of 10 years ago started in this wise, coconut leaf disease was receiving attention. It was found chiefly in inland districts‡ where coconuts were not growing under natural conditions as regards situation and soil. I suggested that possibly the cause of the disease was due to this and that it would be wise to restore natural conditions as much as lies in our power by systematic application of salt to the coconut tree.

* We cannot understand to what our correspondent refers. In the very first edition of our illustrated Handbook "Ceylon in 1883" and in every edition since, we have placed the releasing of salt from tax for agricultural purposes, as one of the reforms of the future to be kept steadily in view. "B." must be referring to some remark of our "senior" during our absence from Ceylon? But on the general question of free salt for agricultural use, we know he also wrote favourably so far back as the "sixties."—ED. T.A.

† How is a "moribund" institution that has not paid its debts, to do this?—ED. T.A.

‡ It was very bad in Slave Island near Galle Face.—ED. T.A.

If I mistake not Mr. Francis Beven then, for the first time, applied to Government for salt to be issued to him for experimental purposes at wholesale price. In reply he was asked for figures of the probable consumption of salt for agricultural purposes if issued at reduced rates. Of course he could not answer so unreasonable a question unless all agriculturists became specially communicative and confided their probable requirements to him. Then the matter dropped.

The reply to Mr. Francis Beven's reasonable and modest request of 1895 does not redound to the credit of Government as far-seeing, paternal or practical. The objections put forward are fanciful. No cooly will purify contaminated salt to sell it. He will hardly find a purchaser for it when it will be known far and wide that contaminated salt is being used on the estate he hails from.

I attempted to revive the agitation for the use of salt in coconut cultivation so lately as last year and quoted numerous authorities in support of its use in agriculture. My communication was published in the *Observer* without one single word of comment,* and it led to no correspondence. I gave the matter up in disgust as no one danced to my piping.

Now as to the method and time for application. Salt being so soluble it will not be advisable to apply it even in heavy soils except as a top-dressing and with the last rains of the S.-W. monsoon. Owing to its power of attracting moisture from the atmosphere, it will be helpful towards enabling the trees to pass through the trying period of drought. For districts suffering from drought and where it becomes necessary to water not only coconut plants but trees as well, its use cannot but be of the utmost use. My guiding principle in cultivating a coconut estate is to let no product leave it but what is essentially necessary for financial purposes and to get into it for application to the soil all I can. I for a time successfully resisted the wish of a former employer to sell his husks to fibre mills. He said I could get a return load of fibre dust. I was for getting the dust in addition to keeping the husks. His wishes or orders as supreme prevailed in the end. I feel sure after Mr. Cochran's analysis of the husk he must feel sorry that he allowed so much valuable manurial matter to be removed from his estate and for only a small consideration. I think Mr. Cochran's calculations should not be the means of inducing intelligent planters to sell their husks if they get an offer for them above what they are worth as a manure. All waste products should be returned to the soil, after burning, as a rule, for substances that decay slowly. Of course, there is a loss of organic matter by this, but that is compensated for by the quickness of the results.

The richness of husks and branches in potash is well known to Ceylon dhobies though they are not chemists and they take practical advantage of their knowledge to the destruction of our clothes. In the Western Province the ashes of husks is used in the place of soap to wash clothes, and in the Southern Province that of the branches, or rather petioles. After rain had fallen on burning branches I have picked up ernde potash in white crystals very sharp and corrosive to taste and touch.

B.
[The agitation to enable Ceylon salt to be used for agricultural purposes, began first in 1856, within our time, and has been renewed at intervals since.—ED. T.A.]

* In our absence again unfortunately!—ED. T.A.

THE CACAO DISEASE.

Suduganga, Matale, 10th July, 1897.

DEAR SIR,—In solicitation of practical experience in the matter, and under this to elicit as far as possible what may be the cause of the disease which attends the Common Red variety of Cacao at a certain age, would you kindly publish the enclosed Correspondence.—I am, dear sir, yours faithfully,

GEORGE A. GREIG.

Mr. G. A. Greig's letter to Mr. Green.

Suduganga, Matale, June 28th 1897.

E. E. Green Esq., Pauduluoya. Dear Sir.—I was very glad to see from your letter of the 21st in the *Observer* of the 23rd you were of opinion that the present causes of the disease affecting our cacao were not directly traceable to any insect.

I have a theory on foot that the spread of "canker" has been entirely due to having cut off suckers, which I base on the following points—1st. I notice in cases where old trees have been allowed to grow with very little suckering or none at all, these remain (so far) healthy and are for the most part not subject to disease;

2nd. That canker predominates in the better cacao where soil is richer; and 3rd. that the poorer cacao besides being unaffected looks better than it ever did.

Taking the 2nd and 3rd points into question I can only arrive at a reason for the diversities in these, in the following:—That cocoa in the richer soil having borne abundant crops, and the limbs in consequence (being unable to extend or renew themselves in time owing to suckering) were in a weak state, and diseased (and thereby subject to the attacks of insect and fungi) resulting in mortality. That the poorer cacao not having dropped to the extent of the other, though subject to the same treatment in every way, the limbs were in healthier condition enabling the trees to withstand the attacks of insects and fungi as well as respond to last year's favourable weather.

I agree with you that the branches of a cankered tree, as a rule, are not affected, and this goes to prove, I would think, there is no infection in the disease.

It is well known, or it may not be, that branches renew themselves, and are auxiliaries to one another in different periods of fruiting, and cacao being a stem-bearing tree, so also, I maintain should stems have the same advantage in not being suckered at all at any time to either elongate themselves or that the tree have two or three limbs from the bottom as nature may provide. In having an increased number of stems or limbs (the latter term properly speaking, and I borrow this advantage after reading your letter of the 21st), this would mean a further development of primaries (?) secondaries, &c., and equalize the fruit bearing area, and possibly prevent trees over-bearing. And it is to over-bearing on the one limb I attribute weakness. I notice that if a tree does not give much crop in the autumn it generally responds in the spring and *vice-versa*. In the same manner this may account for extra cropping every alternate year.

Of course the question now is in the present causes of disease in old cacao,—What is the best course to pursue for a cure?

In the theory I put forward the only answer is let all suckers grow. But (that inevitable!) in cases where the trees have been subject to a severe treatment of suckering it will take at least two years or perhaps longer to prove the remedy. And this inasmuch as suckers will require the time to mature and assert themselves from the roots, and no tree will be safe till it has a limb auxiliary either in extended form or in two or more stems. Likewise suckers will die with the old stem or limb if their growth is not well advanced.

I know of cacao trees (Common Red variety) which have been allowed to run up and to all appear-

ance have not been suckered, and (these for my "idea") I would not wish to see better.

I should be much obliged if you would kindly let me have your opinion on my views. And you can make what use you like of this letter if it will be of assistance.—Yours, &c.,

(Signed) GEORGE A. GREIG.

(Mr. Green's letter in reply.)

Eton, Pundalooya, July 2nd.

GEORGE A. GREIG Esq., Suduganga, Matale.

DEAR SIR,—Please excuse delay in replying to yours of 28th ult., but I have been very busy the last few days, and could not find time to give your letter the attention it deserved.

I will commence by repeating part of a circular which, in conjunction with Mr. Willis, I have drawn up for distribution through the cacao districts. It runs as follows:—"From personal examination (on the spot) of a large number of diseased trees, we are led to the conclusion that the canker is the outcome of some obscure constitutional disease or weakness, the cause of which is still undetermined (whether due to fungus, to over-cutting, insufficient shade, or old age); but that it cannot be directly attributed to the work of any insect. The diseased patches on the bark were frequently found to originate quite independently of any insect attack; though any wounds, unclosed knot holes, or insect borings were found to aggravate the disease by permitting the water to enter and permeate the inner layers of bark. On the older and weakened trees, a very large number of the cankered patches were distinctly traceable to open knot holes where suckers or branches had been torn off—affording lodgment for water and small insects. On young and vigorous trees all such wounds were repaired by a renewal of the bark. We should be glad to know how far these observations agree with your own."

Now returning to your letter,—briefly stated, your theory seems to be that canker is mainly due to the practice of suckering the trees. And you base your argument on the supposition that cacao trees in good soil are weakened by over-bearing, and are not allowed to recoup themselves by the free growth of fresh wood.

I think there is a great deal to be said for your theory—and on more extended grounds even than you give. As you will note by my earlier quotation I am of opinion that the disease is the outcome of weakness, and though I was not in a position to make the assertion, I personally suspected the weakness to be largely due to over-cropping which sapped the vitality of the tree and besides predisposing it to disease, prevented the healthy repair of wounds.

It is a very general rule, which is being constantly corroborated, that the more vigorous the growth of a plant, the less liable it is to attack from insects or other pests. It is when the flow of the sap is retarded or its nature altered by weakness or other causes, that the plant falls an easy prey to blights of all kinds. It is evident therefore that a system of reducing or concentrating the cropping area, which necessarily exhausts the plant, would predispose it to the disease.

Not being myself a cacao planter, I am not able to speak with any authority upon the actual methods of cultivation of that particular product; but from an outside point of view and from observations made during the examinations of this disease, I should think it would be more profitable to encourage the growth of several stems or limbs than to confine the tree to one main stem. I noticed during my recent visit to Matale that though these old stems continued to produce flowers, very little of this blossom actually produced fruit in such situation, the bulk of the crop being borne on the more vigorous limbs and branches. My investigations also plainly showed that the canker was practically confined to the old weakened stem. Young trees and the more vigorous-growing Forestero variety were almost entirely free from the disease. Have you ever tried stumping the young plant to induce it to start several stems from the base? With regard to your suggestion to entirely stop the practice of "suckering," I should think

there must be a limit to the number that could be left with advantage, but you on the spot must be in a better position to decide that question. But wherever suckers have to be removed, the work should certainly be done carefully and the wound stopped with some waterproof mixture.

Although with careful treatment, such as you suggest it may be possible to keep the red cacao free from canker, still there seems to be no doubt that the Forestero is a much hardier plant and more capable of resisting disease of all kinds. Attention cannot be too strongly drawn to the advisability of selecting hardy disease-resisting varieties in any cultivation. It is a most fortunate circumstance that there are such disease-resisting stocks in so many cultivated plants. In the low-country of Ceylon the immunity of the Assam indigenous tea from *Helopeltis* is most marked and convincing. Particular varieties of potatoe were long ago found to be more or less proof against the potatoe disease; and rust-resisting varieties of wheat have been most successfully cultivated in Europe. In the case of Phylloxera the scourge of the continental vineyards, particular stock was found that resisted this insect pest, and though the fruit of this variety was not so profitable as that of the more delicate vines the difficulty was overcome by grafting the more valuable variety on to the hardier stock. This last hint might perhaps prove valuable to cacao planters. It would be interesting to try the effect of grafting the more delicate Red cacao to a hardier Forestero stock—Yours &c. (Signed)

E. ERNEST GREEN.

CACAO DISEASE.

Crystal Hill, July 21st.

SIR,—Mr. G. A. Greig of Suduganga, Matale, whose correspondence with Mr. E. E. Green, on the cacao disease now prevailing appeared in your paper, will be surprised to hear that his next door neighbour so long ago as the year 1890, discovered that it was a mistake to remove the suckers and gormandizers from the cacao tree as it not only tended to weaken the tree by depriving it of its "breathing lungs;" but also helped the old wood to harbour insects which eventually destroyed the trees. But the then proprietor of this property, the late Mr. A. G. K. Barron, like many other planters, did not believe in it. Two years after, great mortality ensued among the cacao in the district, and it was attributed to a deficiency in the rainfall and want of more shade to the trees. Everyone then resorted to planting dadap trees as shade. The year following was no better both with regard to the rainfall and the disease; but just then this property became my own, and enabled me to put my theory into practice at once. The result may now be seen by any one who wishes to do so, and the visitor will be well repaid for his trouble when seeing that while the mortality is still continuing among my neighbours, I am enjoying a perfect immunity from it.*

Mr. J. H. Barber paid me a friendly visit two years ago, and surprised me not a little when he observed that I was doing just what he had also been doing on his property, "The Grove" Ukuwala, i. e. he allowed the cacao tree to grow according to its natural habits. He had been to the West Indies, the home of the cacao plant, and had seen for himself that this was the law there.

It would be presumptuous on my part, though a planter of 20 years' standing, to express any opinion bearing on the scientific notions of Mr. Green; but since that gentleman has had the modesty to acknowledge that he himself was not a cacao planter, I make bold to remark that if by grafting (as he suggests) the delicate Ceylon or Caracens over stocks of the hardier Forestero, we succeed in producing a disease-resisting variety of cacao, still I doubt that the pro-

* We should like to know if Mr. Vanstarrex means that diseased Red Cacao trees after allowing suckers to grow, fully recovered?—ED. T.A.

duct of the grafted tree would any way be superior to the pure Red Caraccas with which Ceylon always topped the market. Anyone examining the contents of a Foresteropod will perceive that the beans are much flatter than those of the red pod. The latter is the variety that produces the nice and plump bean, and it is this plumpness that gives tone to our produce. Scientific treatment may overcome diseases and pests, but never improve the quality of the product. Our endeavour should therefore, be entirely directed to preserve the purity of our red cacao. This could easily be obtained by allowing the plant to grow in its natural wild state with, of course, the usual help given to nature by the agriculturist. Mr. Green is careful to caution us with regard to the number of suckers allowed to grow; but in my opinion the placing of a limit to the number of suckers grown is likely to do more harm than good. For the fact is that when a superabundance of suckers springs from the tree, only a few takes the lead—following, I suppose, Spencer's theory of the "survival of the fittest"—and the rest linger for a while and die off. And if it is desired to leave only a few suckers to grow and remove the superfluous ones, who is to distinguish the fittest from those which are unfit to survive? There is no room here to even err on the right side; so we better leave it to nature.—I am
A. VAN STARREX.

RED (CARACCAS) CACAO RECOVERING ON SUCKERS BEING ALLOWED TO GROW.

Crystal Hill, July 24th 1898.

DEAR SIR,—In reply to your query whether "diseased Red Cacao trees, after allowing suckers to grow, fully recovered?"—I assure you that such has actually been the case in my experience where the so-called disease had been only an insect attack. I am unable to say whether the tree had any other disease. Neither could I detect any disease in the Red Cacao trees that are dying on some estates in my neighbourhood other than insect attacks. These insects are in various forms as weevils, caterpillars, wire worms, gubs *et-cetera* which infest the old wood. The infested wood decays gradually when white ants or termites begin to invade it, and finish the work of destruction which the weevils and company had begun. It is remarkable that the insects do not attack new wood. To my mind it seems the attack begins just as the bark attains a certain degree of maturity; but its baneful influence does not manifest itself until it is too late for curative remedies to be of any good. Hence it should be understood that a tree incurably attacked, the suckers—if any could be got to grow on such a tree—would be of no avail. But if that tree had had its sucker growing from an earlier stage of the attack, it is the infested wood that would have gone off and left the sucker to take its place, which again as time rolls on will be attacked by the insects and die off, leaving its place for another successor. It should also be noted that a sucker growing from the stem nearest the ground strikes root and becomes a new tree. Apart from this suckers growing higher up or over the branches—which in the planting parlance are known as gormandizers—are also not to be despised, for they create new arteries in the stem and roots of the old tree and transform it to a new one. Also observe the attacks of *helopeltis*, the branch dies backward till a joint is reached, whence a new shoot springs out and fills the place of the decayed portion. The same law of nature obtains in every other case.—I am, &c.
A. VAN STARREX.

"CACAO SPEAKS."

Sir,—I have no disease—canker, etc. I have enemies:—The *Helopeltis* and the Paddy Fly (sap-suckers from small branches); the Red Borer (puncher=bad pruning, over-bearing); since the Red Cotton Beetle which perforates the leaves and unripe seed; the Planters' Indifference (bad plants and badly planted in different soil.)

The *Helopeltis* and Paddy Fly come in swarms at times and suck my sap from the tender branches at edge of leaves.

A mixture of sulphur $\frac{1}{4}$, fresh dolomite lime 1, powdered wood ash 3—well mixed and thrown over and throughout the tree either after a shower or early in the morning when leaves have dew on them, will keep the *Helopeltis*, Paddy Fly and Cotton Beetle away and this application will strengthen leaf and small branches.

The Red Borer—you should catch the moths in May and June before they lay their eggs; later on you have to watch the trees and as soon as you find the borer at work supply some coolies with a piece of wire and then push in the hole and kill the borers—let him dip it in margosa oil, stop up the hole if you cannot even reach the insect, the smell and no ventilation or egress to carry out its own excrement will soon kill it.

You make such a cry out against poor *Tomieus*; he would never come near me if not for your plauters; and why:—

1. You get and plant unripe as well as over-ripe seed, sometimes in soil without lime and potash. You should remember I require both lime and potash especially in my infancy, same as a child requires milk.

2. Coolies are not always careful when taking me up with transplantor or with baskets and put me in the hole anyhow to get their day's task completed. In this injured or crippled state, I cannot draw up sufficient nourishment to form a healthy tree without some help from you which, however, you decline to give—though in your walks round, by the colour of my leaves and their blotchy seedy bark stems, you ought to see that I am suffering from certain wants, not disease.

3. You are so anxious to secure crops that often when I am still young and afterwards when older you allow me to bear more fruit than I can carry and cannot shake off (spirit willing but flesh weak), when you should relieve me of some of the fruit or give me stimulating food to enable me to ripen that crop without suffering in body, not being able to supply the whole tree and fruit with sap, especially when *Helopeltis* has injured the leaf and twigs and thus stops their help in taking nourishment from the atmosphere and return same with sap, part of the fruit and branches will die and even stem gets bark-bound.

You at times plant me in a soil totally unsuited for me to live and thrive in, soil too poor, a subsoil of clay or rock exposed to much hot wind at one season then to much cold with gales at another season; while so placed I cannot supply sufficient sap for fruit and body, and stem gets also bark-bound.

When bark-bound the juice with fibre between outer bark and stem turns sour, then decays. *Tomieus* is a great drunkard and soon smells the decay in the sap and then bores holes in the bark to get to the sour sap; when no more between outer bark and stem, then bores into the wood which by this time also gives out sour sap.

You also allow me to be handled rather roughly. You know I am a delicate plant, yet you allow the coolies to pull off suckers and hack off branches, leaving the rough cut to decay and the insects to follow up the decay, whereas you ought to have made a clean cut and covered my wound with a mixture of oil and tar. It is not necessary to stump me to start several stems from the base; it is one of my failings to throw out young shoots continually if all these were allowed to remain, I should very soon be choked wanting more sap, than the roots and leaf and twigs can supply and then decay will also set in; but when one or two suckers only are al-

lowed then these will become very strong—even part of the stem below these suckers gets enlarged; such make a hardy tree and after a time you can cut down the old tree—so lose no crop—but you can saw off the old tree eighteen inches above ground and then allow one or two of the lowest (if two, one on each side) suckers to grow—only always cover the cut on old tree with a waterproof mixture of tar and oil to prevent sap oozing out and insects to come to the sap; after it becomes sour then they would bore into wood, &c.

CACAO.

TREE PLANTING AND CACAO.

13th July 1897,

SIR,—“*A revolution in tree planting*” is very interesting reading. It must be very encouraging to old coffee planters to know that the system had been anticipated and practised by them almost from the beginning of the era of coffee cultivation in Ceylon. The system of root pruning and cutting of the plant was known as “stumping” and the plants so treated were known as “stumps.” I believe the system originated by the planter making thoughtful provision in his nursery for plants both for the actual planting of his clearing and for supplying. The planting was done during the S. W. monsoon and the supplying during the following N. E. and S. W. monsoons. The plants for supplying having been found to have far out-grown the 6 to 9 inches in height, supposed to be the orthodox height, stumping was resorted to save transport, the too great shock to the transplantation of large plants and chiefly to prevent injury to the plant by the tearing up of the tap-root and primary roots. The system was found to answer well and supplying was always done with stumps. They were found to be hardier than plants, and when the usual monsoon rains failed, they stood a better chance of growing than plants.

The same care of and attention to the pruning of roots was not given by the planter as is directed by Mr. Stringfellow. An ordinary cooly was set to the task with a pruning-knife. He held the plant top upwards and first pruned the tap root and then the side roots, cutting at each stroke as many as would come between his thumb and the knife. We are now advised to hold the plant top-downwards and cut the roots, so that when planted the cut surface will be downwards; for “experience has shown that these roots are generally emitted perpendicularly to the plane or surface of the cut.” Whether this was a necessity with a surface feeder like coffee is a question, but with a deep feeder like tea there can be no question that it should be carefully followed.

I wonder whether anybody has tried stumping cacao. It is considered a very delicate plant and a non-disturbance of its roots at planting essential to successful growth. The general belief was that cacao was one of the most difficult plants to raise, but once established that it grew on for ever and was as hardy as a jak tree, as I once heard it described. With the experience of the Boring Tomicus, all that is changed now and cacao is thought to be hardy only after 20 years' growth.

I have a religious love and regard for everything old and it grieves me to read that the old red variety of cacao is condemned as delicate and its supersession by the Forastero suggested. It cannot be so very delicate after all, for there are trees of great age still existing in Ceylon. There are some very old trees at Mango Lodge,

Kandy, facetiously called Graves-end, opposite the Military Hospital. If I mistake not, these trees have been alleged to be the parents of the trees on the Doonbera plantations. At the “Dewala,” Badulla, there are also some old trees and when Mr. Sproule was residing there, the pods were freely requisitioned by the planters on the surrounding estates. At the Mansion, Grandpass, Mr. De Breard has very old trees growing vigorously, from which old Mr. Chas. de Breard used to manufacture chocolate. Please desist from condemning the old red variety as delicate, if on enquiry these old trees are found flourishing.—Yours truly MARAVILLA.

[The delicacy is associated with unsuitable conditions of soil chiefly; but the great matter now is to try grafting.—ED. T. A.]

COCONUT BEARING—TREES AND NUTS.

DEAR SIR,—Your *para re* coconut crops in Rajakadalu does not disclose the number of trees from which these 37,000 nuts were plucked.* It is impossible to judge whether the return was satisfactory, good, bad or indifferent, without this very essential item of information.

Is it fair to institute any comparison between Rajakadalu and Kandangomua as to the early bearing capacities of coconut trees? Were the Kandangomua trees that came into bearing so soon, put down by the present proprietor as young plants, or were they trees that had already come into bearing and simply transplanted by him after he bought the property? R.

RED ANTS ON TEA.

Keenagaha Ella, Balangoda, July 25, 1897.

DEAR SIR,—One of my fields is very badly infested with large red ants, some of the tea bushes being full of nests. Can you or any of your readers tell me of any remedy that could be applied to drive them away, as they interfere a good deal both in plucking and pruning.—Yours faithfully, H. H. KIRBY.

[There is a great deal of information interesting to planters scattered through the volumes of our *Tropical Agriculturist* about red ants. One planter welcomed red ants as the “tigers of the insect world” ready to devour all other insects, even white ants! Another complained of his young potatoes at 4,000 feet being all eaten up by red ants. A third in 1882, begged in the interests of morality for a remedy, as his coolies were indulging in awful language in consequence of the numerous red ant nests! But the only remedy we find suggested, is the following and that was for “coffee” not “tea”; however we quote it.—

A CURE FOR RED ANTS.

Dimbula, 23rd April, 1882.

DEAR SIR,—Your correspondent “H. J.” will, I think, find fire a very effective remedy. I once used it on an estate in the Badulla district where there was a patch of coffee that coolies avoided as much as possible: some of the trees had so many as three nests in them. As it was important to destroy the nests without arousing the ants, I tied branches of dry mana grass to long poles, and having sprinkled the grass with kerosine (a very small quantity) placed the fire under each nest in succession. A great many of the

* We fancy the Rajakadalu trees are planted about the usual distance, say 70 to 80 to the acre: the year's crop was 107,000 nuts. We do not know anything of the comparison referred to, and do not in the least desire anything invidious to be fostered. The interest is simply in noting at what age and with what crops, coconut palms come into bearing in different districts.—ED. T. A.

ants were burnt, and those that escaped took care not to come back. Precautions should, of course, be taken against the fire burning anything more than the nests. —Yours faithfully,
B.
[This remedy, if adopted, should certainly be tried only in wet weather.—Ed. T.A.]

RED ANTS ON TEA: A REMEDY. RED ANTS ON CACAO: HOW TO INTRODUCE.

DEAR SIR,—When the coffee trees were infested with Red Ants, I used to apply a few grains of arsenic dropped into their nests from above. In a day or two after getting a dose, they were all dead on the ground and about their nests.

OLD COFFEE PLANTER.

[The above ought to suit Mr. Kirby's case. —How true it is that what is one man's meat (delight) is another man's poison (aversion). A cacao planter in the lowcountry has just been telling us how he welcomes and even introduces red ants to his trees, regarding them —“the tigers of the insect world”—as most useful in clearing away a variety of smaller but more injurious insects. His way of introducing red ants into his fields is ingenious. For a jungle walk he provides himself with a long stick with a piece of meat tied along the end of it: when he wants red ants he thrusts this into a nest, the ants fix in the meat and will not leave it, and finally meat and ants are left on a cacao bush where the insect “tigers” make their future home. Our friend also mentions as a fact within his experience, the great fear of the comparatively big red “tigers” of even one of the small ants so often found in sugar! He has seen a regular “bolt” of the former on one of the latter being dropped in their midst, and he has seen how the little fellow rushes at one of the big ones, fixes immovably on his back and quickly kills him. Can the smaller ants eject a poison with their bite?—Ed. T.A.]

THE RISK OF INTRODUCING RED ANTS ON PLANTATIONS—OF CACAO ESPECIALLY.

Eton, Pundaluoya, Aug. 5.

DEAR SIR,—With reference to the recent correspondence in your columns upon “Red Ants,” I think a note of warning should be given against the too free adoption of the plan recommended by your lowcountry correspondent—who encourages and even introduces red ants on his cacao trees. Although they will undoubtedly destroy many small insects; on the other hand, these so-called “tigers of the insect world” (would not “wolves” be a better simile?) are most distinctly guilty of encouraging the presence of some of our most injurious insect pests. Their relations in connection with “scale-insects” and aphides have often been misunderstood. This same “red ant” was once before largely introduced into the coffee districts by some ingenious individual under the mistaken idea—based upon imperfect observation of its habits—that it would prey upon and finally exterminate the coffee-bug. This was an excellent arrangement for both the ants and the bugs; but the result—from the planter's point of view—was not so satisfactory. Firstly, the coffee was rendered almost unapproachable by the ferocity of these

supposed allies; and secondly, the “bug” increased and waxed fat, if possible, faster than before. “Scale-bugs” and aphides are to the ants what herds of milch cows are to us; and, as such, are tended and cultivated most carefully. In return for the plentiful supply of “honeydew” yielded by their “insect cattle,” the ants will defend them from their natural enemies. I have often noticed that “scale-bugs” attended by ants appear to be in a much healthier and plumper condition than are those which are left to shift for themselves. Colonies of “scale-bugs” and “mealy-bugs” are often included within the nests of the ants; and when the ants outgrow their quarters and migrate to other parts, they carry with them some of their cattle to form the nucleus of fresh herds. If the ants are to be got rid of, after destroying the nests, search should be made upon the neighbouring branches for any “bugs,” and these also destroyed;—otherwise the ants will surely make their way back to the source of attraction.

The fact that the small “sugar-ant” (*Plagiolepis longipes*)—one of the weakest looking of its kind—can attack and overcome the ferocious “red-ant” (*Ecophylla smaragdina*), is a most curious and interesting one,—and rather mysterious too. For the smaller ant is, to all appearance, without any efficient means of offence or defence. Its mandibles are comparatively small and weak, and it is unprovided with a sting. But the fact has been observed more than once. I have been told by one very careful observer, of a regular warfare conducted between the smaller and the larger species, in which the former invariably come off victorious, to the gradual extermination or expulsion of the latter. I have myself seen a large cockroach speedily collapse under the attack of three or four of these weak looking little ants. Possibly these natural enemies might be employed with advantage in ousting the “red ants” from any particular locality where their presence was inconvenient.—Yours truly,
E. E. GREEN.

LACE BARK.

Colombo, July 26.

DEAR SIR,—The June number of the *Indian Agriculturist* has the following reference to the lace-bark tree of Jamaica (*Thymelæwacca*, to which also belong the Sinhalese Naha and Walla—two indigenous fibre trees):—“The tree producing the well-known lace bark of Jamaica is called in that island by the name of lagetto. The inner bark of this tree (the scientific name of which is *Lagetta lintearia*) consists of numerous concentric layers of fibres which interlace in all directions, and thus present a great degree of resemblance to lace. It is said that Charles II received as a present from the Governor of Jamaica, a cravat, frill, and a pair of ruffles made of this material, and it is to this day used for bonnets, collars, and other articles of apparel by Creole ladies.”

I have long been thinking whether the fibre of another tree, belonging to quite a different natural order, viz. Nava (*Sterculia Balanghas*) could not be used in the same way as that of the lace-bark tree. It appears suitable enough for hat-making work, as you will see from the accompanying samples of rough and prepared fibre, and specimens which I have bleached as well as dyed in various colours.—Yours truly,
C. DRIEBERG.

[We shall forward the specimens of fibre to London for report: they look very promising and attractive.—Ed. T.A.]

THE VALUE OF KAJU (CASHEW) NUTS.

Galle, August 2.

Sir,—Kaju nuts being looked upon and classed as fruits of inferiority which grow in jungles, their usefulness and intrinsic worth are lost to the detriment of a good trade. They will contrast favorably with many a fruit tree which adorns gardens and plantations.

If the good uses that are made and can be made of the kaju nuts were more generally known, they would be sure to rest the attention of enterprising agriculturists. How largely have they already taken the place of almonds in the preparation of cakes and a variety of other confectionery. The purity in which these nuts were held by some Civil Servants of old, can be imagined by the fact of their having been frequently applied for from England. Mr. Cripps, the Government Agent of the Southern Province, after leaving the service had an agent in Galle, in the person of the late well-known Mr. Adam de Silva, who at the request of the former sent, I understand, a supply of roasted nuts properly skinned by the monthly mail steamers of the P. & O. Company. The late talented Dr. Sortain of Batticaloa, having doubtless perceived that some medicinal property was to be found in the juice of the fruit, tried some scientific experiment to ascertain its virtue, but with what result I am not aware.

In no other part of the island in which I have been stationed or travelled have I seen kaju trees grow so luxuriantly and to bear so abundantly as in Batticaloa. They appear to grow like mushrooms in some places and within 3 or 3½ years begin to bear. The soil seems peculiarly adapted for its growth.

There are large tracts of land in the vicinity of coconut estates and in other places and Crown lands abandoned as unfertile. All these can profitably be used for the cultivation of the kaju nut, if people can only be made to realise the hidden value that is to be found in the produce of this despised plant.

Large quantities of kaju nuts are annually exported to Jaffna and Badulla, while the latter station sends in as large a supply of gallnuts to Batticaloa, for shipment to other districts. The use and value of gallnuts are sufficiently well-known to need any recommendation to encourage their cultivation, but not so with the kaju nut, as far as my observation will warrant me to speak with any degree of assurance. The day, I think, is not far distant when the kaju tree will rise to assert its superiority over many other indigenous plants of our island. TRAVELLER.

CASHEW-NUT TREE—FRUIT, &c.

August 6.

Sir,—Traveller's letter on Cashew nuts (*Anacardium Occidentale*) is interesting. The kernel of the nuts as he says, is used in many ways. Before the nuts are matured the natives pluck and cut and eat the kernel—the nuts are also roasted and the kernel eaten—but kota cashew (the sun dried nuts) are the most appreciated and deservedly so, as they are delicious and used very largely in the manufacture of cakes and numerous other "sweets." They take the place of almonds and by many they are considered superior to almonds, they are more milky and have not the bitter taste of some almonds.

To the European palate too they are very acceptable, some of the old residents appreciate them very much. It is said that in olden times, a Commander of a Portuguese vessel spent the whole proceeds of the sale of his vessel in the purchase of kota cashew nuts and jaggery, of which he was passionately fond! In the Western Province the cashew trees are getting scarce—the old cinnamon gardens used to be full of them, but they are fast dying out as the cinnamon is being cleared. In the interior the trees are felled for fuel. The process adopted is when a tree is cut down to bury all the wood for a short time, then dig it up and char the branches—the charcoal thus obtained is largely used by blacksmiths and is said to be an excellent substi-

tute for imported coals—the fire kindled being hot and uniform. The secret of cooking a juicy beef steak on a gridiron locally* is the use of cashew nut coals!

TEA PACKING AND BULKING: No. I.

August 5.

Sir,—Many a time and oft have I perused with pleasure the letters of our quondam planting friend John Hamilton, but his latest epistle smacks so much of the Broker, I begin to fear all his old planting instincts have become absorbed or are out of date.

Most Tea Factories worthy of the name employ machine packers nowadays, and with these it is next to impossible to put more tea into a chest than it can comfortably contain.

Final firing is no absolute necessity in a moist climate like this as no matter how airtight our bins may be the teas are apt to lose crispness, during the two or three weeks it usually takes to make up a sufficiently large break to please those London people. Bulking is usually done after, as well as prior to this operation and if done properly there should be no unevenness about it.

That there must be some donkey amongst us however, is evident, or there would never be such a variance as 6 to 8 lb. on the gross weight of a package in any one grade, but why damn the crowd on account of one or two black sheep who could so easily be hung up for public execration by our London friends.—Yours faithfully,

F.

No. II

5th August 1897.

DEAR SIR,—In these days of low prices it will indeed be a serious matter for Ceylon Planters if bulking in London is insisted on by the buyers, and we all owe our thanks to Mr. Hamilton and yourself, for calling attention to the matter.

With reference to his remarks *re* OVERPACKING, it always struck me as a weak point in the advertised recommendations of packing machines that so much MORE TEA could be got into a chest with, than without a packer. And unless a packer was used in the London Warehouse it needs follow that either part of the excess would be left out to swell the "sweepings," or be crushed into the chest by porters' boots, causing complaints of "Dusty and Broken."

As to final firing causing unevenness. If the Tea is slightly rebulked after final firing this need not occur. Mr. H. seems to consider final firing a mistake, but would not tea taste very flat, if nothing more, if sent home without being final fired. That is tea kept for a few weeks in the factory before packing. Packing day by day does not admit of bulking.—Yours faithfully,

BULKING PASSED IN LONDON.

DEAFNESS. An essay describing a really genuine Cure for Deafness. Ringing in Ears, &c., no matter how severe or long-standing, will be sent post free.—Artificial Eardrums and similar appliances entirely superseded. Address THOMAS KEMPE, VICTORIA CHAMBERS, 19, SOUTHAMPTON BUILDINGS, HOLBORN, LONDON.

THE CACAO DISEASE.

July 6.

DEAR SIR,—Mr. E. E. Green in his letter (see page 160) states:—"Mr. v-D-Poorten's argument in favour of the "poochie" theory, is merely that the *dead* wood is full of beetles and that they are often attracted in large quantities by light." Not wishing your readers to have the notion that my intellect is below par, I wish to state that in the letter I wrote to Mr. Green, at his request, on the subject, these were only minor observations and I wonder that he failed to see this. The main one I considered to be the following:—"The 1st sign of the presence of the grub is the weeping of the bark which when shaved, presents only a slightly grey coloration which deepens rapidly, becomes of a claret colour and later dries up. When the ring is not complete the tree survives, if complete but sufficiently high to allow for new shoots, they soon appear and form a new tree or rather bush. I think that when the tree is only partially attacked, the flow of sap kills the grub, but however the vitality of the bark within a regular radius of the puncture is destroyed."—Yours faithfully,

A. VANDER POORTEN.

"MANNA" IN AUSTRALIA.

Technological Museum,

Sydney, July 22nd 1897.

DEAR SIR,—Seeing your note on "Manua" in the June issue of the *Tropical Agriculturist*, p. 828, I have taken the liberty to enclose herewith a copy of my paper on that substance, read before our Royal Society, and hope it may be of interest to you in your Editorial work of that excellent publication.—Yours faithfully,

RICH. T. BAKER.

[The pamphlet referred to is entitled:—

ON THE PRESENCE OF A TRUE MANNA ON A "BLUE GRASS," *ANDROPOGON ANNULATUS*, FORSK.

By R. T. Baker, F.L.S., Assistant Curator and Botanist, Technological Museum, and Henry G. Smith, F.C.S., Chemist, Technological Museum. [With Plates XXI-XXII.] Read before the Royal Society of N. S. Wales, December 2nd, 1896. And the opening paragraph runs:—

The specimens, the subject of this paper, were obtained at Wild's Valley, Torrens Creek, via Towusville, Queensland, by Mr. J. R. Chisholm. They had, previous to our receiving them been determined as *Spumaria alba*, Bull.—a fungus found on grass in this Colony and figured in Cook's Australian Fauna, Pl. 35, fig. 356, but as Mr Chisholm was of opinion that they were galls, he asked if we would also examine them for him. Our first examination showed that they were manna and not a fungus, as we found that they consisted of large quantities of crystals, as well as some sugars.

There are some 17 pages of letterpress including "Chemical investigation" besides the two of plates.—Any one interested can have the loan of this pamphlet.—ED. T.A.]

PLANTING IN HAWAIIAN ISLANDS :

UNDER A FOREIGN V. BRITISH
FLAG.

Ewa Mill, Oahu, Hawaiian Islands, May 31, 1897.

SIR,—I am anxious to acquire some information respecting Ceylon and Coffee Planting. If you have any works bearing on this subject, I should

be glad if you would send me your book catalogue. There are three of us here, who came with the idea of going into coffee raising, but we do not like the political insecurity and should prefer to invest our capital under the British flag.—Yours truly,
CHARLES LENNOX.

[This is refreshing, while Ceylon men are going freely into land for planting, in foreign territory; but then the Dutch who rule in Java and Sumatra, may be said to be good as well as near neighbours.—ED. T.A.]

PLANTING NOTES.

MR. H. L. TEMPLER, who left for Europe recently in the M.M. ss. "Australien," was on his way to Brazil, there to take up the new appointment on the Dumont Company's property which we mentioned some time ago Mr. G. A. Talbot had offered him. He will spend about a month in the old country before going to South America, but will set out from Liverpool for Rio about the end of October, en route for the Province of Paulo; and he expects to take up duties about the middle of November.

CEYLON SUPPLY BASKETS FOR BRAZIL.—Ceylon planters, and Ceylon tea and coffee machinery, are not the only things that other planting countries obtain from this island, for we understand that a well-known Civil Servant has placed a very large order in the hands of a manufacturer for "Supply baskets." They are intended for Brazil, and, as soon as they are ready, will be sent off to their destination. They have been ordered for a coffee estate there, and it is very likely that further orders will follow this shipment.

ORANGE CULTIVATION.—We learn that our informant was not quite correct in the information published by us (see page 210) about orange cultivation. The importation consisted of 15 doz. plants which the Manager of the Ceylon Tea Plantations Company ordered from Australia, and we learn that they have now been planted on 30 estates connected with that Company, from Nuwara Eliya to sea level, and it will be interesting to see where they thrive best. They have been planted more for the benefit of the estate superintendents than anything else, although useful information will doubtless be forthcoming as to their growth.

PLANTING IN PARAGUAY.—The Paraguayans have not found much market for their "Maté" of Paraguay (*Ilex paraguayensis*), the bush from which the South Americans prepare a kind of tea. The Indians collect and dry their leaves, which are ground in mills, those of Parana and St. Catherine, for example, and the powder is packed for transport. According to Dr. Caminhoa, maté is less exciting than tea or coffee, about as stimulating as green tea, and more diuretic than coffee. Some think that mateine, the active principle of maté tea, is the same alkaloid as caffeine, others that it is different because it acts directly on the muscles, whereas caffeine only acts upon them through the nerve centres. Be that as it may, mateine would appear to increase the vital activity in every way; and it does not cause sleeplessness, even when taken in a large quantity. Tobacco is to be cultivated on a larger scale in Paraguay. Several Cubans who paid a visit to Paraguay at the invitation of the Government, go so far as to say that the soil in some parts is almost identical with that of Cuba, which produces the best growth. About a year ago the Government placed two of these Cubans in charge of a plantation near Villa Rica, paying them salaries, and giving them a half share in the profits, besides providing labourers, on the understanding that Cuban methods of cultivation should be employed, and the same taught to such Paraguayans as were willing to learn. The crop raised on this plantation in 1886, though small, is said to be almost equal to the *Vuelta Abajo*, one of the most esteemed tobaccos of Cuba.—*H. & C. Mail*, July 30.

INSECT PESTS—AFFECTING PLANTING
AND AGRICULTURE GENERALLY
IN CEYLON.

“INDIAN MUSEUM NOTES,” VOL. IV.,
No. 2.*

This most useful and interesting serial is still issued periodically from the Museum at Calcutta. The latest part,—Vol. IV., No. 2, contains, amongst other valuable matter, the following articles of more particular interest to agriculturists in Ceylon. The first section describes “an Exhibit Collection of Economic Insects in Indian Museum.” This is a very practical method of giving information on the subject of Insect Pests, and one which might well be imitated in Ceylon. An exhibit of this kind would be a valuable addition to the Museum at Peradeniya, where it would be more available to planters than if placed in Colombo. In the Indian Museum,—

“The insect pests are arranged not in any natural order, but in accordance with the plants which they attack; thus the insects that attack tea and coffee are placed together, then those that attack cereals, and so on.

Wherever necessary, the actual exhibits have been supplemented by enlarged illustrative drawings.”

Amongst the exhibits are several insects with which we are familiar in Ceylon, viz :—*Clania crameri*, the “faggot worm”—common on tea; *Zeuzera coffea*, the coffee borer; and many other old foes. The third part of the report consists of “Notes on Insect Pests,” by Edward Barlow. These also are divided into sections according to the plants affected. Amongst the Tea Pests the first place is given to a description of the moth *Thoesa recta*, the caterpillar of which is frequently reported as doing considerable damage to tea in Ceylon by defoliating the trees.

As this pest is an important one the description may be quoted in full:

“On the 6th May 1895, Mr. E.E. Green of Panduloya Ceylon, forwarded to the Indian Museum specimens of the moth and cocoon of the species *Thoesa recta*, Hampson, also specimens of a Hymenopterous insect belonging to the family Ichneumonidae, said to be parasitic on the caterpillars of the moth, with the information that the caterpillars had proved a serious pest to tea plants in Ceylon. He wrote:—“Mr. W. Holland, of Balangoda, tells me that it has completely defoliated the trees over several acres of tea on his estate, and that the ground is quite black with their droppings. Fortunately a species of *Tachina* preys freely upon them, and eventually reduces their numbers. Mr. Willisford, of Blackwater Estate, sent me specimens, and stated that they had stripped the bushes of everything but the youngest shoots over a field of 50 acres.”

The following particulars are taken from a notice furnished by Mr. E. E. Green:—Larva: Colour bright yellowish green with a quadrate saddle-shaped spot occurring on the middle of the bag; a chain of smaller red spots on the median line in front, and two or three similar spots behind. Oval; convex above, a marginal and two dorsal series of conical spinous tubercles. Cocoon, compact, oval, dull green, fixed to tea leaves or stem.”

[Not a *Tachina*, but a species of Ichneumonid fly.]

I may here take the opportunity of pointing out two rather prominent misprints (or clerical errors on my part). In the description of the larva the large quadrate spot is on the middle of the

back—not bag as printed. And the cocoon of the insect is dull brown, not green as stated. In quoting my remarks the author has appended a footnote contradicting my statement that a species of *Tachina* (a 2-winged fly) preys freely upon and reduces the numbers of the caterpillars. I can only repeat the statement here. The *Tachina* was by far the most prominent of the several insects that attacked the pest. Mr. Barlow was apparently misled by the fact that I at the same time sent him an Ichneumonid fly which also preys upon the insect. The best method of dealing with this pest is to collect and destroy the cocoons, before the emergence of the moths, thus preventing a second and increased brood. The compact oval cocoons will generally be found clustered upon the branches and twigs of the plant. The caterpillars may also be collected; but as they are plentifully armed with urticating spines, this would not prove a pleasant task. If the field attacked should happen to be ready for pruning, the tea might be cut down and the prunings burnt.

The next insect noticed also hails from Ceylon and caused some anxiety at the time of its first appearance. I have not, however, received any recent reports of damage from this pest. It is a small boring beetle (closely allied to the supposed; cause of the present cacao disease) that riddles the stems and branches of tea plants. This account, and the author's remarks, may also be of interest.

* 2:—*XYLEBORUS FORNICATUS*, EICHHOFF.

(Ord. Coleoptera, Fam. Scolytidae.)

Plate V, fig. 2—a, larva; b, pupa; c, d, imagoes ♂ and ♀
e, affected tea stem.

Xyleborus fornicatus, Eichhoff. Berl. Ent. Zeitschr., p. 151 (1868).

On the 28th January 1895, specimens of a small beetle, together with pieces of tea stems riddled by them, were sent to the Indian Museum through Mr. E. E. Green, of Ceylon, from Mr. G. Alston, Superintendent of Tea Estate, Craighead, Nawalapitua.

The insect proved, on examination, to belong to a species of Scolytid beetle, which has not previously been reported to attack tea plants in India. Specimens were therefore forwarded to Mr. W. F. H. Blandford, who very kindly examined them and identified them as belonging to the species *Xyleborus fornicatus*, Eichhoff, a form closely allied to the often destructive species *Xyleborus dispar*, of Europe and North America.

The following is an extract from a letter furnished by Mr. G. Alston:—

“The pest appears mostly in patches, but has spread very considerably since I first observed it in any numbers three years ago. There is no evidence of any previous disease in attacked trees. Most of the trees attacked show no outward sign of the pest, except when almost every branch is attacked, when they turn rather yellow and stop flushing. Young trees about two years old, before they are topped, often snap off at the spot where the borers have made holes for their entrance or exit. Strong vigorous trees in good soil seem to be very little affected by it, and throw out good red wood even from badly bored stems. On the other hand, poor plants on ridges or poor soil seem to naturally feel the effect of it quickly, though in no case have I seen a tree killed by it. Isolated branches die off, but new branches come out in their place. As a rule, you can only tell an attacked tree (except in the case of young plants, when the stems snap off) on pruning it, when the holes in the wood are very apparent. It (the beetle) does not attack the cut surface after pruning, but makes its entrance through the bark. In the case of young red wood it very generally goes straight down the pith: in older branches I have often seen the wood riddled as if a charge of snipe-shot had been fired into it, with only one or two

* Published by Authority of the Government of India, Department of Revenue and Agriculture,

minute holes in the bark for exit or entrance. And yet in the case of vigorous trees, they seem to thrive notwithstanding. Since 1893 the pest has spread very much, and become more general, though I cannot say that I see much difference in the fields that were attacked them."

The writer, in the foregoing account of the pest, practically suggests the remedy—namely,—either not to plant in poor soil, or, if the soil is poor, to improve it, and thus to strengthen the plant against the attack—the great object of all medical treatment everywhere.

To prevent the spread of the disease, the affected branches should be cut off and burnt."

It is unfortunate that the very beautiful figures of the above insect—on plate V—cannot be here reproduced. They are Photo etchings executed at the Survey of India offices, Calcutta, and rival any work of the kind that I have seen in England.

The third article deals with *Carteria decorella*, a coccid insect allied to the species producing the shellac of commerce and the lac-dye. This insect has hitherto been considered a strictly Australian form; but has recently been received from Northern India, where it is reported to have attacked tea. We have two allied species in Ceylon; but neither of them has so far shown any preference for our staple product.

The fourth tea pest is another 'scale-insect,' determined by Mr. Maskell as a variety of *Chionaspis prunicola*. This species has not yet been observed in Ceylon.

The next section is devoted to insects destructive to cereals and other crops. A beetle, *Hispa avenscens*, is reported as having caused great damage to rice crops in India.

"The insects are said to have caused damage to the paddy crop in Poona Taluk, 1,280 acres of land in 10 Amams are reported to have been affected, and the loss is estimated at 20,000 paras of paddy, worth about R10,000."

No remedy is suggested. If this most destructive little insect should appear in any of our paddy fields in Ceylon, prompt measures should be taken to exterminate it before it shall have made headway.

In connection with insect pests of fruit trees, the fact that what the Americans know as "The Red-Scale of Florida"—*Aspidiotus ficus*—is reported as seriously injuring orange and lime trees near Poona, is of some concern to us. This species is already with us, but I have at present found it only upon rhododendron trees in Nuwara Eliya. In the case of the affected citrus trees in India, an application of Kerosene emulsion (strength not stated) is said to have proved effectual in exterminating the pest.

On p. 81 is a reprint of an interesting paper by Mr. R. Newstead—the curator of the Grosvenor Museum, Chester,—upon the agency of birds in the destruction of scale insects. The author finds that the "Blue Tit" and "Long-tailed Tit" devour a considerable number of certain species of Coccidæ in England. Our experience in Ceylon does not lead me to give much credit to birds as aids in the reduction of these particular pests. We have many small insectivorous birds; but they either do not appreciate—or, at any rate, do not make much impression upon the bountiful feast provided in a field of bug-infested coffee. They certainly frequent such coffee; but chiefly to feed upon the flies and other insects attracted by the sweet secretion ("honey-dew") from the scale-insects. It is possible that the "green-bug," *Laccanum viride*, may have developed distasteful qualities that make it unpalatable; or that,

being (as I believe) an introduced species, the native birds do not recognize it as an article of diet. The more local species of scale insects may partly owe their comparative rarity to the attacks of our insectivorous birds.

Altogether this periodical publication from the Indian Museum more than maintains the high standard of interest with which it commenced some seven years ago.

E. ERNEST GREEN.

A NEW SCHEME FOR CYPRUS.

Professor Patrick Geddes of Edinburgh and Dundee is no ordinary man. By many of his admirers he is considered an extraordinary genius and he certainly never fails to impress all with whom he comes in contact with his own views. The result is that he has carried out some notable schemes in his day. Almost single-handed he started and carried on University Extension Summer Meetings in Scotland. He has been instrumental in rebuilding a great part of High Street, Edinburgh, beautiful and stately houses taking the place of squalid tenements. He has long been interested in the countries bordering on the Mediterranean and attributes the decline of ancient Rome with modern Spain, Turkey and the Ægean to the gradual deterioration of their soil—chiefly due to the cutting down of trees. This he thinks has altered both soil and climate; and he is very strong now on the mischief which has similarly been wrought in Cyprus. He has been writing in the *Contemporary* as well as in London weeklies on a scheme he now has for resuscitating Cyprus. This must be found in afforestation,—“a holy war” Mr. Geddes calls it which may last a long time, but which as it goes on will bring back wealth, health and happiness to the impoverished and degenerate Eastern races. But the Professor does not simply preach about afforesting and irrigating; he takes action himself. He is forming a Company to take over two estates in Cyprus already purchased by him; and he has secured Mr. Chamberlain's promise to ask for a grant of £60,000 to be applied to irrigation in the island. Professor Geddes considers Cyprus to be both healthy and safe for British residents: no one has had fever or been molested for 18 years back. The island is also a great centre for the South-East of Europe and when his Company has its farms, fruit gardens, its trees, springs and wells, in flourishing order, there will be a profitable trade outlet available both locally and for export. We feel sure that Professor Geddes will have the good wishes of all who hear of his scheme for the restoration of prosperity to Cyprus—an island of whose scenery and highland people he speaks in most favourable terms.

PLANTING IN PERAK AND SELANGOR.—We have called a good deal of interesting information from the Annual Reports of the several District Officers just published, which will be found reproduced on page 191. Coffee, tapioca, coconuts, pepper and sugar are the products dealt with in Matang of Perak.—Planting in Kuala Langat, Selangor, by Europeans, does not seem to prosper.—But we have Ulu Langat district with a very sanguine account of the future in Liberian coffee, for which a large area of land has been taken up.—Finally, there is Ulu Selangor district where coffee-planting under both European and native auspices, is in progress.

COFFEE NOTES.

In 1895 France imported 142,156,372 kilos of coffee, of which 56,734,903 were from Brazil.

A company of Americans has recently purchased 60,000 acres of coffee, on the Rio Tinto, in the state of Oaxaca, Mexico, and will colonize the tract with several hundred American families.

Experiments have been recently made with hot talc for drying coffee, and excellent results are reported. It is stated that freshly gathered coffee, can be dried in this way in four hours and that the article thus prepared is superior in aroma color and weight to coffee prepared by other processes.—*The Rio News*, July 6.

A SUBSTITUTE FOR COFFEE.

Consul Deuster, under date of April 8, writes from Crefeld :

Believing that it will prove of interest to the malt-coffee manufacturers of the United States, I submit the following report for publication :

Under the firm name of Katheriner's Malz-Kaffee-Fabriken, factories have been established in Germany—of which one exists in this consular district, at Merdingen-on-the-Rhine, and others at Munich and Berlin—for the purpose of manufacturing a coffee substitute from cereals. The invention relates to an improvement in preparing the same, which consists in applying to the grain during the steeping process, an electric current proportionate to the quantity and quality of the grain whereby the proteid substances existing in the grain are altered in such a manner that, in the subsequent roasting process, only a small quantity of the products of decomposition (as pyridine and its derivatives which are objectionable to the taste) can be formed, a substitute pleasant to the taste being obtained.

Under this patent, factories have also been established in Austria, Italy, France, Switzerland and Sweden. The inventor has also applied for a patent in the United States.—*American Grocer*, July 7.

NEWS ITEMS.

(From the *Chemist and Druggist*, July 24.)

THE PERFUMERY-TRADE OF NICE.—The manufacture of perfumery goods in Nice is on the increase. In 1896 1,420 cwt., worth 10,634*l.*, was exported; the year before 1,120 cwt., worth 8,492*l.*

PARAGUAYAN OIL OF PETITGRAIN.—There has lately been an increase in the shipments of petitgrain oil from Paraguay. The oil is exported chiefly to France. The principal seat of the industry in Paraguay is at Yaguaron, a village about twelve miles from the railway.

ARMOUR'S PEPSIN-FACTORY BURNED.—The *Practical Druggist* reports the destruction of Armour & Co.'s new pepsin factory at Chicago by fire. A terrific explosion was heard in the factory, and almost before the alarm could be sounded the big six-storey building was in flames. Every available engine in the city was set to the fire, which is in the centre of the stock-yards district, and the fire was checked after it had completely destroyed the factory. The building was only completed in May, and the machinery was moved into it ten days before the fire. The explosion which started the fire was in the chemical store room. The damage done is about \$75,000.

RINDERPEST IN SOUTH AFRICA.—It is reported from Cape Town that satisfactory experiments have been made with the new method of inoculation discovered by Dr. Edington.

THE ENGLISH DRUG-CROPS.

Only a few weeks still separate us from the season when the English peppermint and lavender plants will be put in the still. According to our custom, we have asked some of the principal growers to give

us their opinions of the state of the crops and submit some of the replies received:—

Messrs. W. J. Bush & Co. (Limited) say: "We think we are justified in anticipating very good crops both of Mitcham peppermint and lavender oils, especially of the former. It is true that the young cuttings which were planted last autumn suffered severely from the excessive rains, and a large number of them 'damped off' and were lost; but as the weather in the early spring was so very favourable for mint-growing, we know that several farmers planted more cuttings, which have done remarkably well, and, in fact, look as strong and healthy as those which survived the bad weather of the autumn. We are sanguine, therefore, of a good crop, and although the acreage is slightly smaller than last year, we think that the deficiency will be made up by a good yield of oil. So far as lavender is concerned, we believe a good crop will also be obtained. The fields look very healthy, and the farmers are getting over the loss of plants which they sustained by the severe weather of some years ago."

Messrs. John Jackson & Co. report: "Our plantations of mint, lavender, chamomile, and rosemary are this year of a most promising appearance, and lead us to expect fine crops. Mints are gratifying to look at, especially the white sorts, which have now become fully developed in most of our fields. In the early part of June both black and white mints were thin and undeveloped, but since then the rain-storms, followed by sunny days and high temperature, have changed the appearance of the vegetation within a few days, and by the end of June the plants were fully expanded, and had taken such a vigorous start that they were covering the soil so thickly and uniformly as to prevent the air circulating round the stems. As a result the lower leaves soon turned yellow and withered, and they may, if we judge from appearance get dry and fall before ripening, thus impairing the coming crop (should this damage become general), as no remedy could possibly avail. Our lavender-plantations are, as a whole very fine, and promise a fair crop. Should this expectation be realised, we may be induced to lower our prices, which for some years past have been kept high, thus causing foreign inferior oils to come in to the market in preference to our higher-grade Mitcham lavender oils. Rosemary is also in a very satisfactory condition, and will, we trust, give us full satisfaction. The chamomile-plants have grown with abnormal vigour, and the first flowers seem generally very small. We fear, therefore, that the undue development of the leaf may lessen the yield of the flowers."

Messrs. J. & R. V. Matthw Brothers say that the peppermint-fields look fairly well, but will not yield a heavy crop if the present dry weather should continue. Lavender is a very indifferent crop, owing to blight; appearances indicate a light yield. Chamomiles look well. Messrs. Matthw Brothers add that these observations refer to their own growth only.

Messrs. W. Ransom & Son, of Hitchin say:—"The prospects of our crops, with one important exception, are fairly good. Henbane, however, is shorter than we have known it for many years, and the prices of extract and leaf ought to be much higher than they are. The belladonna-crop is about equal to last year's. Lavender and peppermint both look well at present, but much will depend upon the weather during the next few weeks. Aconite is abundant; but the prospects for elaterium are hardly up to the average."

It will be seen that our informants, with the exception of Messrs. Matthew Brothers, are unanimous in their anticipation of good crops for the leading essential-oil plants. The Messrs. Matthew's views are in peculiar contrast to those of the other growers and we must say that our own general observations lead us to draw the same conclusions as the majority of our correspondents. But the Messrs. Matthew, it will be seen, expressly state that their statements refer to their own fields only.—*Chemist and Druggist*, July 17.

TEA MACHINERY FOR JAVA.

We understand that Mr. J. H. S. Davidson, nephew of Mr. S. C. Davidson, the inventor of the well-known "Sirocco" Machinery leaves, by the P. & G. steamer "Rosetta" on Saturday next, Aug. 3 for Java in order to superintend the erection of extensive orders for Sirocco Tea Machinery including a number of the newly patented automatic dryers, which machines have proved themselves unequalled in India during the past season. One factory alone about to be fitted will require machinery for 2,000,000 lb. per annum. On one Indian estate alone this new machine dried over 700,000 lb. tea last year, which on the London market averaged $\frac{3}{4}$ d more than teas dried by other large tea dryers. Mr. Davidson will also take charge of the erection of a number of Davidson's Patent Rollers, Oxidizers, Downdraft and Updraft Siroccos, Sorters, Packers, etc., numerous orders for all of which machines have been booked for that Island. Mr. J. H. S. Davidson has been a practical planter and engineer for over 8 years, and he will no doubt be able to give a lot of assistance to Java planters.—Local "Times."

ORANGE CULTURE IN CEYLON.

An upcountry planter sends us a copy of the local "Times," marked at an editorial paragraph on "Orange Culture" with notes as appended:—

As a result of the attention drawn to the matter, some planters from upcountry ordered a number of orange plants through a Colombo store-keeper from Melbourne.* The parcel of plants duly arrived here by the last P. & O. steamer in a very healthy condition, and they were despatched in lots on Thursday night by the rail to Veyangola, Nawalapitiya, Talavakelle, and to a few other places upcountry. We understand that the plants are very choice ones and were selected from a special nursery, and that they cost very nearly £500 laid down at Colombo. They were securely packed in small bags, with the nursery soil, and looked quite fresh and green, but without a single leaf. They promise to do very well, and we shall be glad to know results of their successful cultivation upcountry. The native orange (by the way, is it indigenous?) like other native products, is not systematically cultivated by the Sinhalese. It is generally believed that oranges grown on the hills are not so palatable as those grown in the lowcountry, and that the Salpiti Korale, Kotte, and the neighbouring villages, produce the best oranges, as the soil there is best suited for their culture. Upcountry, we are told, the plants thrive well, but the oranges do not taste so well as those grown in the lowcountry, though Nuwara Eliya and the Uva Province produce fairly good specimens.† Of course, the oranges grown in Ceylon and India are quite unlike those from Australia and the West our oranges, however ripe they may be, as a rule preserve their verdant hue and do not take on a yellow one, while the taste is a sharper and more refreshing one than the sweet flavour of the oranges met with in Europe. We understand that a large quantity of oranges are imported into Australia during the summer from Italy and Spain, and there is a growing demand for them in the Colonies. Should therefore the experiments now being made upcountry prove a success, there should be no reason why Ceylon should not compete in the Colonies with Spain and Italy.‡ It

* Not supplied to C. T. P. Co.'s superintendents for private use.—Cor.

† None in N. Eliya and Uva oranges are the worst in Ceylon.—Cor.

‡ Meanwhile the Colonies are supplying us not only with oranges but with plants!—Cor.

is a pity that a few lemon plants were not imported as well. The Australian lemons are simply exquisite, and they have a much finer flavour than our Ceylon limes. There is every reason to believe that lemons could be cultivated in our Island as well as oranges.

[The original habitat of the Orange is Northern India whence it spread West, East and South. Some species of lime and orange were introduced here from the Malay Archipelago.—ED. T.A.]

DRUG REPORT.

(From the Chemist and Druggist.)

London, Aug. 12th.

CARDAMOMS.—An Indian correspondent writes: "A very good business was formerly done between Ceylon with Bombay in cardamoms, but the Plague put an end to it, and transferred the trade from Bombay to Calcutta. The principal buyers at that place are the chetties, and a smart business has been done between them and the native merchants during the last two months, in both Malabar and Mysore cardamoms. About 3 rs. per lb. was paid in June for Mysore, and native merchants were very eager to make advances on crops on estates. But since then there has been a sudden fall in price, and the chetties will not touch the produce now. Very few of their shipments realised any profit at all, and they are now repenting of the high prices they paid for the drug. Large stocks of Mysore cardamoms are held by the native merchants, and, with the influx of the season's new crops, it is believed there will be a further drop in prices." In London the market is firm, but there is a disinclination to pay the advance asked by owners who have bought at auction.

CINCHONA.—A parcel of fifty-five bales Maracaibo bark has arrived and will be offered at next Thursday's auctions when a lot of 25 packages newly arrived Guayaquil Crown bark will also be offered for sale.

COCOA-BUTTER.—At auction on Tuesday 300 2-cwt. cases of Cadbury's best cocoa butter sold with little competition at a decline of $\frac{3}{4}$ d to $\frac{1}{2}$ d per lb.—viz. 11 $\frac{1}{4}$ d to 10 $\frac{3}{4}$ d per lb.; 205 cases Dutch cocoa-butter were bought in at 10 $\frac{1}{4}$ d to 10 $\frac{1}{2}$ d per lb.

OILS (Essential).—The quotations from the East are higher. Oil of Citronella is altered Lemongrass held for 2 $\frac{3}{4}$ d per oz. on the spot. To arrive no business is reported.

QUININE.—Several small sales, aggregating about 5,000 oz. were made early in the week at 9 $\frac{1}{2}$ d per oz., for fair second-hand German bulk, showing a firm market. The price of the Auerbach brand has been raised to 10d per oz.; other foreign agents have no definite prices, although Brunswick quinine was erroneously reported in one quarter to have been raised to 10d per oz. Early in the week the B. & S. agents sold two 1,000-oz. lots to druggists at 9d per oz., but since then they have stopped offering. They refused to deal with any but druggists, or to sell more than 1,000 oz. to any one firm. On Saturday a Mining Lane broker went around trying to buy 5,000 oz. at 8 $\frac{1}{2}$ d, but he appears to have been unsuccessful. Howard's price is unaltered, but Whiffen's is reported to have been raised. Sulphate of cinchonidine has lately been in strong demand for India, and is quoted higher.

TONCA BEANS remain extremely quiet, and no business has been reported lately. Good bright Angostura are quoted at 7s to 8s per lb.; good frosted Para at from 1s 7d to 1s 10d; fair black, partly foxy mixed at from 1s down to 5d per lb.

THE DUTY ON COCOA-BUTTER.—In reply to Sir Howard Vincent, the Chancellor of the Exchequer has given some information as to operation of the duty on cocoa-butter. The revenue obtained by the duty has amounted to 3,004L. from August 7th, 1896, the date on which the duty took effect, to June 30th, 1897. There are no statistics of the importation of cocoa-butter prior to the imposition of the duty, but, so far as can be ascertained by inquiry of the trade, the quantity of foreign cocoa-butter has increased rather than diminished. This is probably due to the fact that the business in cocoa and chocolate has been very active during the past eight months.—*Chemist and Druggist*, July 17.

THE AGRICULTURAL MAGAZINE, COLOMBO.

Vol. IX.]

SEPTEMBER, 1897.

[No. 3.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for September:—

SEASON REPORTS.

WESTERN Province.—Paddy. Yala crop thriving, preparations for Maha going on in some places. Fruits and vegetables plentiful in Colombo district and Rayigam

Korale. Rainfall sufficient.

Central Province.—Paddy. Maha cultivation begun; rainfall at Matale 3·38 in.; a case of alleged murrain reported from Matale South. A good supply of fruits and vegetables in Nuwara Eliya.

Northern Province.—Paddy. The threshing of the Kalapokam paddy crop is nearly over every where; where Sirupokam paddy was sown the crop is about to be harvested. No rain in Jaffna and Mannar districts, but few showers in Mullaittivu.

Southern Province.—Paddy. Yala crop in course of being harvested. Rainfall in Galle 5·26 in.

Eastern Province.—Paddy. Pinnari cultivation somewhat interrupted by rain and flood in Batticaloa, in Trincomalee satisfactory and promises well. Cattle murrain still lingers in some villages, but is being stamped out. Rainfall, ·51 in Batticaloa, and ·95 in Trincomalee.

North-Western Province.—Paddy. Crops in various stages, but good yields are expected; no murrain except in Hiriyala Hatpattu. Rainfall at Puttalam ·69 in.

North-Central Province.—Paddy. Crop nearing harvest and prospects good. No cattle murrain. Rainfall at Anuradhapura ·10 in.

Province of Uva.—Paddy. Maha harvest over, yield good. Vegetables scarce and dear. Health of cattle good.

Province of Sabaragamuwa.—Paddy. Yala crop prospects good. No reports of cattle murrain. Rainfall at Ruanwella 8·63 in., same in Ambanpitiya.

THE LABOUR QUESTION.

The Labour difficulty in Ceylon cannot be expected to decrease with the increase of plantations. The formation of large companies of late years, and the opening up of extensive tracts of land in the Balangoda district by Messrs. Finlay, Muir, & Co. chiefly, have created a great demand for large gangs of coolies. And as all the required fresh labouring hands are not brought over from

the coast, the home of the immigrant labourer, it follows that the required forces are in great measure drafted from the already existing plantations. No great foresight is therefore needed to prophecy that the simple plan of taking from Paul to pay Peter, or from Peter to pay Paul is not conducive to their mutual benefit.

In the meantime, as the shifting of labour is the direct result of immediate or prospective gain to the labourers, advances on coolies have gone on increasing all over the Island. To what extent advances have already risen is shown in the evidence afforded in the late desertion case of Rowlands *vs.* Valliamma. It appears that the sum of R274.50 was not considered too high for two women and one boy. And this brings us once again to

THE LAW OF CONTRACTS.

It is unfortunate that Superintendents do not regard in all its gravity the requirement that the contract of hire and service is one that should be entered into directly with the labourer and not with the kangani.

It is often the case that negotiations are carried on entirely with the kangani who offers to place the labourers on the estate upon the payment of a certain sum of money, which is called an advance.

In the case under consideration, the advance per head amounts to as much as R91.50, a sum considered high for Ceylon even by Mr. Justice Withers. The Superintendent, Mr. Rowlands, naturally thought that all things and conditions were done and fulfilled by him to entitle him to consider that the labourers who found their way to his estate, were to all legal intents and purposes his servants. If the entry of the servant's name on the check roll, the occupation by them of rooms in the lines, and the receipt of a few measures of rice were elements that sufficed to support an implied contract, how much more would not the payment of so large a sum of money to save the cooly from his persecuting creditors, the Chetty dealer and the Moorman trader, afford confirmatory proof of a contract between the labourer and the Superintendent,—so at least must have thought the Superintendent.

But the Court held that there was no contract proved between the parties to support the charge of desertion. It cannot be too often repeated that the requirements of the Labour Ordinance should be strictly adhered to by the employer before he could claim the benefit of its provisions, so as to bring an offender before a summary Court of Justice as a criminal.

The subject of advances to coolies is one that has engaged, no doubt, the best attention of the foremost planters in the Planters' Association, among whom too are men of legal attainments, and it has more than once been recommended to the Planting community by those best able to foresee difficulties, that advances should be made to the labourer direct and not to the kanganies.

The usages and customs between planters and coolies which obtained in the past, and were regarded as a sort of unwritten or common law have gradually come to the ground, and in the present day the planter who relies on these usages reckons very frequently without his host.

It has been contended that this is not a practical suggestion. It may or may not be so; but now that advances are going up gradually to three figures per head it would not be out of place to state that whatever may be the conveniences afforded by the system of making advances in a lump sum into the hands of the kangani to enable him to pay the debts due by his gang, or by cheque to the employer who sends out his "tundu," it would be well for the Planting community to consider whether they should not introduce a rule, that in all cases new coolies should be individually seen by the Superintendent upon their arrival, and whenever it is practicable that the advances should be ascertained as separate debts and placed against each man and woman as stated or acknowledged. Such acknowledgment by cooly and entry by Superintendent cannot fail to be of service to the Superintendent in Court.

And if such a system had been in vogue among planters, the case under review could not possibly have failed from a want of evidence of the contract to serve, since to acknowledge the receipt of the advance parties had to meet face to face as master and servant.

In the case of Rowlands *vs.* Valliamma the Superintendent has not only failed in the case of desertion, but stands a slender chance of recovering his advances from the three coolies to whom he granted a "tundu."

OCCASIONAL NOTES.

The two varieties of paddy seed received from the Agricultural Department of Madras some time ago were sown in the School of Agriculture grounds last sowing season and the crops are now coming into ear. We owe our thanks to the Director of Land Records and Agriculture of the North-Western Province of India, for three varieties of paddy received from Cawnpore. The seed paddy we have been so fortunate as to secure was sent on our application for the best approved varieties. Some of this seed will be grown at the School of Agriculture and the rest in the Matala district.

We make no apology for publishing in full the Report of the Superintendent of the School of Agriculture on the working of the several establishments under his charge during last year. Few of the public have the opportunity of reading the Administration Reports of heads of departments, and we have no doubt that there are many who will be glad to note the progress made by the dairy, and to be provided with the financial details of the concern. Owing to the publication of this report a good deal of other matter has to stand over.

The Colonial Veterinary Surgeon thus refers in his report for last year to the "obscure disease" more than once written about in the pages of the Magazine, and once treated of under the head of "Hepatitis":—During the year several cows appeared to be slightly unwell at intervals and to change colour gradually, principally white cows. The first thing noticed about

them was that they panted a little during the heat of the day, and for this laxatives and saline febrifuges were administered. In two or three weeks, on closely examining the skin, bluish hairs could be detected mixed with the white. This gradually advanced until the colour of the animal was a distinct bluish gray. In a few weeks more the shade gradually changed to brown, finally developing into dark brown. At the same time the hair grew very long, making the animal appear to have developed a thick winter coat. The skin itself also tends to become darker in colour. In connection with this change in colour the animals very gradually became thinner, appearing to grow smaller in size, and gradually ceased milking (if a milk cow). In all other ways there was nothing to be noticed, so that a stranger would not observe anything wrong. I did not have an opportunity of a post-mortem examination, as there were no deaths. I have noticed on one or two occasions odd cases at the public sales in Colombo exactly similar to those I have described, but as far as I have been able to learn it was not recognized as a disease. Professor Wallace, the eminent Agriculturist, saw these cases when in Ceylon and suggested liver disease. I was convinced the change was of a pathological nature. Consequently, I sent a photograph of one animal and specimens of its hair to the Royal Veterinary College, London, to an eminent pathologist, whose reply was as follows:—"The cases to which you refer are certainly remarkable, if the change in colour of the skin and hair is really pathological. I never heard of such a thing, and am quite at a loss to account for it.... I shall be glad if you will let me know what the further progress of the cases was, and whether you have observed any other cases of the same sort since you wrote." I may mention that all the cases I saw were imported animals. I am unable to give a definite opinion upon the nature of the change, but my impression is that it is due to morbid change of the blood glands of the liver, due to the changed mode of life and feeding upon rich food. In one case, a white Coast cow, the change in colour developed in patches, which gradually became larger and confluent.

We acknowledge with thanks the receipt of five copies of a pamphlet containing Dr. Koch's reports on experiments conducted by him for the discovery of a cure and a prophylactic for rinderpest, sent to us by Vet. Major Mills, Principal of the Bombay Veterinary College. These reports were published in the pages of the Magazine from time to time, but as now presented they form a handy little book of reference. The pamphlet is published with the sanction of the Government of India.

FRUIT CULTURE.

The physiological facts referred to in our last issue are what all successful tree culture is founded on, whether the workman knows and

intelligently applies them, or whether he follows empirical rules that have been taught him without explanation of the reason for them. They show that compact un-aerated ground, which has never been mixed up with its own bulk of air by trenching to something more than the depth to which average roots penetrate, is not fit to grow trees. They show that the unfitness is only locally and partially rectified by digging out a two or three foot hole and making its earth contents as loose, aerated and open as the whole orchard ought to be. They show that when the advancing root system of the trees has got beyond the poor thirsty dozen cubic feet of decent soil in its hole it reaches the compact earth walls around it and progress is barred. If the feeding tips force their way in, there is little or no air, and they cease to respire freely. If they coil back upon the loose earth in the hole, they find it impoverished, for it is their leavings of former years. Of course the trees' demands are just as great as ever, but the stifled rootlets in the hard untrenched soil and the famished ones in the hole space cannot supply them. Then follows a lingering period of death, more or less drawn out according to circumstances. The young wood of the year dies back, making the well-known appearance that gardeners have likened to stag's horns. This fatal error of insufficiently trenching up land meant for orchard purposes and relying on the contents of small artificial pits is one of the reasons why fruit trees that do not get fair play are so shortlived.

Again, in watering, what do we do? We pour it on the depression round the tree till the hollow is full and bubbles of air keep coming up in the pond that has been formed. Where are the air spaces which we saw were so essential for the vitality of the roots? Why, every bubble of vital air has been drowned out and forced to ascend and escape at the surface. What should be full of air is now full of water. The roots are completely immersed and their respiration is stopped. Fortunately this state of things does not last long. Even the most compact-clays slowly absorb water, and the destructive surplus percolates away through their substance, relieving the asphyxiated roots and making way for air to enter from the surface. The repetition of this drowning process several times a week is a common cause of the dropping of fruit, the dying out of the special young shoots of the year, and the general short space of life allotted to a neglected orchard on any other than a sandy open soil.

Successful culture depends upon the degree of completeness with which we can make our soil resemble the mechanical condition present in a sponge. We must recognise that trees do not grow in earth alone, but in a mixture of earth, air and water. That mixture is *soil*, if the word is properly understood. Our endeavour should therefore be to bring earth into the condition of soil, for between the two there is something of the difference that exists between the rudest barbarism and a high civilization. Little or nothing is possible to the former, but everything is possible to the latter.

NOTE ON GREVILLEA.

Grevillea robusta, which makes such a useful and ornamental windbreak in our tea plantations, has been ascertained to draw from its soil for nourishment so little of the properties demanded by the tea, that its presence is rather an advantage than otherwise in the opinion of many planters even as regards the yield of the bushes round about them; but one curious feature has been noted in places where occasionally a *Grevillea* dies out, and that is that the tea in the neighbourhood of its roots dies out also. It is impossible to account for this phenomenon without a careful examination of the roots of the *Grevillea*. A few years back a mycelium which affected patches of *cocca* in the West Indies was traced by the Director of the Botanic Gardens, Leeward Islands, (Mr. C. A. Barber) to the dead stumps in the ground which started the root fungus that spread so rapidly and with such disastrous effects to the *cocoa*.

Whatever may be the causes leading to the destruction of the tea at the foot of the dying *Grevilleas*, it would not be amiss in all cases to have the roots of the latter taken off the ground as far as it is possible along with the dead stumps occurring in tea fields.

REPORT OF MR. C. DRIEBERG, B.A., F.H.A.S.,
SUPERINTENDENT OF THE COLOMBO
SCHOOL OF AGRICULTURE.

THE SCHOOL.

The number of students in the school has never been allowed to exceed twenty-five at any time, as the dieting vote does not permit of a larger number being provided for. As a rule, however, applications for admission have been in excess of our requirements, but in 1896 the applicants were few, and when the usual examination test for admission came to be applied, it was found that there were less than a dozen eligible students. The falling off is attributable to certain alterations in the conditions that attach to studentship at the school, made by the then Acting Director, as well as to the fact that the boarding fees were raised. But the reversion to the old order of things will, I expect, in spite of the higher boarding fee, give to the school its full complement of students next year. As yet no separate vote has been allowed for special agricultural work in connection with the school, but in spite of so serious a drawback some work of this nature was done. A cheap and light type of plough (weighing about 25 lbs.) was designed and constructed, and serves its purpose well. Trials were made with blood manure as prepared in Colombo, and "Homco," a vegetable manure meal manufactured from rape and other oil seeds by the Hull Oil Company. The makers kindly placed a ton of the latter at my disposal free of all cost, and I am glad to be able to report for their satisfaction that "Homco" has given excellent results with garden crops and acted more quickly than blood. The manure is also being tried on coconuts and other planting products in various parts of the Island, but it is yet too early to judge of the results of these trials, though so

far reports received have been favourable. The following is an analysis of "Homco," as supplied to me, by Dr. Bernard Dyer:--

Moisture (loss at 212° F.)	11.82
Organic matter*	80.58
Phosphoric acid†	2.36
Lime	1.02
Magnesia, alkalies, carbonic acid, &c.	2.27
Insoluble silicious matter	1.95
Total...			10 000

* Containing nitrogen

Equal to ammonia

† Equal to tribasic phosphate of lime

The Company guarantee 6½ per cent. of ammonia and less than 3 per cent. sand. The price of "Homco," guaranteed to contain from 6¼ to 7 per cent. ammonia, in double bags, free on board, London, is quoted at £3. 5s. per ton.

The vine experiments had unfortunately to be abandoned, much to the disappointment of many interested in the venture, as satisfactory arrangements between Government and Mr. Zanetti, the viticulturist, could not have been made for its continuance. The experiment, while it lasted, was decidedly promising, and went to prove that, under suitable conditions and intelligent management, the "extensive" system of grape cultivation, according to continental methods, ought to be a success in Ceylon. As a result of the experiment a few landowners have begun growing vines on their own account, while it is satisfactory to know that about a thousand vines of the finest cultivated varieties have, by sale, been distributed throughout the Island. It is to be regretted that the experiments could not have been kept up at the school till the vines had reached the full-bearing period.

I am daily expecting half a ton of "Jadoo fibre" which the manufacturers are sending me free of cost from Exeter. This growing medium has been brought prominently to the notice of the agricultural public, and I am most anxious to give it a fair trial. It has already been highly spoken of as being of the greatest service in "supplying" tea plants in nurseries, in propagating by cuttings, and especially in pot-culture.

I have also been in communication with the manufacturers of "Natrugin" in Höchst-on-the-Main and hope before long to be in a position to say, whether pure cultivation bacteria for leguminous crops are likely to be of practical value in the agriculture of the Island.

As in former years, a large number of inquiries were received and answered, while such seeds and plants as were available for distribution were supplied to those who applied for them.

It is to be hoped that before long the School of Agriculture will be placed on an independent footing, so that its interest may be specially cared for and not sunk in the general interests of a complex establishment of which it is now but an unit—without a proper status, scheme, or vote of its own, and without the means of fulfilling the true functions of an agricultural school.

During the year the Government dispensed with the services of the agricultural instructors, as it was thought that the results of the work of these officers were not sufficiently fruitful to warrant

their retention. An exception was however made in the case of the instructor at Balangoda (Mr. H. D. Gnnasekara), who at the special request of the Government Agent of the Province of Sabaragamuwa was kept on. This officer, who has a good record of work to show, is at present engaged in establishing an experimental farm at Mahawalatenne, where the cultivation of economic and medicinal plants as well as the breeding of cattle and poultry will receive attention. The experiment should prove an interesting one, and with the liberal help of the Ratemabatmaya (Mr. C. D. Mahawalatenne), and the patronage of the Government Agent, should not fail for want of support or for lack of enthusiasm on the part of the instructor.

On the discontinuance of the agricultural instructors I forwarded the annexed report to Government, submitting suggestions for re-organizing and better equipping the school and for carrying on its work on more practical lines.

It is a difficult matter to show the exact expenditure on the School of Agriculture as distinct from the expenditure on the other schools located in the same building, and this fact has led to incorrect estimates of the actual cost of the school to Government. But making as fair a calculation as possible, the cost of the School of Agriculture does not exceed Rs. 6,000 per annum.

The "Agricultural Magazine" in a slightly enlarged form is still kept up: it is now in its eighth year, and is, I venture to think, of good report. Though the work of editing is rather a tax on my time, the magazine has proved of great service to me as a medium of communication with other countries, where it has been accepted in exchange for agricultural publications which I would otherwise have no opportunity of seeing. I am glad to state that the Government has allowed a bonus of Rs. 150 per annum for the publication of the magazine, and I should here wish to record my gratitude for the concession. My thanks are specially due to the Indian and Tasmanian Governments for their liberality in supplying me with their valuable reports and bulletins free of cost.

THE SCHOOL OF FORESTRY.

This school started work on the 15th of April with six students (a limited number), three of whom were drafted from the Forest Department, and the remaining three selected from the students of the School of Agriculture after competitive examination. The following is a list of the subjects taught, with the names of the teachers annexed:—

Forestry	...Mr. Broun, Conservator of Forests.
Mathematics	...Mr. Walter Parys.
Forest Law	...Mr. F. M. de Saram, Advocate.
Surveying	...Mr. Dyson Blair.
Botany	...Mr. C. Drieberg, Superintendent, School of Agriculture.

The course of training as at present arranged covers one year. During the latter part of the year the students were taken on tour by the Conservator of Forests himself. The tour occupied about six weeks, during which period many of the forests of the North-Western and Central Provinces that lie on the route between Kurnnegala, Dambulla, and Matale were traversed, while visits were also paid to the Galboda, Nanu-oya, and Nuwara Eliya plantations. The six students who will be the

first trained in the Forestry School are Messrs. Jansz, Jayman and Galagoda of the Forest Department, and Messrs. Fernando, Mendis, and Ratnayaka from the School of Agriculture.

THE TRAINING SCHOOL.

The number of students trained at one time in this school was, until 1896, ten; but during the year this number was reduced to five as the result of the opening of a training school in Peradeniya, which was intended specially for the training of Kandyan teachers for Government vernacular schools in the Central Province.

THE PRACTISING SCHOOL.

The Practising School, conducted in connection with the Training School, has about 80 boys on the roll and an average attendance of about 50. The school is a purely vernacular day school. Situated as it is in the metropolis in a more or less remote suburb, it is not taken advantage of as much as it would be if it were an Anglo-vernacular institution. The demand for an English education is naturally keen in the neighbourhood of Colombo, and native parents of the poorer class are satisfied with a IVth or Vth Standard vernacular education for their sons, who are then given the finish in English which qualifies them for the higher grade appointments as domestic or office servants. For this reason the highest standard that can at present be maintained in the school is, much to the disadvantage of the training students, the Vth.

THE GOVERNMENT DAIRY.

All things considered, the dairy has had a fairly good year. I have endeavoured to curtail my report on this institution by arranging facts and figures in tabular form. Statement A. is a return of the stock. The dairy was free from any form epidemic, but, as will be seen from the return furnished, a comparatively large number of calves was lost during the twelve months. The causes of death were worm-complaint and other common ailments, which unfortunately could not have been coped with so successfully as in former years. Statement B. shows the quantity of milk supplied during the year. I have included this statement in order to show that the demand for milk varies within comparatively wide limits from month to month. It will be seen that the demand rose continuously towards the latter part of the year.

These circumstances, and the difficulty experienced in procuring additional stock when required, made it necessary for the Manager to supplement the output of milk at the dairy with milk purchased from outside. But the impossibility of obtaining pure milk in any quantity from external sources naturally gave rise to some unpleasantness with the Medical Department, which it is to be hoped will be avoided in the future.

I would urge upon those who rely upon the lactometer as a test for the purity and quality of milk to see that their instruments are correct by trying them with pure water reduced by ice to a temperature of 60° F., and if found correct to add 4 to the reading of the lactometer at 85° F. and 5 to the reading at 90° F. The temperature of milk should always be taken in Ceylon before using the instrument. Believers in the lactometer would do well to bear in mind (1) that milk can be made to show a high specific gravity by adding foreign matter,

or (what is simpler) by *abstracting* some of the cream by a few turns of the cream separator; and (2) that milk abnormally rich in cream has a specific gravity *below* the normal. In the face of these paradoxical results it will be admitted that the lactometer may often lead its owner astray. My opinion of the instrument is founded on my own experience of its use and on numerous careful tests that I have carried out; but if any one desires to have the views of an acknowledged authority on the subject, I would refer him to Dr. Wauklyn, who, in his work on "Milk Analysis," speaks in this wise:—"From a careful consideration of the whole subject I am convinced that one of the most necessary steps to be taken in milk analysis is to abandon the use of the lactometer."

Statement C. shows the work of the Dairy during the year and needs no explanation.

During 1896, 18 cows were purchased at a cost of R2,510, while 22 cows and 25 calves (9 with their mothers) were sold, the sum realized after paying all the incidental expenses of the sale being R1,257 06.

D. is a financial statement for the Dairy Farm (including Government Dairy, Dairy grass lands, and Model Farm) for the year 1896.

Statement E. shows the financial position of the Dairy Farm in its relation to Government.

F. is a statement of the assets and liabilities of the Dairy Farm. In this last statement no credit is taken for a sum of R4,400 which was paid out of Dairy Funds as compensation to the late lessee of the Model Farm, though the amount is recoverable as value of the "good will" from any future lessees.

GRASS LANDS ATTACHED TO THE DAIRY.

These lands, cultivated with Mauritius grass, constitute the chief source of the Dairy's grass supply. The area under regular cultivation covers an extent of 20 acres. The net income for the year was R776, but this amount should be greatly enhanced as the result of new arrangements for working the lands next year.

THE MODEL FARM.

In the management of the Model Farm (about 220 acres in extent) I have had valuable assistance from Mr. Samaranayaka, an Assistant Master in the School of Agriculture. The total receipts of the Farm in 1894 were R2,506 90; in 1895, R3,001 36; while in 1896 they amounted to R4,269 72.

The expenditure incurred solely on Farm account was R403 89, but an additional sum of R849 77 had to be expended on account of the dry cattle sent there from time to time from the Dairy, so that the total expenditure amounted to R1,253 66, leaving a credit balance of R3,016 06. Deducting from this a sum of R1,350 payable annually as rent to Government, the net income from the Farm stands at R1,666 06.

The pasture land at the Model Farm is not of the best character, being considered by the Veterinary Surgeon too low-lying and wet for the cattle. With the leasing of the Havelock Race-course by the Dairy there will be less occasion for using the Model Farm for pasturing purposes.

The greater part of the high lands of the Farm were during the year laid out as golf links, and named after His Excellency the Governor "The Ridgeway Links."

THE HAVELOCK RACECOURSE.

This was taken on lease by the Dairy from October. It covers an area of over 80 acres, and affords good pasturing for the stock, thus enabling the Manager of the Dairy to make a reduction in his expenditure on grass for "soiling." The proximity of the racecourse to the Dairy is its chief merit, making it possible for it to be used as an exercising ground for the milking cows as well as the rest of the stock. In this way it becomes of special value to the Dairy, which has no suitable land for exercising cattle on the premises. A rental of R60 per mensem is paid to the Ceylon Turf Club for the monopoly of the grazing.

C. DRIEBERG, B.A., F.H.A.S.,

Superintendent.

REPORT by the Superintendent of the School of Agriculture, Colombo, submitting suggestions for the re-organizing and better equipping of the School, and for carrying on the work of the Agricultural Branch of the Educational Department on more practical lines.

Introductory.—Since the School of Agriculture was established in 1884, the departmental policy, which has been pursued in the attempt to bring the native cultivators of the Island under the influence of modern agricultural teaching, as well as to further their interests by adopting such measures as would tend to facilitate their work and improve their condition, has virtually been left to the agricultural instructors to work out. It must needs be inferred, however, from the action of Government in discontinuing the instructors, that the plan hitherto followed, whether owing to the nature of the policy pursued or the manner in which it was sought to carry it into effect, has been found wanting. Under the circumstances I deem it my duty to submit an alternative scheme, drawn up on more practical lines, and, as I consider, better calculated to benefit cultivators in Ceylon. The failure of a first attempt to reach the native agriculturist, so far from deterring the Department from persevering in its efforts, and warranting the desertion of the cause of native agriculture, would, on the other hand, seem rather to call for a fresh attempt on new lines, which later experience may suggest. For this reason I would urge that the vote for agricultural instructors be not allowed to lapse nor be appropriated for other purposes, but utilized for the re-organizing and better equipping of the School of Agriculture, and for carrying on the work of the Agricultural Branch of the Educational Department with better effect.

Site—The availability of the old Normal School buildings no doubt suggested the idea of locating the School of Agriculture where it now stands, but the site, as far as its suitability for agricultural experiments is considered, has proved an unfortunate selection. The extremely poor character of the soil and the difficulties that stand in the way of draining the land have been serious obstacles to the success of the practical part of the work of the school.

Staff of Coolies and upkeep of Grounds.—At present the staff of servants is composed of a messenger or peon, a room boy and indoor cooly, and two outdoor coolies. It will thus be seen that there are only two hands available for the upkeep

of the grounds. I have often had to meet the reproach that the premises are not maintained in an efficient state; but how could this be expected with only two garden coolies at my disposal? I see no reason why the premises should be behind the Victoria Park or Museum grounds in efficiency, both of which institutions are allowed the necessary votes for upkeep.

Originally the school had an isolated situation with a good deal of waste land lying about it; now it is the centre of a much-frequented public resort, and it is a pity that under the circumstances it should wear a neglected appearance. Apart from this consideration, it is important that the surroundings of the students should present lessons in neatness and method; and the garden offers possibilities of being well laid out. I would suggest that a staff of six (*i.e.*, an additional four) outdoor coolies—two good gardeners and four ordinary coolies—be attached to the school. The services of these men would be also available for helping in such cultivation as the students may be engaged in, as it is a difficult matter to carry on systematic work of any extent with the limited amount of labour derivable from the students.

Improvement of Native Implements.—In the early days of the school, and before it came into my charge, a large number of English ploughs were purchased both for the school and for the use of the agricultural instructors, but these implements were eventually found to be unsuitable for the purposes of native cultivation. The purchasing of these ploughs, before at least carrying out preliminary trials with specimen implements, was a mistake. Subsequently a specially-designed plough—called the "Gingalee plough"—was constructed, which, it was thought, would meet the requirements of paddy cultivators, but even this implement did not find favour with them, as it was considered too heavy. Since then no ploughs have been purchased in connection with the work of the school. In spite, however, of past failures, I think that there is still an opportunity of doing good work in the way of facilitating and improving the quality of the work of the native cultivator in the preparation of his land, by further attention to the question of implements. The great point to be attained in the matter of ploughs is to persuade the cultivator to adopt an implement that turns over the soil, which the so-called plough commonly in use does not do, since it has no mould-board—an essential element in every plough. Another mistake that was made in the endeavour to supersede the native implement was to force a novelty in the shape of a foreign plough on the cultivator. The better way of going to work would have been to improve upon the defective implement, and, though earlier alterations may not have been sufficiently effective, to gradually evolve the most approved plough for local requirements, so that the operation of ploughing might be more thoroughly and quickly done than it is now: the modern English plough has been the outcome of such gradual evolution. Another matter which policy would have suggested in dealing with notoriously conservative class is, that the improved implement should have been locally manufactured. I believe that a plough which will meet the requirements of the native cultivator can be made locally. I have had ploughs weighing

only 24 or 25 lb. constructed by native blacksmiths, and these have worked and worn well. I would suggest that the opportunity be afforded to the school for making another attempt, on the lines I have indicated, towards the improvement of the native implements now in use, as well as the introduction, if possible, of other implements and machines—simple forms of sowing and drilling machines such as are now in use in India, for instance—which are calculated to improve the condition of native agriculture. For a beginning, specimens of these latter might be secured for the school for trial and report, and if found suitable one or two of each might be kept at convenient centres, such as Kachcheries, and on application being made to the officers connected therewith the use of the implements or machines allowed and, if necessary, a small fee charged. Again, by exhibiting select implements and machines, and demonstrating their uses and advantages at agricultural shows or special gatherings convened at suitable centres, much can be done to bring them to the notice of cultivators.

New and improved varieties of Seeds and Plants.—Another important matter about which the School of Agriculture should concern itself is the distribution of seeds and plants. It is of great importance that paddy cultivators should be given facilities for exchange of seed and for the purchase of fresh seed from other districts than their own, as well as for procuring new varieties of seed which might with advantage be introduced into the Island from abroad. There are varieties of paddy not to be obtained in Ceylon which, owing to their possessing special characters suited to the special conditions which obtain in particular districts, can be introduced into the Island to the benefit of cultivators. In introducing such new varieties it might be arranged that before distributing the seed (which as imported would be a comparatively small quantity) among growers, a crop should be raised under the auspices of the Government Agents. Indeed, any measure directed towards the improvement of native agriculture must largely depend for its success upon the help and co-operation of the Revenue Officers. Seeds of other desirable grain or food crops and seeds and plants of fruit trees suitable for cultivation here should be procured and kept at the school, and offered for sale at reasonable rates, so that the country may be benefited by the growth of a larger variety, and of improved and new kinds, of food crops and fruit trees. There is much that we can do in this way in improving native agriculture and in encouraging fruit culture in the Island, by giving facilities to would-be growers for procuring seeds and plants which at present they do not know how or where to get. In certain remote parts of the Island such well-known food-supplying trees as the jak and breadfruit are unknown, while arrowroot is unknown in other parts. It will thus be seen that there is a good deal to be done even in helping to spread the cultivation of indigenous and naturalized trees with immense benefit to the poorer classes in remote districts of the Island.

Publications: Advantages of circulating Leaflets.—I would also suggest that pamphlets, bulletins, and leaflets containing information of value to the agriculturist, with reference to methods of cul-

ture, manures, crops, stock, &c., should be published in English, Tamil, and Sinhalese (if possible with illustrations), and circulated free among the agricultural classes with the help of the Revenue Officers. This is a convenient and recognized means of reaching the people which is adopted by Agricultural Departments in India and elsewhere, and from my own experience in the publication of the "Agricultural Magazine" and in the issue of leaflets in the vernacular (now unfortunately abandoned for want of funds) I can state that the means have proved effectual in evoking an intelligent interest in much that should concern the cultivator of the soil.

Students to be taken on Tour.—In order to make the course of training at the school as thorough as possible, I would recommend that the students be taken on tour during one month of the year, so that they may gain practical acquaintance with the cultivation of Ceylon products as carried on a commercial scale. The necessity for supplementing what is at the best a limited knowledge of practical—but more or less experimental—agriculture gained at a college, by the wider and useful experience that would be afforded by such tours, is recognized by the promoters of agricultural education in England and India; and it is a pity that any element should be wanting in the course of training provided at the school which would tend to make that course as complete as it might be, and go to disprove the charge that the students are lacking in practical experience.

The Superintendent of the School to itinerate.—It is very necessary that provision should also be made to enable the Superintendent to itinerate through the Provinces in order to study native agriculture in all its phases, and acquaint himself with the special features which characterize the various forms of cultivation in the Island: to find out the needs of the people, to confer with village authorities, and, where opportunity offers, to advise and instruct with reference to agricultural practice. As the result of these tours the Superintendent should furnish reports to Government. I think it would be an encouragement to the native cultivators to have some one taking an active interest in their work and welfare. I do not mean to insinuate that no such interest is evinced by the Government Agents and Assistant Government Agents. They are no doubt doing all they can in the cause of native agriculture, but the duties of the Superintendent in this connection will be of a special nature. During such tours much can be done in the way of distributing seeds, leaflets, &c. There are whole Provinces—and many districts—that I have not yet had an opportunity of visiting. A practical acquaintance with the methods and forms of culture adopted in different Provinces and districts should place me at a great advantage whenever I am called upon to report and advise in my official capacity (or when privately consulted) on agricultural matters. Some of these tours of inspection might be undertaken during school vacations.

A Clerk to be attached to the School Staff.—I would urge that a clerk, on a salary of say R25 per mensem, be attached to the school, to undertake the comparatively large amount of clerical work and book-keeping which has to be attended to in connection with the School and Dairy Farm, the greater part of which at present falls to the lot

of the Superintendent. The appointment of a clerk should relieve me considerably, and by confining me less to my office leave me free to do more work of an important practical nature. I may mention that a properly furnished office room, to which the many business callers at the school could be shown, is a great want.

Expenditure on the School.—There is a general impression abroad that the expenditure on the School of Agriculture is excessive; and in considering the cost of the institution to Government the fact that there is a considerable revenue from the school and the establishment appertaining to it is seldom recognized. The work of an agricultural school or college, if it is to be at all effective, must be based on a comprehensive and complete scheme, and the necessary funds should be available for carrying out the details of such a scheme.

Savings and Estimates.—The following statement shows how Government will practically save a sum of nearly R9,000 from January, 1897:—

By the abolition of agricultural instructorships, 6 at R528 per annum and 6 at R396 per annum	5,544
By raising of the fee for agricultural students from R5 to R10 per mensem (a measure which came into force in January, 1896) the vote for dieting students will be practically saved	3,000
By lapse of vote for travelling by Superintendent to inspect the agricultural instructors	200
Total	8,744

I beg to recommend that part of this saving be utilized for better equipping the school and in giving a more useful and practical turn to the work connected with the agricultural branch of the Department of Public Instruction. The following is an approximate estimate of the cost of carrying out the recommendations made in the above reports:—

Cost of extra hands, 2 at R15 and 2 at R10	600
Cost of laying out and maintaining premises, including cost of implements, manure, fences, cart, bulls, &c.	800
Exchange and purchase of seeds and plants, storing, maintaining nurseries, distributing, &c., together with cost of implements for trials and report	800
Cost of printing and circulating leaflets, &c.	400
Vote for itinerating by Superintendent	600
Cost of taking agricultural students on tour	800
Salary of clerk	300
Miscellaneous	700
Total	5,040

I have endeavoured to make the estimates as low as possible. Considering the cost of a visit to the Eastern or the Northern Province, the vote for itinerating by the Superintendent is by no means high. The miscellaneous vote would provide for the undertaking of special experiments under ex-

ceptional circumstances, and need not be an annual expenditure. The trial in vine-growing at present going on is such an experiment.

Agricultural Shows.—I would urge upon Government the importance of drawing up a scheme for holding agricultural shows at short intervals at different centres. These shows should be of a purely agricultural character, held mainly in the interests of native agriculture. Such shows are frequently held in India, where it is acknowledged that the native cultivators have derived material benefit from them.

Employment of trained Students.—Whenever possible students who have had a training at the School of Agriculture might be appointed to posts that would bring them in contact with the agricultural classes, particularly where such appointments would give them a certain amount of influence over the people. Of this nature would be the appointments of native writers and other posts in the Revenue Department carrying salaries of less than R600 per annum, as well as of minor forest and irrigation officers and officers appointed for special agricultural and veterinary work.

Further development of the School.—I have thought that with the help and through the influence of the Revenue Officers it would be possible to arrange for a curriculum for vernacular students (to be nominated by the Revenue Officers) drawn from the classes to which the rural native officials belong, with a view to giving an agricultural training, lasting for one or two years, to those who would be eventually employed as police

officers, peace officers, vel-vidanas, fiscals' arachchies, division officers, constable arachchies, &c.

Special provision might also be made at the school for the sons of wealthier landowners who may desire to avail themselves of a course of agricultural training. For such somewhat better arrangements as regards accommodation and diet might be provided on their paying a higher rate of boarding fee. It would be an advantage if surveying could be added to the subjects in the agricultural course, by arrangement with the teacher of surveying in the Forestry School.

I would again emphasize the importance of providing for a practical veterinary training for the students.

In case the recommendations referring to changes in the school are approved of, I shall be prepared to revise the present printed syllabus and bring it up to date for re-publication.

In conclusion, I may state that some of the suggestions embodied in this report have been put forward by me from time to time in my annual reports, in reports read at public prize givings, and in my official correspondence. A want of funds and other causes would seem to have stood in the way of any such suggestions being adopted. I would earnestly press upon Government (1) the necessity for adopting some definite scheme for agricultural work in connection with the Educational Department; and (2) of providing the funds necessary for satisfactorily carrying out all the details involved in such a scheme. With these provided, there will be an opportunity of doing really useful work.

A.—RETURN OF GOVERNMENT DAIRY STOCK FOR THE YEAR 1896.

Cattle.	Balance on hand on December 31, 1895.	Purchased during the Year.	Born during the Year.	Total.	Died during the Year.	Sold during the Year.	No. to be struck off the List.	Balance on hand on December 31, 1896.
Cows	74	18	—	92	5	22	27	65
Calves	65	—	52	117	34	25	59	58
Stud bulls	2	—	—	2	—	—	—	2
Draught bulls	2	—	—	2	—	—	—	2

B.—STATEMENT SHOWING SUPPLY OF MILK DURING 1896.

Month.	Supply. Bottles.	Month.	Supply. Bottles.
January	8,779½	September	8,855½
February	7,819	October	8,875
March	7,552	November	9,041½
April	7,495	December	9,273½
May	8,116		
June	7,713¾		
July	8,187¾		
August	8,762½		
		Total	100,491

Of these 100,491 bottles, 25,692½ bottles had to be purchased from outside sources. Total output of milk at the dairy = 74,798½ bottles of 26 oz., or nearly 12,500 gallons.

C.—FINANCIAL STATEMENT OF THE GOVERNMENT DAIRY FOR THE YEAR 1896.

<i>Receipts.</i>		<i>Amount.</i>		<i>Expenditure.</i>		<i>Amount.</i>	
		<i>Rs.</i>	<i>c.</i>			<i>Rs.</i>	<i>c.</i>
January ...	Realized by sale of milk, manure, &c. ...	1,626	29	Paid to the Maanger as salary during the year	465	00

WILLIAM MARTIN LEAKE.

* The TROPICAL AGRICULTURIST *

◇ MONTHLY. ◇

Vol. XVII.]

COLOMBO, OCTOBER 1ST, 1897.

[No. 4.

“PIONEERS OF THE PLANTING ENTERPRISE IN CEYLON.”

(Second Series.)

MR. W. MARTIN LEAKE,

ENGINEER, PLANTER AND MERCHANT:—1859—1873.

It is much more difficult to deal with the careers of “pioneers” and “public men” who are still in the land of the living, than with those who have already passed that “bourne whence no traveller returns.” And

this is especially true when the subject of our notice is a personal friend, and an ex-Colonist so very generally liked and esteemed as is Mr. William Martin Leake, the well-known Secretary of the Ceylon Association in London. But apart from the fact that Mr. Martin Leake’s career has been nearly all contemporary with our own—and open before us as that of a public man, almost from first to last—we have had the great advantage of securing “notes” of that portion of his life of which we could know nothing, written, though reluctantly, at our earnest request.

We trust the use made of this information in the story of the varied career of a Ceylon Colonist of a past generation will tend to the benefit of his successors in the present day. It is something to bring before young Colonists of the present day the career of a man of culture and high professional training, who, nevertheless, entered on the ordinary and sometimes rough work of the pioneer—at least as Engineer—with the utmost zeal and pluck, and whose further experience as a Merchant, Planter and Public Man in Ceylon was uniformly marked by transparent

honesty, straightforward devotion to duty and no small degree of self-denying interest in the welfare of subordinates and young employes. Mr. Martin Leake’s work as Secretary to the Planters’ Association (and for a term as Chairman and M.L.C.) alone entitled him to the gratitude of his brother Colonists, a gratitude which is still further enhanced by the continued good work for the Colony he is discharging as the Secretary of the Ceylon Association in London. But we must not plunge into the middle of our subject. We cannot better begin than by giving the following concise “chronology” for ready reference in regard to the, happily, still unfinished career of Mr. Leake:—

1831.—Born in Montagu Street, Bryanstone Square, on 23rd April, St. George’s Day. [Birthday of one W. Shakespeare.]

1836.—Went to a Boarding School in Bayswater Village, kept by a lady.

1837-40.—At school at a day school in Upper Baker Street.

1840-45.—At the New Proprietary School, Blackheath.

1845-50.—At Rugby.

1850-54.—At St. John’s College, Cambridge.

1855.—Travelling in Italy, Sicily, Austria, Germany and France.

1856-58.—Apprenticed to J. M. Rendel, C.E., President of the Inst. C. E. On his death at end of 1856, served out time with his executors—his sons Messrs. M. & G. Rendel, (former of whom is now Sir A. M. Rendel, K.C.I.E.) and Mr. W. G. Armstrong of Elswick (now Lord Armstrong). These years were divided between official work in Great George Street, Portland Breakwater (the late Sir J. Coope was in charge there), Shadwell Basin, London Docks, and the Elswick Works.

1858-59.—Assistant Engineer at the new Dock, Leith, under G. Robertson, F.R.S.E., who afterwards reported to the Harbours of India, visiting Ceylon in 1872.

Oct. 1859.—Sailed for Ceylon to join G. D. B. Harrison, then carrying out Irrigation works in Southern Province.

1860-61.—In Ceylon in Southern Province—Kirime, Tissamaharama, and Paddegama.

Oct. 1861 to June 1862.—At home. Married 6th Nov., 1862, at Galle, Louisa, youngest daughter of Sir James Tennent, K.C.B.*

1862-1873.—Partner in Keir, Dundas & Co.—1869 and 1870 were spent in England—in 1870 made a tour in Russia, St. Petersburg, Moscow, Nijni Novgorod, and Odessa, to promote direct coffee trade through Suez Canal then just open.

1873.—Left Ceylon.

1874-1896.—Started Tunnel Portland Cement Works Co. and is still managing it.

In the case of Mr. Martin Leake we are able to begin at the beginning with an explanation as to the origin of the

FAMILY NAME.

This double name, we find, dates from the beginning of 18th century. In the time of William and Mary and Queen Anne there were in the Royal Navy two officers of distinction, Admiral Sir John Leake and Capt. Stephen Martin, who married two sisters named Hill. On the death of the former in 1719, without living issue, he left to his old shipmate all his lands and money, value some £30,000, on condition that the latter assumed the name of Leake. By letters-patent of George I., dated December, 1721, Capt. Stephen Martin accordingly became Capt. Stephen Martin Leake. These two old naval worthies have not, like the many brave men before Agamemnon, perished unknown. The "vates sacer" has been found in Stephen Martin Leake, Garter King-at-Arms, son of Capt. Stephen Martin, who compiled from original documents a full and detailed Memoir both of his father and also of Admiral Sir John Leake. The latter he published himself in 1750, and the book though scarce is still obtainable. The Memoir of Capt. Stephen Martin was published so lately as 1895 by the Navy Records Society, Sir Clements Markham being the editor. The grandson of the Garter King-at-Arms referred to above was Stephen Ralph Martin Leake of the Treasury—who, in 1831, when his youngest son William was born, was official Private Secretary to Lord Grey, then Prime Minister.

The

SCHOOL-DAYS

of young William Martin Leake began early, owing to a prolonged absence in Ireland, on Government business, of his parents. His first school was in the then little country village of Bayswater. From his house in Nottingham Place, Regent's Park, William Leake can remember walking across fields where now are Westbourne Terrace, Lancaster Gate, &c., to the school situated in the present Queen's Road. The Great Western Station at Paddington was then in course of construction, and Master Leake was next removed to Blackheath to a Naval Proprietary School which was started sometime in the "thirties" in opposition to an existing old Proprietary School which is to this day a flourishing institution. One of its chief promoters was Mr. Meadows White, Solicitor, grandfather of the gentleman now or lately Private Secretary to the Chief Justice of Ceylon. For the better

edification of the pupil mind, a concrete structure after the model of the Parthenon was erected and divided into class-rooms. The school flourished for a few years, but soon languished. It must have been closed and the Greek temple pulled down some 40 years ago. But recollections of it have been lately stimulated by Sir Stuart Knill, who, during his recent mayoralty, gave a dinner to all such of his schoolfellows there as he could find. Forty-two old boys met that evening at the Mansion House, all probably over 60 years of age, most meeting after a separation of about half-a-century, a unique gathering. Three Messrs. White, sons of the Mr. Meadows White above-mentioned, were present.

Next we have young Mr. Martin Leake at RUGBY.

In 1845 Dr. Tait, after an exciting contest with Dr. Wordsworth, had comparatively recently succeeded to the headmastership on the death of Dr. Arnold. Arthur Stanley's life of Arnold had just been published, and Rugby was steeped in Arnoldism. Mr. Leake went to the house of Mr. Bonamy Price, afterwards Professor of Political Economy at Oxford. To the same house at the same date, from the old Proprietary School, Blackheath, came G. S. Goschen, now First Lord of the Admiralty, also (though not from Blackheath) William Palliser, brother (it is believed) of the Pallisers of Radella, famous afterwards for chilled shot and big guns. Even in his schooldays young Palliser used to have an illicit gun.

In 1849-50 Mr. Goschen became head of the school. In the upper forms all lessons were learned out of school in the home studies, generally two or three preparing the work together.* For the last two to three years, in the Sixth Form, Mr. Martin Leake was thus associated in daily intercourse with the future Cabinet Minister. Another Rugby contemporary, afterwards well-known as a Ceylon planter, was the late Mr. William Greenwood of Gona Adika and Wattekelle.

Now we come to Mr. Martin Leake's

UNIVERSITY DAYS.

Among contemporaries at St. John's, Cambridge, were Mr. Leonard Courtney and Sir John Gorst. Mr. R. (afterwards Sir R.) Cayley came up in 1851, and in the Lent Term Races of 1852 steered the "Lady Margaret" second boat, in which Mr. Martin Leake was rowing. The boat was fifth on the river, and in the vain hope of maintaining that high place—vain because the boat lost one or two places—the crew was kept in pretty strict training. The constant association during these weeks of training was the beginning of the life-long friendship between the then coxswain and oarsman "Dick" Cayley, always so called to distinguish him from his elder brother Edward who was in the year above, and afterwards steered the "Lady Margaret" first boat, as head of the river in 1854 and had a great reputation as a judge of good rowing. In October, 1850, when Mr. Martin Leake went up, Mr. Arthur Gordon (now Lord Stanmore) was still an active member of the Union. Other leading speakers were William Vernon Harcourt and James Fitzjames Stephen. Later, Leslie Stephen, James Payn, and H. Montagu Butler come to the mind as leading lights. Mr. W. Martin Leake was a scholar of St. John's, and in 1854

* Sir James Tennent of the Bengal Artillery, made K.C.B. for distinguished services in the Sikh Wars. W. M. L. has nine surviving children.

* See life of Bishop T. V. French of Lahore, Vol. 1, pp. 5 to 7.

was 29th Wrangler and in the second class in the Classical Tripos.*

CRICKET,

both at school and in college, received from Mr. Martin Leake, much time and attention. Blackheath in the "forties" was a very nursery of cricket. Kent with Fuller Pilch, N. Felix, the brothers Myynn, Wenman, &c., as its champions, had

* Mr. Leake has favoured us with the following notice of "Rugby" and "Cambridge" in his day, which is well worth reproducing:—

Rugby 50 years ago was thoroughly penetrated with the spirit of Arnold. Though the great headmaster had in 1845, when W. M. Leake went there, been for three years dead, and his mantle had thereon fallen on Dr. Tait, the future Archbishop; the staff of masters were nearly all Arnold's men who had been appointed by and worked with him during the stirring years of his headmastership. Further, the recent publication of his life and correspondence by Arthur Stanley had made more widely known than was possible during his life-time the nature of his work at the great midland Public School. Dean Bradley (Westminster), Prof. J. C. Shairp (St. Andrews), Prof. T. S. Evans (Durham), Canon C. Evans were also masters of Rugby between 1845-50.

Chief among the assistant masters at that date were Bonamy Price, afterwards Professor of Political Economy at Oxford, and George Edward Lynch Cotton, afterwards headmaster of Marlborough and Bishop of Calcutta, the "young master" of Tom Brown's school days. These two taught respectively "The Twenty" and "The Fifth," the two forms next below the Sixth. Never probably have boys had a more lively teacher than Bonamy Price, "an alert and stimulating man" as the writer of an obituary notice styled him. "In the Twenty," Price put on the spur and kept us up to our best. He was an excellent master whom we all thoroughly liked and appreciated, all the more perhaps on account of his "lively eccentricities," so writes the Very Rev. G. P. Pownall in his contribution to the Memoir of Bishop French of Lahore. Cotton, though quieter and colder in manner, was also a very efficient teacher. The two had this in common, that they were at their very best in lecturing on the New Testament, in *Exegesis* as Price loved to call it.

Another notable master, who had a lower Form, was Richard Congreve, the disciple of Comte, who afterwards was, at it were, the High Priest of Positivism in England. He it was who in 1848, when the thrones of Europe were reeling under the strokes of the all-pervading Revolution, stirred the fags of the school to rise and throw off the thralldom of the Prepositors of the Sixth Form. Excited meetings were held in the Quad at which fiery harangues were delivered, but all in vain. The Sixth proved themselves too strong for their more numerous foes, backed though they were by a Radical master.

It was to Bonamy Price's house that W. M. Leake went in the summer of 1845. He had the fortune at once to be chosen as a fag by George Lawrence, then head of the House, afterwards well known as the author of "Guy Livingstone," "Sword and Gown," and other novels. Strange as it may seem to those who know him only by his books, there can be little doubt that Lawrence was himself the original of his own heroes. Life in his eyes was not worth living unless as a series of thrilling incidents; he had no wish to live beyond the age of thirty, he would say, and meanwhile he would thoroughly run through every excitement that life can offer. He has now long been dead, though he lived for several years beyond the limit of his own naming.

Among those who came to Price's house in that same summer were George Joachim Goschen, now First Lord of the Admiralty (like W. M. Leake he came from Blackheath, but from the rival Old Proprietary School) and William Palliser, brother of the Pallisers of Radella, afterwards knighted for his inventions in connection with Big Guns and Chilled Shot. Even in his school-days Palliser shewed his leaning for firearms, for he managed to secrete an old shot-gun in his study, which had the reputation of shooting

played the rest of England on equal terms year after year at Lords and Canterbury; and Blackheath and its schoolboys—especially those who were at the school kept by Mr. Wanostrocht (that was the true name of the great Felix)—felt as if they shared in the glory of the country. Enthusiasm thus engendered at school was for Mr. Martin Leake further stirred by the proximity of his home to "Lords," where at a very early age he used to see and criticize all the leading players of the

round the corner, but none the less on occasion it would provide its owner with a stray pheasant, partridge, hare or rabbit, a savoury addition to the somewhat meagre school-fare of those days.

W. M. Leake did not remain long a fag, was moved quickly up through the various Forms, arriving safely in the desired haven of the Sixth Form in January 1848. In the upper Forms all lessons were prepared out of school, in the house studies, two or three preparing the work together. Mention is made of this custom in the sketch of Rugby in the Memoir of Bishop French already referred to. In that case Pownall, the writer of the sketch, was associated in this way with French, the future Bishop, and Cross, now Lord Cross. The companions of W. M. Leake, in lesson-learning during the years 1848-50 were G. J. Goschen and J. P. Beck, the latter, the eldest son of the late Mr. S. A. Beck, Chairman of the Gaslight & Coke Co. from whom that hive of industry, the Beckton Gasworks, takes its name. This system, giving life as it does to what is apt to be, when done alone, a work of deadly darkness, is an admirable one. Learning lessons under it became one of the most lively and sociable parts of the day.

In 1849-50 Goschen became Head of the School; and the year of his Headship is marked in the annals of Rugby by the departure of Dr. Tait, whose health had for some time been very indifferent, on his appointment to the less onerous post of Dean of Carlisle. This was probably the first occasion on which the future Cabinet Minister had a genuine opportunity for showing his powers of speech. Few masters can have had a more touching leave-taking than Dr. Tait on this occasion. The boys dragged him down to the Railway Station in his carriage, and the last scene in the stationyard dwells to this day in the memory of the survivors of those present. For the last few months of the school career of those who were leaving in 1850, the school was presided over by that excellent man Dr. Goulburn, but good as he was he was never meant by nature for a schoolmaster.

On looking back to the Rugby of those days, one of the most striking features is the number of distinguished schoolmasters sent out by the old school to propagate the Arnold tradition through the length and breadth of the land. Already in 1845 Dr. Vaughan, one of Arnold's pupils, was presiding over Harrow. Dr. Bradley, now Dean of Westminster, also a pupil of Arnold's and a master at Rugby in W. M. Leake's time, succeeded Dr. Cotton as headmaster of Marlborough on the appointment of the latter as Bishop of Calcutta. Mr. A. G. Butler and Dr. T. W. Jex Blake, both contemporaries and friends of W. M. Leake, became headmasters respectively of Haileybury and Cheltenham, the former being succeeded in his post by Dr. E. H. Bradley, head boy at Rugby in 1845, the latter succeeding in his Mr. H. Highton who had been both pupil and master at Rugby in Arnold's time. Dr. Jex Blake, alone among the Headmasters of Rugby of the last 70 years, was himself a Rugby boy. Further, Mr. Charles Evans (now Canon Evans) and Dr. Percival (now Bishop of Hereford) and the late Dr. Benson (Archbishop of Canterbury) all Rugby masters in the early "fifties" presided over Birmingham, Clifton, and Wellington respectively. To these who all became headmasters might be added the names of efficient assistant masters too numerous to mention. In the case of Arnold it cannot be said that the good he did was "interred with his bones."

(Continued next page.)

7. Going to Rugby, Mr. Marlin Leake had the advantage in his later years there of the instruction of old William Lillywhite and his son Jack. "Old Lilly," as he was called, was the inventor of round-arm bowling, all bowlers before his time having delivered the ball underhand; and for a time so destructive was the new style of bowling, that a rule was made that in delivering the ball the hand must not be raised above the shoulder. Bowling under this limitation "Old Lilly" succeeded by close and prolonged practice in acquiring an accuracy of pitch

(Continued.)

In October, 1850, W. M. Leake went up to St. John's College, Cambridge, while his friends, Messrs. Beck and Goschen, at the same date betook themselves to Oriel College, Oxford, where they both carried off high honours, their names appearing in 1854 in the First Class in *Literis Humanioribus* in the same list. Oriel men had not for some years previously shone in the schools, and so delighted was the Collee at this unwonted double success, that a great feast was made to celebrate the event, whereat a silver punch-bowl that graced the board was presented to the two brilliant students. Both could not hold this memento of their College days, so by the toss of a coin it was decided that it should become the property of Mr. Beck. On his death, however, it was transferred to the hands of Mr. Goschen, to be handed down doubtless as a treasured heirloom to his successors.

The changes effected in Cambridge in the past half century, though very striking both to the outward eye and also in the inner life, are probably hardly so great as those in the great Public Schools. In 1850 the studies of the University were almost confined to Mathematics and Classics, Mathematics still taking the precedence, as, for hours a certain modicum thereof was still indispensable. Cases still occurred of brilliant scholars being debarred, as was Lord Macaulay, from their due place in the Classical list owing to their failure in Mathematics. As with the studies, so with the athletics. These were confined to Cricket and Rowing. There was, it is true, one Tennis Court and one open Racket Court, but the players at these games were perforce very few. Football, Lawn Tennis, the Rifle Corps, the Athletic Sports, all now so popular, were things as yet unknown. The majority of reading men had to satisfy themselves with a constitutional of a couple of hours along the Trumpington road or elsewhere.

In the interval there have sprung up on the one hand well-equipped Laboratories, Technical Schools and Workshops; on the other Football Grounds, Tennis and Racquet Courts, Running Tracks, &c., Rifle Ranges. Another case in point is the Union: in 1850 the whole establishment was contained in one small room in Green Street, formerly a chapel, with a gallery round, lined with shelves whereon the books were kept; "a very one-horse affair" so said James Payn recently when writing on the subject in "Our Note Book" in the *Illustrated News*. Now how changed is all this! The present noble range of buildings with its spacious hall for debate, its library, reading room, writing room, smoking room, &c., affords to the members all the conveniences of a West End Club.

Another change noticeable by the undergraduate of the mid-century revisiting today his old University is in the style of dress. Top hats and black coats, which, in 1850, were the everyday non-academical costume, are now not to be seen. Light-coloured coats, straw hats, and caps are worn by all; no kind of free and easy garment is considered *infra dig*. To note the difference let any one, after a stay in the Cambridge of today, glance at Cuthbert Bede's pictures in "The Adventures of Mr. Verdant Green,"—book first published about 1850. Even Mr. Charles Larkyns and little Mr. Bouncer, the lively young gentlemen who took in hand Mr. Green on his arrival in Oxford as a Freshman, are depicted as riding and driving arrayed in tall hats, while Verdant himself is to be seen sculling on the river in the same headgear,

that probably has never been excelled: not bowling very fast, but keeping always on the wicket and varying the pitch at will he was an ideal practice bowler, while his son Jack, also a fair bowler, was besides a dashing batsman who could teach the young player by example no less than by precept. For three years Mr. W. Martin Leake played in the Rugby School Eleven, and on going up to Cambridge at once found a place in the University team. For the four years (1851 to 1854) he played in every match in which the University was engaged. In each of these years he played against Oxford at Lords. In the first year, 1851, when Cambridge won in one innings he had the fortune to make 66, the biggest score made in the match by any Cantab up to that date. In 1857, the first match of the series, an Oxonian made 71, but up to 1851 there was no other instance of a score over 60. Things are different in these days of centuries. The reasons are, no doubt:—(1) The better condition of the grounds. The wickets at Lords in the early "fifties" would not be tolerated today by any fairly good country club. Playing against fast bowling, even at Lords, was then a service of real danger. The improvement in the grounds it was that later brought about the abolition of the rule forbidding the raising of the hand in bowling. (2) The system of boundaries which saves the breath of the batsman. In 1851 Mr. W. Martin Leake had to run out every hit, and in the innings mentioned at Lords was run out trying a fifth run. Boundaries, now rendered necessary by the attending crowds of spectators, had no place at a time when, even at the most important matches, a single row of movable benches gave full accommodation to all-comers. The thin line of spectators jumped from their seats to let the ball and fielder pass and repass. During the present season it has often been remarked, when Mr. Jessop has been driving ball after ball at almost lightning pace to the boundary, how inadequate is an allowance of 4 runs for such mighty strokes. The comment is just only on the surface. Had Mr. Jessop been obliged to run out each hit, as of old, he might indeed have converted many of his fours into fives, sixes, or even sevens. But how about the next stroke? Under the present system he has been able to score a second and may be a third four without running a foot in a shorter time than would have been needed for running out the first big hit. To score at the rate of two or three runs a minute, as Mr. Jessop has often been doing, and to continue the performance for half an hour and more, would, without boundaries, be a superhuman task.

To return from this digression. When Mr. W. Martin Leake went to live in Kandy in 1862,

CRICKET WAS LITTLE PLAYED UP COUNTRY:

he lost no opportunity of encouraging the game. Organizing an eleven from among the Superintendents in his Firm's employment, he challenged the rest of the planters, and for several years this match was the occasion of a pleasant gathering in Kandy. On the opening of the Railway to Kandy in 1867, Colombo was promptly invited to bring up a team to play Upcountry. This, the first of very many succeeding contests, was a most exciting game, the visitors being defeated only by five or six runs. With Mr. T. E. B. Skinner, then Fiscal for the Central Province, Mr. W. Martin Leake about the same date started the Kandy A.B.C. (Athletics, Beating, Cricket) Club which, with the addition of one

more letter (D), lived for a space of well-nigh thirty years, and came to its end only last year.

After Cambridge, Mr. Martin Leake made
A TOUR ABROAD.

The Crimean winter was spent in Rome. There he met the late Mr. A. H. Baillie who was travelling with his mother and sisters. Early in 1855 Mr. A. H. Baillie returned home to go out to Ceylon, where, subsequently, he and Mr. W. M. Leake were on very friendly terms as Proprietor and Agent. Messrs. Lightfoot and Benson, afterwards Bishop and Archbishop, were there also. Mr. Leake had known them at Cambridge; and with Mr. Benson, as being then a young Rugby master, there was a connecting link. Mr. Martin Leake belonged to the Artists' Club for the winter; there he met Mr. Leighton just about to exhibit at the Royal Academy his first picture, the "Procession in the Streets of Florence," about which all Rome was talking. With three others he walked through the length of the Volscian Hills from Albano on to the rail at Capua, saw no brigands though warned to expect them—people all very kind and civil. From Rome Mr. Leake went to Naples, saw a fine eruption of Vesuvius, to Sicily (ascended Etna), to Leghorn, Florence, Bologna, Padua, Venice, thence to Trieste, Vienna, Salzburg and the Tyrol, Munich, Prague, Dresden, Berlin, Hamburg and home.

Next we come to Mr. Leake's

APPRENTICESHIP AS ENGINEER.

An interesting item, as bearing on present controversies is the expenditure by London Dock Company in 1855-59 on construction of Shadwell Basin. To make this comparatively small area of Dock the Company spent about £1,000,000 sterling, half the sum being expended in buying up and pulling down streets of houses. The Dock Company's shares fell under this expenditure from par to below 6s, and have never risen again. Simultaneously the present Victoria Dock, just below Blackwall, was being made, G. P. Bidder being Engineer, by an independent Company on the Essex marshes where land was still cheap, and the London Dock subsequently bought up this much larger and more convenient Dock in self-defence, adding to it in 1878 and 1879 the Royal Albert Dock, the largest Dock of all. Sir A. M. Rendel is still Engineer to the London Dock Company as his father was 40 years ago. It was at Shadwell, in 1856, that Mr. W. Martin Leake first met his old friend and once partner, Mr. G. D. B. Harrison. Early in 1857 Mr. G. D. B. Harrison went out to Ceylon as one of Capt. Moorson's staff for the Ceylon Railway.

At ELSWICK Mr. W. M. Leake saw the *second* Armstrong Gun made. This gun was taken to Woolwich to practise against the Royal Artillery. Its performance was such as to make absolutely necessary an immediate and complete revolution in big guns. It will be remembered that Mr. Armstrong was put in charge of the Woolwich Arsenal and given a free hand to the great discontent of Whitworth. Such a weapon as the Armstrong gun of that date, the bore with 40 spiral grooves and a shot with lead lining, has long disappeared from the scene.

LEITH.—One of the pleasantest years was spent in Edinburgh in August 1858 to August 1859. Unbounded hospitality awaited the Southron, especially one who was able and willing to play cricket, rackets and to row. The late Lawrence Mereer, once Manager of the Ceylon Co., Ltd., was then Secretary of the St. Andrew's Boat

Club, and there was a lively time generally. G. Robertson, the Resident Engineer of Leith Docks, was eldest son of Lord Benholm, one of the Judges, so the Assistant Engineer did not want for introductions.

In 1859, while at Leith, Mr. W. Martin Leake received an invitation from his old fellow-pupil, Mr. G. D. B. Harrison,

TO JOIN HIM IN CEYLON

where, Sir H. Ward being Governor, money was being freely spent by the Government on Irrigation Works, &c. The offer, seeming to be a promising one as regards prospects, was accepted, and in October of that year Mr. W. Martin Leake sailed from Southampton for Galle. Alas! for the future prospects—by the middle of 1860 Sir H. Ward left Ceylon for Madras, and Sir C. MacCarthy came out with orders to stop all expenditure that could be dispensed with, and then at once set in the period of "parsimony" so ably reduced to practice by that most economising and worthy of public officers, Mr. William Charles Gibson, who had succeeded the new Governor as Colonial Secretary. The young Irrigation Contractors were plainly told that they need look for no more work; and there was nothing for it but to wind up, realize profits, and look elsewhere for occupation. So ended the short-lived firm of Messrs. Harrison and Leake.

One evening in the latter half of 1860 and 1861 Mr. G. D. B. Harrison and Mr. W. M. Leake, dining at the Galie Face Hotel, Colombo, met Mr. John Anderson and family on their way to Galle homeward-bound, Mr. J. Anderson having been ordered home for health's sake with injunctions never to return. This sudden departure had, it seemed, quite upset the plans of his uncle, Mr. John Gavin, whom he was to have joined as partner in the Firm of Keir, Dundas & Co. Mr. Simon Keir had already arranged to retire from that Firm, and Mr. G. H. Dundas, who was at home, was anxious to retire if some one could be found to take his place, so that Mr. Gavin was likely to become the sole survivor of the three old partners. Negotiations were at once opened with Mr. Gavin which resulted in a very few days in Mr. G. D. B. Harrison taking an active share in the work of the Firm, while Mr. W. M. Leake went home for a few months' holiday. The upshot was that on 1st July, 1862, Mr. G. H. Dundas retired from, and Mr. G. D. B. Harrison and Mr. W. M. Leake were admitted as partners into, the Firm of

KEIR, DUNDAS & CO., KANDY.

A few words on the vicissitudes of fortune of the once famous Coffee Firm may be interesting, and perhaps useful as a warning, in the present days of unclouded prosperity in Tea. Probably no Ceylon Firm has ever had a brighter time than Messrs. Keir, Dundas & Co. enjoyed during the ten years, 1854-64. In the former year its dealings were on a humble scale; in the latter all three partners had retired on handsome fortunes leaving to their successors a well-secured and apparently most valuable agency business. In 1864-66 came a time of trouble enough to try to the utmost the strength of the Firm. First, the failure in Colombo of Messrs. Wilson, Ritchie & Co., with whom many joint ventures existed, involved considerable liabilities; then, in quick succession in London of two houses, Charles Joyce & Co. and Kelson, Tritton & Co., to whom sums were due; and lastly, several natives to whom advances had been made, succumbed in the general financial disturbance that accompanied the close of the American Civil War, and culmi-

nated in the Black Monday in May, 1866, when the city of London was a scene of panic such as has not since been witnessed.

Many of the properties on which the Firm had claims were owing to these failures thrown on a market where there were no buyers; and the position involved this dilemma, either serious losses must be faced or money must be found to buy in the properties in question, on which in most cases there were prior charges. The latter alternative was adopted, and before the end of 1866 the Firm, which had hitherto been mainly an Agency business, became sole owners of the Uplands and St. Sebastian Mills in Colombo, as well as the largest Coffee Estate Proprietors in the Island, the properties being necessarily subject to a somewhat heavy, though by no means as far could then be seen, crushing debt. Simultaneously the course of events had thrown into the hands of the Firm the valuable shipping business which had hitherto been transacted by Messrs. Wilson, Ritchie & Co. The crop of 1866-67 was a right good one, and so far all seemed to augur well for the new ventures of the Firm.

The sequel, however, may be best told by a few figures, shewing the

ANNUAL COFFEE CROPS

from that date of the estates owned by Keir, Dundas & Co., results arrived at, sad to say, in spite of consistently careful and liberal management.

	cwt.	
1866-67	36,135	} average 1st four years 32,170 cwt.
67-68	32,561	
68-69	29,268	
69-70	30,717	
70-71	24,133	} average 2nd do 17,996 cwt.
71-72	14,918	
72-73	21,215	
73-74 estimate	12,600	

In face of such results the game was manifestly a hopeless one in regard to the ultimate liquidation of the debt. The partners placed themselves in the hands of their chief London supporters, to whom after many months of anxious deliberation the whole business was transferred, both assets and liabilities, in return for a small cash payment. Mr. W. M. Leake returned home in September 1873. He remembers calling to say "goodbye to the Editor of the *Observer*," with the above figures in his pocket. The Editor (he tells us he saw Mr. John Ferguson and adds) "was then eagerly advocating the extension of the Railway to Haputale, using freely as an argument in its favour the probable increase of coffee crops." Mr. Leake on introducing his view that crops had hitherto only been maintained by the rapid increase of new land coming into bearing met with so much encouragement that he did not disclose the figures on which he relied, but contented himself with wishing the Editor good luck in his crusade!*[See further on as well as in note for Editor's justification.]

* In explanation, the Editor has to say that no one who knew the young districts in 1873 anticipated that they or Uva were to decline at any rate for a generation, as the old Kandy districts had done, and the figures for total crops of coffee will bear us out in this:—

Season	=	1871-2	cwt.	576,878
"	=	2-3	"	860,360
"	=	3-4	"	509,329
"	=	4-5	"	988,328
"	=	5-6	"	688,434
"	=	6-7	"	927,093
"	=	7-8	"	627,246
"	=	8-9	"	824,658

Needless here to dwell on the oft-told tale of the part taken by Mr. Martin Leake's Firm in introducing the cultivation of

CINCHONA AND TEA.

It is not so well known that a venture was made in

CARDAMOMS

in 1871 or 1872 on the suggestion of Major Taylor, a Wynaad planter, who came on a visit to Ceylon about that time full of the success of experiments recently made in South India. A beginning of this cultivation was made in Rangala, in the jungle between old Tunisgalla and Guindi Ella; and though at first the plants did not come on and the experiment seemed to be a failure, after some years of practical abandonment, they were found to be doing well and good crops were obtained. The cultivation has been continued and extended in certain localities in the neighbourhood with varying success up to the present time.

We have already referred to the part taken by Mr. Martin Leake in

PUBLIC AFFAIRS,

but we may add that from February 1863 to 1868 he was Secretary to the Planters' Association, in 1872-73 Chairman of the Planters' Association and M.L.C.; 1877 onwards London Agent of Planters' Association; 1888-97 Secretary Ceylon Association in London,—a prolonged record of connection with Ceylon planting, extending already over more than 34 years. As to details of work done are they not all written in Planters' Association proceedings and the pages of the *Ceylon Observer*?

No sooner had Messrs. G. D. B. Harrison and W. M. Leake retired from Keir, Dundas & Co., than a singular change came over the fortunes of

COFFEE.

The price rapidly rose 50 %, and many accounts, the position of which had seemed hopeless, were in the course of a few months restored to vigorous life. A notable instance was the account of the late Mr. G. A. Crüwell who had the good fortune on his Haputale estates,—now owned by Mr. Lipton,—to have in 1873 a fine crop on his coffee trees. It had been reckoned early in the year that the value of his properties ten short of the total debt on them by at least £10,000. Before the year was out Mr. Crüwell had sold the estates for £50,000 to the late Mr. K. B. Downall, had paid off all debts, and retired with a very substantial fortune, the balance of the purchase amount and of the proceeds of sale of the big crop sold at 120s. to 150s. per cwt. in London! Mr. Crüwell followed Mr. W. M. Leake to England in a very few months, summoned his friends to a sumptuous dinner to celebrate his good fortune, not least among his guests being his late Agent, Mr. W. M. Leake.

The "boom" in coffee in 1873 being brought about solely by the rise in price of the produce, was doomed to be shortlived so far as the value of Ceylon land was concerned. No enhancement of price could compensate for the falling-off in crops, and not many years elapsed before instances were frequent of collapses in the value of estates as sudden and as startling as was the prosperity that had attended Mr. Crüwell's venture. To mention an instance: in 1876 many estates had good coffee crops, prices were very high, and profits were very large. Among the rest Nilloomally, in Kelebokka Valley, gave returns stated at £6,000 to £7,000. It was currently reported that an offer of £40,000 was made for the pro-

perty and refused. The subsequent profits from the coffee on the estate can have been next to nothing.

Such were the ups and downs of fortune attending the last days of the reign of KING COFFEE.

TEA,

though it will surely have its bad as well as its good times, is hardly likely to be subject to the convulsive fluctuations of fortune that attended the downfall of coffee.

On retirement from Messrs. Keir, Dundas & Co., Mr. W. M. Leake hesitated as to his course in the future. His partiality for Ceylon and life there was finally overborne by family considerations; his elder children were growing up and continuance in Ceylon would necessitate separation for educational purposes. He determined to find work, if possible, at home. In 1874, co-operating with Mr. T. G. Wainwright, now Treasurer of St. Thomas's Hospital, he started the TUNNEL PORTLAND CEMENT WORKS CO., LTD., buying as the site for its operations a property of some 700 acres on the Essex shore of the Thames near Purfleet. The cement trade was at that time at the height of its prosperity. In common with nearly all productive industries in England, it has since come under changed conditions owing to the continued fall in prices. The fall in prices having been general without any compensatory fall in wages, shareholders in those industries, wherein labour forms a large proportion of the cost, have had to stand by while the position of the labourer has been year by year improved. In these circumstances it may be hoped that the good of the many, may in the long run prove to be the good of all, and that the wider diffusion of wealth, consequent on the economical position, may be surely, though silently, broadening the foundations of the prosperity of the United Kingdom.

Certain it is that demand in many branches has lately acquired a way of increasing by leaps and bound beyond all past experience. And though facilities for extending production are now-a-days such that no continuance of very high prices can be expected; yet in many depressed industries there have been of late signs of recovery and of a return even to the capitalists of a certain sober, healthy prosperity.

It is pleasant to add that Portland Cement, the leading industry of the Lower Thames and Medway, seems to be sharing in this revival.

Here, we leave the story of one of the best-equipped, most enterprising and most respected Colonists who ever laboured in Ceylon. The work of Mr. MARTIN LEAKE is by no means over: though in his 67th year—14 of those spent in the tropics—any one looking at Mr. Leake would take him to be at least ten years younger, and, humanly-speaking, his spare athletic form and vigorous constitution afford a guarantee for a number of years of usefulness; not least in connection with the Colony in which he has done such good and prolonged service. So note it be!

AUSTRALIAN ORANGE PLANTS.—Messrs. Thompson & Co. have imported a parcel of young orange plants from Melbourne to the order of some upcountry planters. The plants were sent up a couple of days ago and we hope to hear of their vigorous growth.—*Cor.*, local "Examiner."

INDIARUBBER IN THE HUKONG VALLEY.

[By H. N. THOMPSON, ASSISTANT CONSERVATOR OF FORESTS, BURMA.]

The India-rubber as found growing in the Hukong valley is not a gregarious tree. It appears scattered generally through the dense evergreen forests, but nowhere reaches the density per acre, say, of an average teak forest; occasionally a family group of four or five trees may be met with, but these are very rare indeed, and the usual thing is to come across a mature tree every 200 or 300 yards in the richer forests. The average of four valuation surveys made at the headwaters of the Namkong *chaung* gives 48 large trees per acre. *Ficus elastica* is essentially a light-demanding species, and though an evergreen and associated with and growing amongst dense shade-bearers no tree can be more exacting in its demand for light. Whenever it is surrounded with dense shade it will be found that this tree, in order to escape from it, has grown to enormous heights, in many instances towering head and shoulders over every other tree in its vicinity. Trees of great size were met on the upper slopes (3,000 feet) of the Loima hill at the headwaters of the Namkong *chaung*, and some of them were certainly the largest trees that I have ever seen of any species whatever. In accordance with its light-demanding character seedlings growing on the ground are extremely rare, and though I searched diligently for them on many occasions on the rich soil surrounding the parent trees (but covered with dense shade) I was never able to find one. The only seedlings seen by me were growing, as a rule, in the forks or crevices in the bark of light foliaged trees (*Dalbergias*, etc.) at a great height from the ground and occasionally on the half-rotten trunks of dead and dying plants in places where from wind-falls or otherwise clearings had been formed in the leaf canopy. The young seedling thus gets a good start over its rivals in the struggle for existence and grows rapidly up the stem of its host encircling the latter with its aerial roots and sending them downwards towards the ground till they form great supports on which the main trunk of the fig stands; meanwhile the host is gradually killed off and eventually disappears altogether, and the rubber tree is left standing on five or six or even more thick aerial roots. These roots often start from a height of 60 to 90 feet, and attain girths of from five to eight feet. The main factor determining the distribution of *Ficus elastica* seems to be an excessive humidity of the atmosphere. It appears to be able to accommodate itself to many varieties of soil (probably because its earlier stages are passed on a host) and to be indifferent, generally speaking, to rather large variations in altitude, though growing best at from 2,500 to 3,500 feet. The absence of a very high temperature would also seem to favour its growth, as the species is unknown from the otherwise suitable localities in Southern Tenasserim. However, this latter point may or may not be correct, and very likely the question may be complicated by the correlation of factors that we are not as yet cognizant of. But this much is certain, that it is found growing in abundance on the Loimaw hill at an altitude of 5,200 feet, and is reported from high altitudes in the Jan Mun Bun mountains to the east of N'tupusa and on the northern and southern watersheds of the Taron river, the higher crests and peaks of which are covered with large masses of snow in the winter. From what I could make out of the information given by the Singpho Chiefs of Ningbyen and N'tupusa, it does not appear to actually grow in places that are subject to snowfalls, but is found in all the deep, damp gorges on the slopes on such hills, very often creeping up the former to considerable altitudes. The winter snowline in the latitude of the northern portion of the Hukong valley (latitude 27° north) would appear to lie at least somewhere between 7,000 and 8,000 feet. As Colonel Woodthorpe and Major Macgregor, on their return

journey from the Bohr Khampti State, found it lying in large patches on the Chaukkan and Mokshat passes in April; these passes lie to the north-east of N'tupusa and are visible from Ningbyen; the heights are 8,450 feet and 7,000 feet respectively.

If the tree does actually grow high up the mountains on the north-east it must experience severe winter frosts, but it is probable that the influence of the latter is modified to a certain extent by the position of the seedlings on the stems of their hosts, and they very likely do not suffer to the same degree as they would if growing on the surface of the soil.

Mr. O'Bryen, in his report on the India-rubber forests of the Blamo district, divides those situated in the Hukong valley into the following areas, basing his classification on the routes by which the rubber is exported. As these divisions are convenient for the purposes of description, I will not disturb them. They are:—

(i) The tract north at the Tanaikha from its junction with the Taron river to a point 20 miles above Lagang village.

(ii) The southern basin of the Tanaikha from the Numgaung *chaung* down to a point 20 miles above Lagang village on the Tanaikha, excluding the sources of the Nampyu *chaung*.

(iii) The area drained by the Namkong *chaung*, north of Kamaing, including the sources of the Nampyu *chaung*.

(iv) The area drained by the Tanaikha south of a point about 20 miles above Lagang village and the left drainage of the Namkong *chaung* between Kamaing and Mogaung.

To this I will add, as No. VIII, the whole drainage area of the Taron river above its junction with the Gedu affluent, the greater portion of the India-rubber from this tract being exported to Assam, *via* the passes across the Patkoi range.

The protection of the rubber forests.—As before mentioned the Upper Burma Forest Rules relating to the tapping of India rubber trees appear to be a dead letter in the Hukong Valley and Namkong forests. And I have been informed by several Sawwas, such as Ningbyen and Nitumtumsa, that they are unable to enforce these rules or attempt to interfere in any way with the rubber collectors. Doubtless they have their own reasons for not interfering, as the more rubber that is collected the greater the revenue paid to them for it. So it is not likely then that in the absence of any means of enforcing the rule the latter will be attended to.

Regarding the Hukong Valley itself, I think we are powerless to protect the India-rubber forests by any legislative methods unless we are prepared to take the country over and administer it directly.

The Singphos are an exceedingly independent race, and at present *really* recognize no one as masters, under these circumstances, if we are not prepared to take over the country, and if we still wish to preserve the rubber forests from extermination, there is only one course left open to us, and that is to put a prohibitive tax on all rubber exported to the Myitkyina district from that valley. Of course there will be a great outcry from the Chinese firms engaged in the trade and from others, but unfortunately the choice of alternatives is very limited, and no half-measures are possible. The forests must either be completely protected or left alone; the Singpho would appreciate no other course of action.

I very much doubt whether the Hukong Singphos would understand very early why (in the event of a prohibitive tax being introduced) there would be no sale for their rubber. All they would concern themselves with would be the fact that there was no sale for it, and that therefore it was not worth collecting. There naturally would be a great falling off in the revenue, collected by the various Chiefs, and it is difficult to see in what way they could recompense themselves, and perhaps this is the most important objection to the introduction of such a tax.

The protection of rubber trees growing in forests situated within our sphere of direct administration, though a difficult matter where Kachins, (Singphos) are concerned, need not present any really serious

obstacles, and it is possible that if reserves are made of the richest areas, and the local Sawwas in whose jurisdiction the reserves would be situated were induced to interest themselves in the protection of the forests, and that the subordinate forest officials appointed to supervise them were selected from amongst some of the better class of Singphos, a great deal may be done towards the protection of this tree.

Work would be found for those who at present live on the proceeds derived from collecting rubber by getting them employed in the plantations.

Formation of rubber plantations.—For experience gained in Assam, it appears that it is quite possible to undertake the creation of rubber plantations on an extensive scale with a fair prospect of their supplying large trees in the future. Under these circumstances it would be advisable to start such plantations in the richer India-rubber bearing tracts on the lines recommended in Assam. Local Kachins could be employed for the work, which they would probably take to readily. Seedlings of the species are frequently found planted round the Kachin villages, but they do not attain the same dimensions as trees that have grown upon the forest.—*The Indian Agriculturist*.

CULTIVATION OF THE CHERIMOYA IN MADEIRA.

While on a visit to Madeira last autumn I was much interested in observing the extensive cultivation of the Cherimoya (*Annona cherimolia*) which is now being carried on there for the London market. Many of the estates on the warm southern slopes of the island, formerly covered with vineyards, have now been systematically planted with the Cherimoya, the sheltered valleys being particularly suited for them, the trees attaining a height of 30 to 40 feet and bearing abundantly. Propagation is by seed only. The young trees are grafted when about two years old and begin to bear about three years afterwards. When the leaves have fallen in May the trees are pruned, only those branches which are likely to bear fruit being left. On some plantations the young trees have been topped when about eight feet high and the laterals trained along horizontal espaliers with excellent results. The trees are in this way brought under thorough control, can be easily pruned and the fruit thinned out. Stable manure is usually dug into the ground over a considerable area around the trees in the early spring months. The crop is gathered in December and January. As the result of cultivation several improved varieties of the Cherimoya have been obtained bearing fruits with hardly any seeds and in which the fleshy eatable part is largely increased in quantity. The fruits vary in weight between three to eight lb., exceptionally large ones may reach 16lb. and over. The maturity of the fruit is indicated by the loosening of the seeds inside which may be felt when the fruit is shaken. They are still quite hard to the touch but fit to pick and if laid in straw will rapidly ripen. The fruit is always cut off the tree with a sharp knife leaving a short stalk attached; if it is pulled off the core is injured and the pulp spoiled. Special boxes are made for packing the fruit which are first wrapped in paper and then embedded in straw; each box holds about two dozen fruits. The journey to London generally occupies four days. On arrival they are unpacked and placed on shelves in a warm room where they quickly ripen. Average-sized fruits usually fetch from six shillings apiece, larger ones 10s. and more. The Cherimoya grows well in the mountains of Jamaica. Fairly good fruit is not uncommonly brought into Kingston for sale. I venture to think that it might be worth while to bestow more attention on its cultivation in view of the possibility of getting the fruit to London in good condition in cool chambers. The Cherimoya is rightly acknowledged to be one of the most delicious of tropical fruits and there is no doubt that shortly the demand for it will increase very greatly.—*Journal of the Jamaica Agricultural Society*.

Kingston.

M. GRABHAM.

TEA PLUCKING AND IRREGULARITIES IN TEA.

We must tell Mr. John Hamilton that the general consensus of opinion both in planting and mercantile circles in reference to his letter is that to abandon "refiring" would be a great mistake. In the moist climate of Ceylon, it is simply indispensable; but it is evident that more care must be taken in regard to both "bulking" and "packing" in not a few factories in our tea districts. At the same time when Mr. Hamilton speaks of "all the selling brokers employing a highly-paid expert to inspect the teas placed in their hands," exception is taken and one gentleman here who knows "all about tea in London" declares the inspection is left to quite a junior—an assistant in his second year usually.

Now as regards the need of special care in estate factories, we have had evidence put before us of very recent experience of irregularity in regard to the teas of well-known Ceylon estates which never sell in Colombo. In all, four cases are adduced as occurring within a few days and all telling against "Ceylons." For, it is alleged that in regard to Indian teas, there is no trouble: on the catalogues of the latter "bulked in London" is now being printed. We fear it must come to this in respect of "Ceylons," unless each proprietor, who wants to sell in London, insists that special care is taken in his factory as to bulking and packing, due supervision being provided for the same. It is impossible that a Superintendent by himself can see to all the work in the field as well as in the factory. There ought to be a run therefore on careful Factory Assistants, who should be made to understand the penalty attaching to irregularity in bulking, to bad packing, difference in gross fares, or above all to using "cheesy" or bad boxes!

LAND ON THE ANAMALAI HILLS.

To the Editor, Madras Mail.

Sir,—I see that Government Notices appear in the *Madras Mail* and in *District Gazettes* that "about 80 square miles of land on the Anamalai Hills, in the Coimbatore District, are available for application for planting purposes under the subjoined rules." This would be say 50,000 acres. There is, no doubt this quantity "available," but I say without hesitation that the quantity *suitable* for tea or coffee cultivation is represented by a far smaller area. As I am the only one of the original applicants as yet who has begun to open out those hills, I may claim to be interested in their future welfare and development, and neither of these will be served if unsuitable land is taken up and money spent upon it. A new District has to make its reputation and a bad start takes a long time to get over; I trust therefore that any who think of taking up land there will use the utmost care in its selection. As I may now claim to have some little experience of the place, the following facts may be interesting. Health is very good, contrary to the alarmist ideas freely expressed. Fever is practically absent (and I am speaking of the worst time, from beginning of February to breaking of monsoon) both with Europeans and natives; I should say that, man for man, there is less fever than on an ordinary healthy hill estate, though it was not in other places a healthy season this year. The climate is very remarkably even, owing no doubt to the

mass of evergreen forest. Wind, before and during the monsoon, is absent on well-selected land, though I should be sorry to have much of the 80 square miles, on this account. I have been there also during the N.-E. monsoon and should say that no one selecting land carefully need get wind at any time of the year. The rainfall is probably abnormal this year, judging from the facts that Cochin and Calicut are many inches over their average to date, and that S.-W. rain at these places has, on every occasion this year, meant rain on the Anamalais, though in far less quantity at the latter place. As I have only had a rain gauge in position since the beginning of February I cannot yet say for certain what the result will be, but from results to date and what I have observed when there in September and November, I am inclined to forecast an average rainfall of something under 100 inches, heaviest in June and July but with a good N.-E. fall and enough in earlier months to ensure setting blossom (this year the fall from February to June was 11 inches 18 cents). Labour, of course, has all to be imported, and I may mention that the greater distance it is brought the better; labour from the small villages round the foot of the hills is of little use. Felling costs far more than in most districts, the forest being very heavy; pitting would be easy, but for roots, the soil being a sandy loam of great depth, with perfect drainage. I should mention that my remarks on health refer to an elevation of 4,000 feet, where I have my buildings, the clearings being a couple of hundred feet lower. I have no doubt of the future of the Anamalais as a planting District if care is taken at the outset, and it is to that end that I would speak a word of warning against indiscriminate selection of land while there is yet time. Every district has suffered from it. Experienced planters are the men first wanted in a new District, and I hope that is the only class which will attempt to settle there to begin with. A good bridle path is now open into the forest, passes my door, in fact, but I do not think the line of the bandy road promised by Government is settled as yet.

Kotagiri, 30th July.

E. G. WINDLE.

NOTES FROM MAHÉ, SEYCHELLES.

VANILLA

The beans resulting from last year's flowering have nearly all been gathered, and are in course of preparation. Although much smaller than the previous year the crop generally will be a fairish one so far as is yet known. In the lower parts of the island the first flowers of this season are commencing to appear.

Apart however from Vanilla and its attendant uncertainties as to crop and price, there is an increasing source of productiveness here in *Liberian Coffee*. A good deal has been done in planting out of late years, and although slow of growth at first, the trees once established are flourishing well, and many can be seen here now of 4 and 5 years' growth, pictures of health and beauty and in full bearing.

H. T.

THE KELANI MILLS.—The mills were opened recently, and desiccating works is in full swing now. Besides this work, the mills are manufacturing coconut fibre for various purposes. As a result of the opening of the mills a large number of villagers have found work to keep them from idleness.—*Cor.*

SIR GREME ELPHINSTONE ON THE PLANTING PROSPECT OF PERAK.

"This will be a grand country in 20 years. Coffee Liberian, coconuts and rubbers; cattle feeding also will pay well. Somehow or another one always feels in touch with Ceylon here. So many of the Civil Servants and Planters have been and are associated with Ceylon either by relationship or business. Then in the lower grades of the Civil Service all departments and especially in the medical are recruited from Ceylon.

"I never look on this country except as having a sort of consinship with Ceylon and that together they will help to supply a large proportion of the world's requirements.—GREME ELPHINSTONE."

PROSPECTS IN NYASALAND. INTERVIEW WITH MR. ALEXANDER WHYTE.

Mr. Alexander Whyte, the well-known botanist and naturalist, formerly head of the Scientific Department in the Administration of British Central Africa, has just been in Aberdeen for a few days, on his way through to Braemar, where he intends spending a well-merited holiday after his arduous exploratory and scientific labours in Nyasaland, of which some account has already appeared in these columns. Mr. Whyte is looking hale and hearty, and none the worse of his experiences in British Central Africa, where indeed during all his stay of six years he has enjoyed exceptionally good health, having never been once down with fever. The collections which he has made of the dried plants and of the birds and the animals of the country are very extensive—among the most extensive made by single scientists it is believed—and the authorities at Kew and at the Natural History Museum in Cromwell Road are highly pleased with the results. The Zoological Society have rewarded Mr. Whyte by presenting him with their medal in regard for the value of his investigations. Mr. Whyte speaks in glowing terms of the progress made in this Protectorate, now our newest Crown Colony. A review of what has been done during the past half-dozen years is truly astonishing, and it would be difficult to point to such a record of work effected for anything like the same expenditure of money in any other country or colony. The very tribes who were the most hostile and the most obstinate to submit to British rule and to abandon their slaving propensities are now furnishing the best recruits for the military and police forces. The revenue is increasing by rapid strides, and nearly all the tribes are willingly paying the tax of 3s. levied on every household.

Of the wonderful

NATURAL CAPABILITIES OF BRITISH CENTRAL AFRICA

Mr. Whyte is well qualified to speak. The most serious obstacle to the rapid development of the country, he says, is the want of easy and cheaper means of transport to and from the coast. Fortunately, however, this is to all appearances about to be remedied. A railway survey from Chiromo, at the junction of the Ruo and Shire rivers, to Blantyre has been most efficiently completed and laid down on a large scale by Mr. Macrone, who is now home in Edinburgh, with all the requisite details and information to lay before his directors. Britain in self-protection must push it on, so as to secure for herself the

most advantageous highway, *via* the Lakes, into and through Central Africa. Between the sea and the terminus of the proposed line at the Ruo and the Shire rivers, the Zambesi river steamers provide a transport, but the railway which the Portuguese are making from Quilimane to the same point will in a short time provide more convenient and quicker communication.

Of the prospects for

COFFEE

—the staple of the country—Mr. Whyte speaks in a very hopeful way. The soil and the climate are quite suitable. Mistakes have naturally been made through the want of experience. The coffee bush requires special treatment, and it does not follow that what suits it in one country will be equally successful in another. Hitherto the coffee planting in Nyasaland has been in a measure passing through the experimental stage. Now, however, the treatment of the coffee, especially as to shade, is better understood, and crops, paying very fairly, are being picked. The transport question once solved, land for coffee planting would, Mr. Whyte feels sure, be taken up on a large scale.

Among the other products likely to prove remunerative in British Central Africa Mr. Whyte considers the next best to coffee to be

RUBBER,

which is indigenous in the land, and the demand for which in the world of commerce is continually increasing. The *Landolphia*s, the best yielders of rubber, are growing in Nyasa, ready to be tapped in the native state. Samples of the rubber from this plant Mr. Whyte gathered and sent home to this country. His idea of how to cultivate the rubber trees would be to plant them in forests at the foot of other trees, which would serve as stakes up which they could climb. This would be an inexpensive method of establishing forests of rubber, and the only drawback is that it would entail the locking up of capital for five or six years before yielding a return. The Ceara rubber also grows freely in the Shire Highlands, but it has not been found productive enough to pay. Another product which has already been introduced, and which promises well in the lower and hotter districts is Liberian coffee, while cardamoms, nutmegs, and spices might also be grown to advantage. Cacao Mr. Whyte has tried to introduce on several occasions, but without great success. The cacao plant is very delicate and difficult of transport, but Mr. Whyte feels confident that there are many suitable localities along the banks of the rivers and in the mountain ravines where it would do admirably if once started. As to cotton, it could be grown to a boundless extent, but the cost of conveyance is at present killing to this branch of agriculture. Tapioca has been manufactured to a considerable extent by the members of the Established Church Mission at Domasi from the roots of the manihot or cassava plant, and has proved of excellent quality, finding a ready sale among the Europeans of the district. Arrowroot could also be cultivated, and in fact nearly all tropical and sub-tropical economic plants could find suitable habitats in Nyasaland. Stock of all sorts thrive well on the plateaux of west and north Nyasa. Cattle are now plentiful with the planters, supplies having been got from Tete, on the Zambesi, and from Angoniand, to the west and southwest of Lake Nyasa. Goats and fat-

tailed sheep are everywhere abundant. European sheep have as yet proved a failure, their fleeces being rendered all but valueless by the quantities of seeds and burrs which become entangled in the wool.

As to the

HEALTH OF EUROPEANS

in British Central Africa, it cannot be said to be good. There is little danger to be dreaded from the ordinary malarial fever, but unfortunately a bad type, called black-water fever, sometimes crops up, and a good many valuable lives have fallen victims to it. Mr. Whyte, however, believes that a great improvement will come about when the country is opened up and more comfortable houses and surroundings become available. He remembers well when some of the West India islands and Ceylon were quite as unhealthy. Now they are in some cases being visited as health resorts, so salubrious have they become. In Nyasaland, the services of a staff of experienced and skilful doctors sent out by Sir Harry Johnston are now procurable, and Dr. Kerr Cross, formerly of the Livingstonia Free Church Mission, and Dr. Grey, of Portobello, have just sailed to join the Administration. The work recently completed by Dr. Cross on "Health in British Central Africa" will form an excellent guide for young men emigrating. It is all important in Nyasaland, as in all tropical countries, to know how to live, and a man's health greatly depends upon himself, whether he uses judiciously or abuses his constitution. Temperate yet active habits, with a well-balanced, cheerful, and equable mind, backed with a good thick stratum of common sense, are golden possessions out in Africa, where many trials and worries have to be encountered. Mr. Whyte describes with regret how practically the whole trade of the East Coast of Africa from Delagoa to the Red Sea has passed out of British hands through the enterprise of foreign, and especially German competitors.

Asked his opinion on the

MISSIONARY QUESTION,

Mr. White has no hesitation in saying that missionaries have been a great power in the land in influencing the natives. A great deal has been said of missions of late, and it is very easy, and so far legitimate, to criticise public bodies. Unfortunately, however, missions frequently undergo very unjust criticism. Of the work done by Dr. Laws and the free Church Mission Mr. White speaks in unqualified terms of praise. It is, he says, perfectly astonishing to witness the hold Dr. Laws has on the people and the influence he exercises over them.

Mr. Whyte's last

EXPLORATORY WORK

before his present return home was done in the Masuka Mountains, on the German boundary to the north-west of Lake Nyasa. Here he found a most interesting race of people. They were very shy and suspicious, and although he sent scouts and guides with presents to attract them, it was days before he got into touch with them. When he at last succeeded in getting the chief and some of his headmen to visit the camp and in gaining the confidence, of the people, he found them a most kind, docile, and tractable race, a branch of the Wankondi. The chief and his headman invited Mr. Whyte to come and reside with them and be their Chief. They promised to carry

timber for him and build a house if he would only settle with them and plant coffee. They are extremely cleanly and tidy in their habits, and their villages, which were well stocked with cattle, sheep, and goats, were patterns of tidiness. Mr. Whyte was more than surprised to find that public latrines, neatly constructed and screened off from sight, were in universal use throughout the villages, a striking contrast to the tribes further south, on whom it is very difficult to impress the value of sanitary measures.—*Aberdeen Free Press.*

TORTOISE-SHELL.

Mr. Frank S. Smith writes:—A good deal of the world's supply of tortoise-shell comes from the Solomon Islands. The term 'tortoise-shell' is one of many misused terms in common use. The shell is not obtained from the tortoise, which is a land animal, but from the hawksbill turtle, an inhabitant of the sea. All of the turtle family that I have come across are shellbacks, but, with the exception of the hawksbill, the shell is practically valueless. That of the hawksbill turtle is dark brown when on the back of the animal, and bears very little resemblance to the burnished and beautifully-mottled article seen in shops. It is not until the shell is cleaned and polished that the dark spots appear. The turtle from which the shell is taken lives in the sea just off the Solomon Islands. It varies in size greatly. I have seen them weigh up to 4 cwt., when it required the united strength of four men to overturn one. The female turtle comes up out of the sea at nights, especially when it is moonlight, to lay her eggs on shore. This is the time, and the only time, that the natives are able to catch turtle. They go in groups to the shore where experience has taught them to expect the turtle, and they wait silently in the grass undergrowth till the animal appears. Presently a broad dark form is seen moving slowly, laboriously, and cautiously from the water's edge up the sandy beach. It stops every now and then, and at last finds a spot suitable for depositing eggs. The natives at once rush out, get hold of the shell, and before the unfortunate wanderer knows what is the matter they give one simultaneous heave and it is lying helpless on its back. Unless they overturn the turtle they could not prevent it from forcing its way back to sea. Blows on the back would injure the shell and not incommode the turtle greatly. When the animal is on all-fours the head is concealed, and it is impossible to get at the legs. Once on its back it is powerless. The natives tie the legs firmly together, and, after tethering it by a rope, put the turtle right side up again. A burning torch of resinous bark is obtained and passed up and down the back till the heat releases the shell. The shell is not in one whole piece, but consists of nine parts, which overlap like fish scales. The heat loosens the joints, and the pieces are then pulled off. If the islanders have plenty of food, the turtle is then released, when it goes off to sea in a bruised and painful condition, and sets to work to grow a new shell. But the new shell is of no commercial value, being thin and colourless. More often the turtle is killed and its eggs abstracted and eaten. It is only at spawning time that turtles come to land, and only the females come then. The shell is worth up to £1 15s. per lb. in London, and up to £9 worth is sometimes obtained from one turtle. As a small tortoise-shell comb costs £1 5s. or thereabouts, it may be believed that most of what we see exposed is imitation.—*Western Star, Aug. 1.*

CREEPERS IN SOUTHERN INDIA—seem to be able to manage more economically than in Ceylon when we are told—see letter in our *Tropical Agriculturist*—that "while R100 a month is better than "R75 and R75 than R50, no man need starve or "even stint himself if he has R50 a month to his "name."

COCONUT PROPERTY IN CEYLON.

VALUE OF COCONUT PROPERTY.—No doubt the respective merits of the plantations sold yesterday justified the wide difference between the prices paid. For Letchimey estate, 248 acres, in the Chilaw district the price paid (R162,000) works out to nearly R660 per acre; while for Setavana estate 100 acres in the Puttalam district, the rate is just one-half or R330 per acre, the price being R33,000. We suspect that the popularity of the Chilaw district had a good deal to do with the difference.

A merchant writes:—

"Your reference to the sale of Letchimey and Setavana coconut estates, in issue of 12th inst., is surely based on insufficient information. The two estates are within a mile of each other." This has reference to our finding an explanation of the one realizing double the price of the other per acre, in the one estate being described as situated in Chilaw, and the other in Puttalam district. We now understand that there was some reason for the lower price not connected with the coconuts, soil or situation.

We lately mentioned that Aspokunawatte, the property of Mr. Melville White, in Kurunegala district, had been sold. The purchasers (or their Agents) are Messrs. Finlay, Muir & Co., and the price paid is R48,000 for a total area of 365 acres, of which fully 200 acres are planted with Coconuts and some Cacao and Liberian Coffee. This ought to be a bargain for the purchasers if the palms do well.

THE TREATMENT OF TEA IN THE LONDON WAREHOUSES.

(To the Editor of the *Home and Colonial Mail*.)

Sir,—It seems to me that the time has come for the Indian Tea Association to take up the question of the proper re-packing of tea in the London warehouses. The objectionable method at present in vogue has been repeatedly shown up in the English and Indian press, in public lectures on tea in representations to the Association itself, and in the elaborate work on tea lately published. So far as we tea planters know only one warehouse has thus far shown itself open to improvement, and has brought in modern machinery to replace the rough docker's boot for pressing in the tea.

Anyone who has seen the present barbarous method in operation will, I am sure, agree with me that it is unworthy of the present century, and to an Indian or Ceylon planter who has been used to the utmost care in packing teas it is simply shocking.

If something is not done soon to improve matters the question will find its way into the magazines and daily papers, and we will have illustrations showing a heap of tea being shovelled into chests, and a row of dockers jumping upon it and stamping it in with their boots. It is a disgrace to civilised methods.

The question of cost is no doubt a great factor in all improvements, and the warehouse authorities seem to have thus far overlooked the fact that by using machinery they would probably save the cost of half a dozen men by each machine put into use.

As a planter I am anxious to push the subject, because I find that by using machinery I can get more tea into a chest, and thus effect a considerable saving in cost of packages and transit; but then I tremble for our fine teas when they come under the heel of the ruthless docker, for if ordinary stamping is not sufficient, such violence will be used that there will be nearly as much dust as leaf when the chest comes to be opened by the grocer.

Another point which urgently needs to be dealt with is the manner in which the chests are closed up after re-packing; the shreds of torn lead being merely laid on the top and the lid roughly nailed down. Sometimes a bit of brown paper is added if the lead is in a very bad state. Why should not the packages be properly soldered up?

The Indian branch of the Tea Association has recently had a committee to inquire into the treatment which packages receive in Calcutta. Why should the Association in London continue to countenance and perpetuate a crying evil which causes a continual loss to all concerned and practically ruins a large proportion of our finest teas?—I am sir, yours, &c., ANXIOUS PLANTER.
—*H and C. Mail*, July 30.

THE CONSOLIDATED TEA AND LANDS COMPANY, LIMITED.

The following is from the report for the year ending 30th November, 1896, to be submitted to the first ordinary general meeting of shareholders of the Consolidated Tea and Lands Company, Limited, to be held in the Accountants' Hall, 106, West Nile Street, Glasgow, today (Friday):—

The directors have pleasure in submitting the accounts for the year ending 30th November 1896. The season, as a whole, has been favourable, the total crop having amounted to 10,620,520 lb., against an estimate of 10,416,573 lb. The average price obtained was 7.67d per lb. The season's operations have resulted in a profit of £112,228. 15s., to which has to be added the profit derived from the sale of land in Travancore, viz., £63,152 4s.—in all £175,380 19s. Against this sum the following amounts are chargeable:—Commissions on profits to managers of estates, managing agents in Calcutta, and secretaries, £11,150 7s.; interest to shareholders and others on deposits, £1,039 3s 5d; interest on purchase price payable to the North and South Sylhet Tea Companies, Limited, £55,811 11s 9d; dividend paid to the first preference shareholders of the company, £12,912 4s 10d; dividend payable to the second preference shareholders of the company, £7,231 6s 8d—leaving a balance of £87,236 5s 4d to be dealt with. Out of this the directors propose to pay a dividend of 10 per cent on the ordinary shares, which will absorb £8,000, to place the sum of £65,000 to a reserve fund, and to carry forward to next year a balance of £14,236 5s 4d.

The latest reports from the company's visiting agents and superintendents show that the estates are in good cultivation, and that the estimates of yield for the current season, viz., 11,486,300 lb., will probably be realized. During the year under review 4,827½ acres in India and Ceylon have been cleared and planted. Of this area, 4,118 acres have been planted with tea, and 679½ acres with cocoa, coffee, and coconuts, bringing the total planted area up to 32,257½ acres. A further area of 4,337 acres will, it is hoped, be planted in 1897, chiefly in Assam and Ceylon.

As mentioned in the circular of May 21, 1897, to the shareholders, the directors have concluded an agreement with the Amalgamated Tea Estates Company, Limited, to work the whole of this valuable property on joint and equal account. It was the original intention of the directors either to sell portions of the company's property or to form various subsidiary companies, but further experience in developing it showed them that the introduction of competitors would probably tend to enhance the rates of labour considerably, and otherwise add to the cost of cultivation. It was therefore arranged to form the Kanan Devan Hills Produce Company, Limited—the shares to be held by the Consolidated and Amalgamated Companies equally—to purchase the land and estates of the company in the Travancore Concession for £146,525, being the valuation arrived at after careful inspection, by Mr. William Milne and Mr. Leyburn Davidson. This has accordingly been done; and this arrangement, while preserving the advantages of one proprietary, secures the necessary capital for the rapid development of the

undertaking. With regard to the proposal to sell four of the company's Ceylon properties to a subsidiary company, the directors have decided not to dispose of these meantime. As to the amalgamation of certain other of the company's estates in Ceylon with those of a neighbouring company, the Consolidated Company have now concluded an agreement to amalgamate their holdings in the Bambarabotua Valley with those of the East India and Ceylon Tea Company, Limited, in that district. The properties of both companies will be valued by Mr. Joseph Fraser, tea planter, Matale, Ceylon, and taken over by the new company, to be called the Hopewell Tea Company, Limited, which has been formed to work the amalgamated group, as from September 15, 1897. The shares in the new concern will be held as to two-thirds by the Consolidated Tea and Lands Company, Limited, and as to one-third by the East India and Ceylon Tea Company, Limited. This amalgamation will lead to greater economy in working, and consequently to more profitable results.

The directors have to advise the purchase of the Soongachi, Oodlabari, and Gajilidnbah Estates, situated in the Doora, for the sum of £16,000. Soongachi lies midway between two of the estates taken over by the company from the North Sylhet Tea Company, Limited, and as the three properties practically make one division, considerable economy in working will result from their being under one superintendent. The Oodlabari and Gajilidnbah estates having been grouped with Soongachi at the auction sale, had to be bought along with the latter property, but as they were not favourably situated for being worked economically with the other estates of the Company in that district, the directors decided to sell them on the first favourable opportunity. This occurred last January, when the price of £32,500 was obtained for them. Since the close of the financial year, the directors have also bought the Kumla estate, Doora, for £270,000. This garden lies between two of the Company's properties, and its acquisition will lead to more economical working on the Dam Dim-Division. The directors propose making a call of £1 per share on the ordinary shares, payable in September.—*H. and C. Mail*, July 30.

COFFEE COMPANY'S REPORT.

THE DUMONT COFFEE COMPANY, LIMITED.

The following is from the report presented at the second ordinary general meeting:—

The profits for 1896 were guaranteed by the vendors at £120,000. This sum was duly paid to the company, the appropriation of same being as follows:—Expenses to December 31st 1896: In London, £2,278 11s 7d; in Brazil, £754 16s 1d. Less amount of interest and commission, £851 5s 1d; writing off the entire preliminary expenses, £3,327 2s 3d; interest to December 31st, 1896, on the five and half per cent. first mortgage debentures, £5,100 15s 11d; dividend to December 31st, 1896, on the seven and half per cent. cumulative preference shares, £6,109 14s 9d; dividend to December 31, 1896, on the ordinary shares at the rate of 10 per cent. per annum, £8,145 16s 5d; interest on pre-payment of calls, £199 1s 9d; amount placed to reserve account, £83,506 17s; amount carried forward to 1897, £11,411 9s 4d; total £120,000. The actual profits of the Companhia Agricola Fazenda Dumont for 1896, after providing for all outstanding on the estates, amounted to £2,444,024,694, which sum calculated at the average rate of exchange ruling throughout the year, is equivalent to £92,605 12s 5d sterling. This short fall in the profits is mainly attributable to the heavy drop in the price of Santos coffee, and to want of care and supervision in the harvesting and curing of last year's crop owing to the ill-health of the vendor's manager. A large difference arises, moreover, in the conversion of the profits into sterling at the average rate of exchange for 1896, as against the rate at which the auditors based their estimates in the prospectus. The crop, which had been calculated at 80,357 cwt,

amounted to 74,115 cwt. Your directors were not in a position to exercise any control over the management of the property until January 1st last. Since then steps have been taken to introduce a better system of management and to add considerably to the machinery and appliances for curing the coffee crop. A considerable quantity of new machinery has been purchased, and some of it is already erected and in working order on the estates. The benefit of these improvements will only be partially felt during the current season, but when completed they will undoubtedly materially improve, the quality of the coffee and consequently the prospects of the company. The directors have further engaged a gentleman of experience, who will shortly proceed to Brazil to thoroughly examine and report on this machinery, and to advise regarding future requirements in this direction. The lands planted with coffee, stated in the prospectus as being about 13,000 acres, have now been surveyed, and are found to cover an area of 13,461 acres, of which about 9,800 acres are in bearing and 3,661 not yet in bearing. Latest advices from the managing director show that the estates are in a satisfactory condition and more labour had been obtained. Seven pulpers have been at work day and night on this season's crop, against only two last year, and the new machinery is being erected and gradually brought into working order. The reports and valuations received to date on this pulped coffee are of a most satisfactory character, and justify the expectations of the directors. Three Englishmen have been appointed to assist in the management of the estates, and two of them have already taken up their duties. The company's railway, which is being extended, has recently been favourably reported on, and is now in good working order. The properties have been duly transferred and mortgaged in favour of the trustees for the debenture-holders in accordance with the law of Brazil. The vendor company, viz., the Companhia Agricola Fazenda Dumont, the shares of which are held by this company, has been kept in existence for convenience of working and in order to maintain its local and trade relations. A Stock Exchange quotation has been duly granted for the debentures, and both classes of the company's shares. Mr. C. A. Carlisle, late of Sao Paulo, has joined the board of this company, while Senhor Cornelio Procopio, owing to failing health, has been compelled to resign the management of the estates, which is now undertaken by Mr. John Buchanan, a director of the company, assisted by Senhor Bourgas. It is hoped that an interim dividend on account of season 1897 may be paid on the ordinary shares in October next, by which time the amount of this year's crop will be known and a large quantity of it sold. As far as the directors can see, the accounts in the future will be closed, so as to admit of the annual general meeting being held in London in the month of April.—*H. and C. Mail*, July 30.

AMERICAN DOMESTIC TEA INDUSTRY.

There has been no question that tea can be grown in certain parts of the United States, nor that it has been successfully grown in South Carolina. The labour problem has stood in the way. South Carolina cannot compete with cheap labour in the Orient. Machines have not yet been invented to pluck tea, and until that day comes domestic grown tea will not figure in the American market, except as a curiosity. There is also a deficiency in rain fall to operate against the successful growing of tea in the United States.—*American Grocer*, July 14.

INDIAN PATENTS.

Applications in respect of the undermentioned inventions have been filed, under the provisions of the Inventions and Designs Act of 1888, in the office of the Secretary appointed under that Act, during the week ending 24th July 1897:—

Improvements in Transplanters.—No. 61 of 1897.—George William Clarice, planter, of Harehatch Estate,

North Travancore, for improvements in transplanters, or implements for transplanting plants and shrubs. (Specification filed 15th July 1897.)

Improvements in apparatus for Drying Tea, Grain, Hop.—No. 277 of 1890.—Samuel Cleland Davidson, merchant, of Sirocco Works, Belfast, Ireland, for improvements in apparatus for drying tea, grain, hop, or other substances. (From 13th August 1897 to 13th August 1898.)

Now ceases:—Improved method of and means for the Drying of the leaves of Tea.—No. 302 of 1892.—Lionel Maynard Torin's invention for an improved method of and means for the drying of the leaves of tea and other plants. (Specification filed 19th April 1893.—*Indian and Eastern Engineer*, August 7.

VARIOUS PLANTING NOTES

THE PROSPECTS FOR THE FRUIT SEASON.—says the Acting District Officer, Ulu Langat (Mr. O. F. Stonor), in the *Selangor Government Gazette*—owing to the long-continued rains, are extremely bad, and the durian crop promises to be the worst experienced for many years. On the other hand, a larger area of padi land is being brought under cultivation than was the case last year, planting being fixed to take place in about three weeks' time.

COLONIAL RUBBER ESTATES, LIMITED.—Capital £100,000, in shares of £1 each. This company has been formed to acquire certain territories on the West Coast of Africa, with the sole right to cultivate, gather, and trade in india-rubber from such territories. The purchase price is £80,000, payable as to £30,000 in shares, £10,000 in cash, and the balance of £40,000 in cash or shares, at the company's option, thus leaving £20,000 for working capital. We do not at all like the look of this company, which we should advise investors to avoid.—*Daily Chronicle*, July 27.

RUBBER CULTIVATION by the Ceylon Forest Department has not come to much as yet. Here is the Report for 1896:—

Province of Sabaragamuwa: Edangoda and Yati-powa Rubber Plantations.—No further additions were made. The para rubber trees show a most decided growth, especially in the flat portions above flood level where wash is not felt. I do not think that it is yet time to tap the dominating trees, but a beginning might be made with the suppressed trees, which will probably not yield much, as the ratio of yield of small trees is much smaller than that of large trees. The experiment with jak on poor chena land near the above plantations cannot be considered a success, especially as the plants suffered from attacks of porcupine and mouse deer. The expenditure of the year amounts to R361.79, and the receipts to R24.

THE GROWTH OF SISAL HEMP continues to promise profitable results as a fence plant in the Deccan and as a crop adapted for the most exposed positions on the Western Ghats, under a heavy rainfall. A single offset planted out three years ago at Khandalla, where the rainfall is excessive, has now leaves 4 feet in length; it is planted in stony soil and has not received special culture. A plantation of 170 young offsets has been made near Nandgaon on the crest of the Western Ghats, 12 miles south of the railway station at Lonavla. A quantity of Sisal fibre has been prepared from the plants grown at Poona and despatched to Kew for the opinion of experts regarding its value. The rope makers in this neighbourhood say the fibre is very much stronger than that of *Agave vivipara* which the plants greatly resemble.—Mr. G. Marshall Woodrow, Lecturer in Agriculture and Officer in charge Botanical Survey, Bombay.

THE TROPICAL AGRICULTURIST: A COMPLIMENT.—An upcountry planter who never wrote on the subject before, says in the course of a letter received today:—"For a planter I know of no such useful work as the one you monthly produce, and I for one am grateful for the reliable information it imparts."

SLEEPERS ON THE RAILWAY.—This is what the Engineer of Ways and Works has to say on this subject in his last year's report:—

Sleepers.—The use of doon, kumbuk, na, and other native wood sleepers that have been supplied by the Forest Department is not economical, as the average cost is R4 each, and the average life four years, while creosoted pine sleepers from the Baltic ports cost R3.69 each, and have an average life of eight years; but if the Forest Department could supply satinwood sleepers at a reasonable cost, they would be very valuable, as they have an average life of twelve or fifteen years.

Australian ironbark (one of the eucalypti) has proved to be very serviceable for sleepers, as it has an average life of eighteen years in Australia and England. It would be advantageous to ascertain if equally good results could be obtained here.

PROSPECTS IN NYASALAND.—On page 232, will be found the summary of an interview with Mr. Alex. Whyte, so well-known in Ceylon, on the above subject taken from the *Aberdeen Free Press*. Mr. Whyte speaks in a very satisfactory, not to say jubilant tone. Certainly Central Africa has done well for him. Remembering Mr. Whyte's age, and his comparatively poor health latterly in Ceylon, nothing has surprised us more than his great success as a pioneer botanist, explorer, collector and agricultural adviser in Central Africa. If Nyasaland is so unhealthy as some men say, how is it that Mr. Alex. Whyte has done so much there without apparently suffering in health? It is clear, however, that further development of the settlement must be slow until the much-needed railway is made.

THE TRADE OF THE PHILIPPINE ISLANDS.—Mr. Rawson-Walker, our Consul at Manila, states in his last report on the Philippines that the islands number about 1,200 and have a population of over 7½ millions, including 100,000 Chinese. The chief industries are all in the hands of the latter, of whom about 50,000 live in Manila alone. Next to Manila the chief centres of trade are Iloilo, in the island of Panay, and Zebu, where some of the chief British merchants of Manila have branch houses. The protective tariff which came into force in 1891 has caused a large and steadily increasing quantity of trade in cotton goods and yarns to be diverted from the United Kingdom to Barcelona, the chief loss being in the stouter piece goods and in yarns. The trade in fine goods still remains with the United Kingdom, as Spanish manufacturers have hitherto failed to produce cloths made of the finer counts at reasonable prices. For some years past the hardware trade has been gradually passing out of the hands of English firms to German and Swiss houses, so that now the latter have almost the sole importation of all classes of iron and its manufactures. Last year an increased scale of export duties, was put in force with only 24 hours' notice, to the great injury of the trade, and especially of the staple exports, sugar, hemp, and tobacco. The wealth of timber in the islands is incalculable, and it yields resins, gums, mastic pastes, dye products, fine grained ornamental woods, and heavy wood for building. The value of the sugar exported last year was £1,600,000, of the hemp £1,500,000, and of the tobacco and cigars £650,000.—*London Times*, July 17.

THE SWINGING OF THE PENDULUM: AND DEPRESSION IN TEA.

Just at present the adverse influences telling against the tea industry are about as complete as can be. Tropical agriculture is seldom otherwise than a risky trade, and when the planter has low prices, high exchange, heavy cooly advances, dear rice, re-bulking in London, and excessive loss of weight in some cases, to contend with, they all emphasise that riskiness in a most emphatic way. Only a few weeks back, the London financial papers were chorusing in a singularly unanimous manner what a good investment tea was, and singing the favourable outlook of the fragrant leaf; and the charm of the song at the time did much for Tea Companies and Tea Shares. It was the kind of piping to which the British capitalist likes to dance, and he footed the measure after an enthusiastic style. Big prices were paid for favourite estates in high districts, Companies were floated, shares were steadily on the rise, and the man who paused and wondered if everything had been considered, and if there was not just a trifle of inflation in the princely price per acre, did not thereby advance his reputation. He was considered a smart man who bought, and as for the long price paid—well, the places were worth it, and more. This has continued to be the feeling in London indeed up to the end of July; for a financial paper of the 27th ult., received by this mail, sums up the situation in the course of a long article on "Tea Companies":—"altogether, the shares of Indian and Ceylon Tea Companies combine the attractions of good security with what in these days may be called a handsome return in interest to an extent of which there are few examples indeed among the whole range of investments."

Here perhaps we reached our highest point a short time ago; for the outlook—save the fear of over-production—was clear, and the boom was booming. Now there is a change, and the swing pen of the dulum is very marked. If elation were the dominant tone before, and the song sung was both high-pitched and vehement, it is a doleful ditty we hear today, and that too in a minor key. The chirpiness has disappeared from Planting circles, and even in the local Commercial Capital there is an under-current of pessimism, with much shaking of heads. The Share List tells its own tale; for, whereas before there was a rush in, there is now a rush out; and it would not be hard to invest in almost any of the Companies therein named, at prices which a few months ago, would have found no sellers. Those with money to invest do not hesitate to tell their brokers, now-a-days, we believe, that they do not want tea shares—anything else but that.

Now, has the bottom fallen out of the Tea industry, or is this renewed swing of the pendulum in the opposite direction just what was to be looked for? As we have said above, there are at present divers causes telling against tea, but we have no hesitation in saying that most of them are temporary, and some although evil at present are really making for good in the long run. Low prices are not agreeable, but we have always found that they were the "open sesame" to many markets which before had been all but closed. Dear rice is only temporary and as yet the losses have been more than covered by a long way by former profits. Heavy cooly ad-

vances will work their own cure—though perhaps, some will suffer, for if there is to be "a squeeze" in tea, those who in the day of plenty gave little thought to the matter on the principle of "easy come, easy go," so long as we get coolies, will be forced to revise their policy. And then, as for the minor troubles in London, if they cannot be cured they will have to be endured. The Exchange question is we admit the puzzler,—the real "Asian mystery"—to prophesy about which, would be unwise even for the wisest. Still, although we claim to be no prophet nor the son of a prophet, we cannot help thinking, that a system of currency which has a fictitious value—the result of being bolstered up—has a very unstable equilibrium, and is more likely to collapse than aught else.

Meanwhile everything is telling against the tea producer, and the call is urgent for watchful care. With the great markets of America and Russia hardly tapped as yet, our staple industry has no cause to sit down and weep because it has no worlds to conquer. Our tea planters have had a fairly good innings of good times, and there are good times yet ahead; but it may be that for a little the road to be travelled may be rough, and the fare scanty. The Ceylon planter has been reared in the school of adversity: knows what it is to have his nose at the grindstone and will meet a check in a manly way. What we deprecate is the violent swings of the pendulum in public opinion and the tendency to be either soaring in the clouds or grovelling in the dust. Tropical agriculture is always liable to marked periods of action and re-action; and there is no need to be unduly depressed when re-action is dominant as it undoubtedly is at present.

VARIOUS PLANTING NOTES.

THE CONSOLIDATED TEA AND LANDS COMPANY, LIMITED—popularly known in Ceylon as Sir John Muir's Company—deals in very large figures and profits as may be seen by the Directors' Report given on page 234. The latter also affords very interesting information about dealings with other Companies—amalgamations and separations—purchase of estates and profitable re-sales. The parent Company occupies a strong position with £65,000 already in a reserve fund. The Hopewell Tea Company is one of the new Ceylon offshoots, representing the estates alongside of Balangoda.

THE "INDIAN FORESTER."—A monthly Magazine of Forestry, Agriculture, Shikar and Travel, edited by J. W. Oliver, Conservator of Forests and Director of the Forest School, Dehra Dûn, for July contains the following:—Original Articles and Translations—Shade, Cover and Shelter, Letter from F. G.; Correspondence; Reviews—Forest Administration in Burma, 1895-96; Timber and Produce Trade; Extracts From Official Gazettes; Report on Tour in France—Fire-prevention and the Forest of the Esterol; The Gurnaud System of treating and working forests or the so-called *Méthode du Contrôle*; The present system of Working Plans in France; Forest Management in a backward part of France "*Inspection*" of Bagnères de Luchon, Pyrenees; As above Savoie; Special investigation of Facts and Phenomena connected with the growth and maintenance of Forests. Establishment of Research Bureaux in Germany, Austria, Switzerland, and France.

AREKANUTS.—An estate proprietor writes:—

"Many of your readers would be glad if you would publish a market report for *arekanuts*."

Where can such be got we ask? Not we think in London market reports—the great mart for Ceylon arekanuts being in India; but we have never seen quotations in the Indian papers. The trade is, we suppose, entirely in native hands.

RADIOGRAPHY OF BUDS.—In a recent number of the *Gardeners' Chronicle*, Mr. G. J. Barch contributes an interesting article, accompanied with figures, upon the use of the x-rays for photographing flower and fruit buds. Mr. Barch and his assistants began by exposing plates of glass of different colours to the action of the rays. The violet glass showed itself much more opaque than that of other colours. It contained alumina and cobalt in addition to the ordinary elements. An experiment was afterwards made with a violet coloured hyacinth, and, as had been anticipated, the flower gave different results from those given by the glass. It was much more transparent. The sensitised plate, after development, showed the contour of the petals, the veins, and the internal that form of the ovary were well represented. Fortaking such radiographs Mr. Barch advises the use of tubes that give very little light, and that, for example, would scarcely give the contour of the hard parts of the hand. The aeriferous tissues are very transparent to the x-rays. The more water the tissues contain, the more opaque they are. Dry fruits and flower buds give excellent radiographs. The seeds are very distinctly seen, as are also the different parts of the flower.

JAMAICA.—The report on Jamaica for the past financial year which the Colonial Office has just published, shows that the colony is, upon the whole, prosperous. It is stated that the colonial public is now thoroughly roused to the importance of giving more attention to the cultivation of products. "There is a growing desire not only to cultivate, but to cultivate well, and to improve the quality as well as increase the quantity of these vernal crops." The local agricultural society encourages this tendency in every way. It must be long before the loss on sugar can be compensated for by other products, but the rate of increase in the latter is greater than the decrease no sugar, and for this the fruit production is mainly accountable. The decline in the cultivation of the sugar cane is gradual, but persistent; the increase in coffee, ginger, cocoa, and tobacco has been great; while that in bananas is very much greater. Thus twenty years ago 31.6 per cent. of the total exports was sugar; last year sugar was only 11 per cent., though the value of the exports had increased. The increase in fruit exports, and especially in oranges, is due to some extent to the destruction in the Florida groves by a blizzard in 1894. The value of the imports last year was 2,288,946*l.* against 2,191,745*l.* the previous year, while the exports amounted to 1,873,105*l.* The population of the island is estimated at 690,667. In conclusion, Sir Henry Blake observes that though the year was not one of special prosperity, it was not one of depression in the colony generally. Some industries have not been so fortunate as in previous years, but others have been prosperous. Trade has not largely increased, but it has not diminished, and the value of the imports is greater than in any previous year, showing that the purchasing power of the population has not diminished.—*British Trade Journal*, July 1.

THE DUMONT COFFEE COMPANY DIRECTORS—have acted wisely in their generation in putting £83,500 out of their first year's earnings to a reserve fund. This should surely restore confidence, and bring up their shares to par one would think. The Report given on page 235 has much interesting information.

COFFEE HUSK AS AN ARTICLE OF HUMAN CONSUMPTION.—Occasionally orders are received at Colombo from the Persian Gulf ports and Aden for coffee husk, the refuse thrown away after pulping the coffee. It appears that the natives there boil the husk, and use it as a kind of tea, or make a preparation and mix it with real coffee. The husk of *Libonia coffee* is preferred to that of either plantation or native cherry.—*Cor.*

TEA CULTIVATION IN NORTHERN INDIA AND CEYLON.—Many of our planters should be interested in the chatty and critical letter which "1874" (an Indian tea planter dating from that year) sends us elsewhere. Even if there be nothing much that local men can appropriate or utilise, still it is of interest, to learn how "manuring," "pruning" and "plucking" are dealt with in the different Indian districts named. One piece of advice is worth considering; it is to spend money in manuring rather than in extending tea gardens.

THE "AGRICULTURAL GAZETTE" of New South Wales, has the following contents for June 1897:—Remarks on the Object and Method of Soil Analysis; Chemical Notes; Reports on the Darling Pea; The Suppression and Prevention of Tuberculosis of Cattle, and its Relating to Human Consumption (Reprint); Pruning, Budding and Grafting; Pruning the Vine; The Fruit Fly; The City Abattoirs; A Tobacco-Growers' Association; Influence of Bees on Crops; The Treatment of Pelts; Orchard Notes; Vegetable Notes; General Notes; Replies to Correspondents; List of Agricultural Subjects Shows; Label for Specimens.

JAPANESE TEA BUREAUS.—In New York "Bra'streets" of July 3rd we have the following "business note":—

Among the passengers on the steamer "Gaelic," which arrived at San Francisco this week, "was a party of Japanese who have come to this country in the interest of the Japanese government and the Central Tea Association, of Japan, to establish bureaus for the regulation of the tea business here. There is now a bureau in existence in New York, and other bureaus will be established at Chicago and Montreal. The tea bureaus will serve about the same purpose in respect to tea as the viticultural bureaus in the eastern cities do in the regulation of the foreign wine trade.

THE QUEENSLAND AGRICULTURAL JOURNAL is a new publication, the July number being the first part. It is issued by direction of the Hon. A. J. Thynne, M.L.C., Secretary for Agriculture, and the contents of the first number are as follows:—

To our Readers, Some Things we Need, Organisation amongst Farmers, Agriculture—A Paying Crop for the West, Coffee-growing at Cairns,* Dairying—The Dairying Industry in Queensland, The Orchard—Fruit Culture in Queensland, Entomology—Destructive Insects Liable of Introduction to Queensland, Apiculture—Bee-keeping for Extracted Honey, Beekeepers' Association of Victoria, A Tropical Industry—India-rubber (Caoutchouc), Tea Farmers' Conference at the Gatton Agricultural College, Meat Export—Probable Meat Trade with Egypt, Botany—Contributions to the Flora of Queensland, General Notes—Rubber in Upper Burma, The Butter Industry of Canada, The British Import Trade in Eggs, Prickly Pears for Stock, Farming by the Wealthy Classes, The Maryborough Show, The Lockyer Show, Agricultural and Horticultural Shows, Show Fixtures, Farm and Garden Notes for July.

* We shall quote this short paper in an early issue.—ED. T.

"GREVILLEA ROBUSTA."

We call attention to the interesting letter, which a planting colonist, under the well-known signature "Senex," sends us respecting this tree. Our first acquaintance with it arose through a long series of vain attempts made by the late Mr. A. M. Ferguson under the encouragement of Dr. Thwaites of Peradeniya, to grow it at "Aloe Avenue," Kollupitiya. The plants flourished from September till May; but the saline breezes of the South-west monsoon invariably swept away their leaves, and the young trees dwindled down beyond recovery. We should like to know if *Grevillea Robusta* succeeds in the Kalutara or even in the Kelani Valley district? Upcountry, its success, as "Senex" points out, is unqualified. What he says of its uses as a timber-tree is very interesting, especially when coupled with the benefit conferred by its litter of fallen leaves, and through the tree tapping a deep subsoil. Mr. Cantlay of Mount Vernon, who, we suppose, has as fine a display of grevilleas as any planter in the country, ought certainly to get an analysis made by Mr. Cochran of the fallen leaves, to see what his soil exactly gains from them? "Senex" mentions that the tree or its branches are not very useful as fuel unless left to dry thoroughly. He also refers to its ready growth from seed; but would it not be well to get seed as a rule from another country—or at any rate, a different district—and to be sure that it is from fully matured trees?

Since writing the above we find Mr. Cochran has dealt fully with the leaves of *Grevillea Robusta* in his "Ceylon Manual of Analyses" (a book which ought to be in the hands of all thoughtful practical planters). We quote as follows:—

LEAVES OF THE GREVILLEA ROBUSTA.

As the tea plant is found to flourish best under a certain degree of shade, the tree called grevillea robusta, a native of Australia, has been largely planted on Ceylon tea estates. This tree serves the double purpose of breaking the force of the wind and of affording a suitable amount of shade for the tea plant. It is therefore interesting to ascertain how far this tree competes with the tea shrub for the plant food in the soil. With this object in view, two ten pound parcels of leaves were sent to the author for analysis; one parcel containing 10 lb. green leaves, the other 10 lb. of sun-dried old leaves.

It will be observed from the accompanying tables of agricultural analyses of grevillea leaves and the comparison of their composition with that of tea leaves, that, while the tea leaves are very rich in the more important constituents of plant food, viz., the nitrogen, potash, and phosphoric acid, the grevillea leaves are correspondingly poor in these constituents and are very rich in the less valuable lime. The tea and grevillea trees are therefore examples of different trees well suited to grow together on the same soil. It will further be observed that there is a very considerable difference between the grevillea green and old leaves. The latter show a smaller proportion of ash when calculated upon the dry matter of the leaf, and the ash is of inferior quality shewing more especially a remarkable decrease in the lime and potash and a correspondingly large increase in the siliceous matter. Supposing these old leaves to have lain on the ground for some time, part of this difference might not be in the constitution of the leaf; but might be accounted for by mineral matter being dissolved out and a small addition of persistently adhering soil, as an amount of adhering soil which would add a very trifling percentage to the weight of the leaf would add a considerable percentage to the weight of the ash of the leaf.

To the above remarks Mr. Cochran appends several tables of analyses of "Green leaves," "Old leaves, sun-dried," "Dry matter of old leaves," "Ash of green leaves," "Ash of old

leaves," and "Comparison of the important constituents of plant food in tea leaves and grevillea leaves." These ought to be consulted by all interested—and what tea planter is not?

CULTIVATION OF COCA ("ERYTHROXYLON" COCA) IN CEYLON.

A planter writes to ask us:—"What was the reason that the cultivation of *Coca Erythroxylon* (for cocaine) was not seriously taken up? I see by an old volume of the *T. A.* that an experimental lot of leaves sent home in 1885 was valued at 13s per lb. The plant is said to be almost naturalized about Peradeniya." Our correspondent will find a full history of our Ceylon experiments so far as they have gone in our "Planting Review" in "Handbook and Directory" pages 132-133. The one or two Ceylon planters who have gone in for coca have no doubt done very well; for the export of "coca leaves" has increased from 956 lb. in 1890 to 3,392 and 3,397 lb. in 1895 and 1896 respectively. The fear of overdoing the market (after the experience of cinchona) has no doubt kept planters generally in suitable districts—from Dambara to lower Pussellawa (?) or so—from going in for coca. We see that cultivation is extending in Peru; in fact we may as well quote what is said in the very latest Journal of the "Society of Arts" (July 30th) on the subject:—

THE PRODUCTION OF COCA IN PERU.

Before the discovery of cocaine and its anæsthetic properties, the consumption of coca was limited to the demands of those provinces in Peru in which the mining industry was carried on, the miners refusing to work unless they were supplied with coca. Twenty years ago, according to the *Economista* of Lima, the cultivation was only engaged in in districts which enjoyed the most favourable conditions of climate and labour. In the province of Ouzco, the systematic cultivation of coca was only carried on in the haciendas of Choquisongo and Sanjumas, and the production amply sufficed for the needs of local consumption and the mining industries of Salpo and Saypullo. For some time past the production of coca has greatly developed, and the province of Otuzco is at the present time the most important producing district in the north of Peru, its production exceeding even that of the provinces of Huamachuco and Cajabamba, not only as regards quantity but also quality. The number of plants is 2,700,000, and the majority of the plants in this province have not yet attained their full development. The coca from these districts is bought by two houses of Trujillo for the cocaine factories, of Lima, and as they enjoy a sort of monopoly, the prices vary at will. The proprietors of the haciendas of Huayobamba and Cayanchal are proposing to establish cocaine factories in close proximity to their plantations, which may have the effect of lowering the prices. With the exception of the hacienda of Chuqui lanqui situated on the river of that name, all the other coca plantations are found along the river Chicama. To obtain the best results, coca should be cultivated in places where the temperature rarely falls below 24° Centigrade (75° Fahr.) and frequently rises as high as 30° (86° Fahr.) As regards the altitude of the plantations, those of Callancas and Huayobamba are for the most part situated at an elevation of 3,000 to 4,000 feet above the level of the sea; a few are found as high as 5,000 feet, but the product in these cases is of an inferior quality. The haciendas of Chuquillanqui, and a few others of minor importance, are situated at an altitude of about 2,000 feet. The quality of the coca varies according to the soil. That obtained from dry ground is better than the product of a moist soil. It is for this reason that the Chuquillanqui coca, although frequently attaining a height of about 9 feet, is far from possessing the strength and aroma of that produced in

Calancas and Huayobamba. In the districts of Pampas and Calancas, there are about 80 small proprietors of coca plantations; at Compin the number exceeds 100, while at Chuquilanqui there are hardly 20, the cultivation of coca having only within the last few years been introduced in the latter district.

The latest quotation for Coca leaves in London is only 7d to 8d per lb.

Crop in Pikuls.

	1887.	1888.	1889.	1890.
Limburg ..	5,342	6,160	5,700	1,200
Ayer Dingin ..	3,913	4,657	3,145	3,671
Pangadjaram ..	1,964	7,970	5,550	3,000
Minjin ..	1,656	5,620	532	3,531
Monorarie ..	3,600	2,431	2,200	1,000
Karang Nongko..	2,400	5,000	4,000	2,000
Kati Manis ..	1,600	8,000	3,100	530

Let any practical planter work out these figures, and he will find a very healthy average at the end of them. The estimate for Limburg this year is 11,000 piculs; and there is every reason to expect that it will be realised. I have seen no poor soil. All is very rich, and of volcanic formation. The strongest complaint, that I heard was that there was too much ash in it. Considering that the analysis of the coffee bean shows over 30 per cent of potash, ash must be indeed abundant to be a sense of complaint! The hospitality of East Java is unbounded.

The Java system of cultivation is thus: they work the soil, not the bush. But little is done to the bushes after topping, except taking off the suckers; but the soil is kept constantly worked up and open. Very little manuring is done: in fact one planter said to me: "If my coffee needed manure I should abandon it at once." I went over one estate that had just given ten piculs per bouw. The coffee looked well and in good heart, and able to be the same next year. . . . Bawean is in regular communication with Java, and is only 8 or 10 hours' steam from Soerabaya. The climate of the hills is delightful: cool and bracing: and I think that, if Singaporeans realised that such a delightful little sanatorium as Prigin could be reached at such a cheap cost, more would avail themselves of it. I also heard much of a sanatorium at Tosari, 6,000 ft. elevation, but had no time to sample it myself. The country swarms with game. A few days ago a planter shot three tigers three nights running. You can scarcely go a hundred yards without finding pig-track; and there is other game in abundance. Let no aspiring young planter wishing to better himself, or out of a berth, say to himself, "Here is a paradise for a coffee planter, I will go and try for a billet." Unless a man knows the Dutch language and customs, and at least one dialect of Javanese, he will have to begin at the foot of the ladder on a salary of something like sixty rupees a month. Preference is also given to a man who has lived for a time either in Holland itself, or in Netherlands Indies. The etiquette in Dutch officialdom is somewhat complex: and a planter is frequently brought into contact with the officials, both in regard to his land and other taxes, his labour, and in many cases his water-supply. The dealings require much tact and "a deal o' salutin."—*Singapore Free Press.*

PLANTING IN JAVA : COFFEE.

Soerabaya is a "slummy" looking place—narrow streets—lots of mud and the roads rutty and bumpy enough to shake the liver out of one! To the stranger passing along the streets two things are especially noticeable; first, the marked absence of Chinese (happy Soerabaya!) and secondly, the happy, contented and intelligent look of the natives of the place—from a cursory glance I should say a much superior type to the Javanese we get in the Straits. In Soerabaya I was given some coffee figures which fairly took my breath away. I have more to collect and will give the whole lot together. At present I am *currente calamo* and *currente jalana*! The country appears to be very thickly populated, the markets that we passed being crowded with women buying and selling; in some cases I should say there were over 2,000 present in one market. It is a quaint sight to see them riding along sitting astride their ponies, with a big pannier hung on either side. To show how these Javanese drivers rattle their ponies down hill, I give the following: From Prorong to Pigin took us three hours. The return journey was done in one hour and twenty minutes! The steep portion of the ascent was done in one hour and three quarters, with much whip-thong and bad language. The same on our return was done smiling in twenty-three minutes. Before I forget it the etiquette of calling in Soerabaya seems curious. The correct hour is from 7 to 8 p.m. and you have to give notice if you intend to visit for fear of finding the ladies in sarong and kabaya. This last was told me in a whisper, so please print accordingly.

The coffee in East Java is wonderful. As in other countries, there are failures; but the successes are marvellous beyond description. *All the coffee is grown under dadap shade*; and, where the soil has any inclination to stiffness, it is constantly worked up with changkol. The young coffee is very forward; but perhaps figures of actual results will be more interesting than the most glowing descriptions of appearance. One estate that I went over gives the following returns:—Total area 450 bouws. Age of coffee 12 years old to 2½ years old. All expenses, including the cost of the young coffee not yet in bearing, are paid: and the coffee has further given a clear profit of two hundred and fifty thousand rupees over and above the capital invested. Ye gods and little fishes! Let us pray that the Malay Peninsula may erupt heavily. The old saying is "It's money that makes the mare to go." I am sure that it's volcanic action that makes the coffee to grow. I am more or less sensitive about being called an Ananias; so I give the following figure taken from a Dutch Directory. The results are extraordinary, but I simply tell the tale as it was told to me. The appended table will, I am sure, be of interest to many a planter:—

TABLE OF RESULTS FROM SEVEN COFFEE ESTATES IN EAST JAVA.

Estates.	Elevation. ft.	Bouws.	Crop in Pikuls.		
			1884.	1885.	1886.
Limburg ..	1,200	600	1,705	500	2,041

Kati Manis ..	2,000	550	6,000	3,350	6,000

OOTACAMUND BOTANIC GARDENS AND PARK : ECONOMIC PRODUCTS.

As regards the Report itself, there is not much of local interest unless it be the figures showing how low is the rainfall of Ootacamund—the average of 47 inches being exactly half that of Nuwara Eliya:—

The average annual rainfall of Ootacamund is 47 inches. The rainfall for the year was 76·07 inches, or 28·15 inches more than was registered during 1894-95 and 29·07 inches more than the average. The heaviest rainfall was in June when 26·91 inches of rain fell on 24 days. The monsoon burst with unusual violence, but did no material damage beyond blowing down a large unsightly old tree of *Cupressus macrocarpa* Hart. and blowing a few branches off trees generally throughout the gardens. The fact that little damage was done is chiefly due to the sheltered position the gardens occupy in the Ootacamund valley. Of a few notes on Plants of Economic Interest, we quote the following:—

Ipecacuanha (*Cephaelis Ipecacuanha*, Rich).—Very little interest seems to be taken in the cultivation of this plant, the powdered annulated roots of which form the *Ipecacuanha* of commerce.

Dandelion (Taraxacum officinale, Wigg.).—No indents for dandelion root were received during the year from any of the Medical Stores departments, and so the crop here has not yet been lifted. It can well be left growing for another year or longer without deteriorating in value.

Chiretta.—Messrs. Babannaya & Co., Mangalore, wrote for information regarding the "chiretta" plant in this Presidency. They were informed that the true "chiretta" plant (*Swertia Chinata, Buch.—Ham.*) is a native of the mountainous regions of Northern India and that it is not found in Southern India, but that a substitute for it (*Exacum bicolor, Roxb.*) appeared to be used in Ootacamund. The nature of their inquiry led the Curator to suspect that it was just possible that a substitute for the true species might be used here. He accordingly obtained two samples of the dried "chiretta" plant—one from the Ootacamund Bazar and the other from the Ootacamund Hospital. Both proved upon examination to be identical, namely, *Exacum bicolor, Roxb.*—a native of the Deccan Peninsula. Although belonging to different genera both species belong to the same natural order (Gentianaceæ), and, therefore, doubtless possess bitter tonic properties in common.

The Douglas Fir (Pseudotsuga Douglasii, Carr.).—The District Forest-officer, Nilgiris, forwarded a packet of seeds of this species with the request that they might be sown and, should they germinate, that he would like to have half the resultant seedlings, the other half to be kept for the gardens. These seeds were sown in two boxes on the 26th October 1896 and it has been interesting to watch the process of germination of the seeds of this conifer. A certain proportion of the seeds germinated in three weeks, and the remainder have been germinating in succession, week after week, till the end of March: in other words, the process of germination has been going on in succession over a period of five months. The seedlings are only about 1 to 1½ inch in height at present, but they are in a perfectly healthy and promising condition. This species grows to a height of 150 to 200 feet, and forms immense forests in British Columbia and Oregon. Many of the precipitous slopes on the higher parts of the Nilgiris might be profitably planted with species belonging to the natural order Coniferae.

COFFEE-GROWING AT CAIRNS, N. QUEENSLAND.

From the *Cairns Post* we reprint the following extracts from a private letter written by a well-known resident to a friend in England in reply to queries re coffee and sugar growing in the district:—"On the low-lying lands between the sea-coast and the foot of the Cairns ranges, the climate from about September to March is more or less damp and steamy, of course, perfectly suitable for tropical agriculture, such as sugar, which is fast becoming a very large industry. There is plenty of scope for sugar-plauters; the soil is rich and well watered; rainfall very good; remaining months of the year are cool and pleasant. Ascending the range by railway, a sort of hilly tableland occurs, which extends inland, but which, for some miles around the vicinity of Kuranda and extending in each direction about parallel with the coast, is covered with dense tropical scrub. The soil is exceedingly rich in many places, and this portion of the tableland is from 1,100 to 1,600 feet above sea-level, and averages about six miles from the coast. This prevents frost in the cool months; and the sea breezes in the warm months, being above the influence of evaporation, are very cool and pleasant. The thermometer goes down to about 36 degrees in winter, and averages about 83 degrees in summer. Further inland again, at Atherton, about fifty miles from Cairns, lies an immense belt of agricultural country covered with very heavy scrub full of valuable timbers. The land about Atherton is about 2,500 feet above sea-level.

"Frosts occur in the cold months, and the climate with the exception of about three months out of the year, is probably as near perfection as it is possible to be. The soil about Atherton is generally considered to be amongst the richest in Australia. The rainfall is also good. The average rainfall at Cairns and on the adjoining ranges is about 80 to 100 inches per annum, well distributed. It is generally considered that along the top of the range or tableland, where the soil is good and no frost occurs, is the best place for growing coffee. There is no doubt, as has been proved, that at any rate up to about six years the coffee-trees grow exceptionally well and bear heavily when properly planted, but a lot yet remains to be proved before the industry can be called a perfect success, although enough has been proved to warrant anyone going in for it with an exceptionally good chance of success. With regard to labour, there is a moderate supply of Kanaka labour available, which is good labour. Wages are from £16 to £18 per annum and find them in food. (Children (who pick well) are available to cope with it for some years to come. From the crops already picked, it is generally expected that, with 430 trees to the acre, about half a ton of dried beans to the acre may be relied on when the tree is five years old; the trees generally commence to bear when three years old, and the dried beans are worth about £90 per ton. The price of land is £4 per acre, varying in different localities. Anyone going in for coffee, by looking well around, might possibly pick up good bargains. The approximate cost of purchasing and preparing uncleared scrub land per acre for coffee would be about as follows:—

Purchase of land, say ..	£4
Clearing and burning off scrub ..	4
Grubbing up stumps ..	8
Digging holes for plants ..	5
Etc. ..	1
	<hr/>
	£22

"To put, therefore, say 20 acres under coffee would cost approximately as follows:—

Purchase of land, preparing same and planting coffee, 20 acres at £22 per acre ..	440 0 0
Fencing, say ..	60 0 0
Dwelling-house, say ..	150 0 0
Farming implements and horses about ..	100 0 0
Cultivating plantation for say, three years until trees bear, allow ..	150 0 0
Contingencies, allow ..	50 0 0
	<hr/>
	£950 0 0

"Add to this the cost of living, say, for three years. When trees are three years old you could expect a small return, which would increase to full returns when the trees are five years old. Half a ton of dried beans would be worth £45, and the profit per acre could be estimated at £20, according to present prices, which are considered lasting. That is: By an expenditure of, say, £950, and cost of living for three years, you should expect a return from 20 acres of coffee of about £400 per annum in five years from sowing the seed; allow about profit of £200 the fourth year. I may mention also that there are many other things that can be grown with more or less profit besides coffee and sugar, such as oranges, lemons, limes, citrons, mangoes, coconuts, bananas, maize, rice, ginger, pineapples, and many other things. Going further inland, there are immense tracts of rich mineral and pastoral country, producing gold, copper, tin, and silver, and carrying thousands of cattle. For anyone with a moderate amount of capital, and a fair stock of health and energy, especially young fellows with the best part of their lives before them, I think there are few better places than this for them to make a start and expect a good return for their outlay.

"It must be noted that the above approximate estimate of outlay and profit refers to men who are not used to manual labour themselves, and would

have to employ all the labour required. Of course, any man used to manual labour, or if married, or if he has children, could do, say with the help of a few kanakas, all the necessary work, and could put smaller areas under coffee at a much less outlay, and expect a larger profit per acre. This would apply in particular to married men with families."—*Queensland Agricultural Journal for July.*

COST OF LIVING ON S. INDIA PLANTATIONS.

Sir,—Absurd stress has been laid on my omission of the dhoby's charges. He costs me exactly four rupees for three washes a month, as from long experience I have found that to insist on the weekly wash is to attempt the impossible. Instead of that, I merely have to lay in a larger stock of clothes. Not out of the 50 rupees a month, mind you, for I distinctly stated that clothes weren't to be got out of this sum at all. My bill of fare runs somewhat as follows, as it may interest your indignant correspondent to know the composition of the "last straw":—

Chota Hazri.—Porridge, a chop or steak, bread and butter and jam (home-made), and tea or coffee.

Breakfast.—Rissoles, or chop, or joint. Curry and rice. Bread and butter and cheese.

Tiffin or Tea.—Bread and butter, jam and cake, also cold meat if joint is on out.

Dinner.—Soup, joint or made-dish, curry and rice and bread and butter and cheese or plain pudding.

As for drinks, an occasional peg.

My bazaar bill now costs me for meat, rice, fruit groceries) R3 8, or say R16 per month. Soap, butter, jam, bread, tea or coffee, milk, &c., R10 per month. Liquor and smokes, R15. Dhoby, R4. Boy, R15. Total R50. Add, R15, for estate clothes and boots, you arrive at my R75 per mensem, which I estimated would keep a young planter very comfortably. Personally, I think that R100 is the lowest one should offer a European of over 18 months' experience in planting. But as a beginning, R75 should not be sneezed at, especially if yearly additions are promised—if work is satisfactory—of R25 per mensem.

By the way, a "Planter's Wife" gave some excellent directions some time back how a young planter should be able to keep a respectable and comfortable house on R100 a month or so. While R100 is better than R75, and R75 than R50, no man need starve or even stint himself if he has R50 a month to his name."

EX-CREEPER.

—*Planting Opinion*, Aug. 7.

COFFEE PLANTING IN SOUTHERN INDIA: MEETING OF THE UNITED PLANTERS' ASSOCIATION.

At a recent meeting of the United Planters' Association of South India an able, interesting, and important discussion took place on the subject of "scientific investigation" into diseases affecting coffee, divided into two parts, one being leaf disease and the other scale pests. The discussion on leaf disease was opened by Mr. J. A. Harris who said (after reading Ceylon literature on the subject) he had reluctantly come to the conclusion that further investigation by an expert as to *Hemileia Vastatrix* would not be likely to add much to what was already known. He was inclined to the belief that, since the disease was not constitutional, but external, attacking only the leaves, a cure of a permanent nature was not likely to be discovered; and that they should turn their attention, as intimated both by Mr. Marshall Ward and Dr. Trimen to maintaining their trees in such strong vitality as would enable them to resist the attacks of this pest. As to how this might best be done he referred to careful cultivation and

judicious manuring. With regard to the former he emphasized the soundness of Mr. Marshall Ward's opinion that they should aim at making the plants grow leaves during the time that the disease was least likely to be propagated and avoid the growth of young and succulent wood when the spores are most blown about,—with the object of having the trees at the time of visitations covered with matured leaves both able to resist the disease and of having them as far as possible free from young ones on which the spores germinate with great rapidity. It was rather curious to notice that in Ceylon the worst attacks of *Hemileia Vastatrix* were usually in the S.-W. Monsoon, during the months of June, July and August, whereas in Mysore, and he believed in other parts, the worst visitations came in September, October and November, and sometimes extended over January and February. Moisture, heat and air being necessary for the spores, he presumed that the damp chill of the S.-W. Monsoon checked it. With reference to digging he considered it was a moot point whether deep cultivation checked the disease, the tendency nowadays being to avoid stirring up the soil more than necessary. As to manure he considered September as far as Mysore was concerned a better month than August for applying manure. Applications however, must be greatly influenced by the supply of labour. As to what manures they should apply he said that in this matter the planting industry of Southern India required the services of an Agricultural Chemist, his arguments in favour of getting a thoroughly competent man from home being that the mechanical conditions of a sample of soil sent home must undergo change in transit, and that a man on the spot would be in a position to observe the organic condition of the soil which would enable him to give a more accurate and valuable report. He concluded by moving "that this Association is of opinion that the time has arrived when the services of an Agricultural Chemist are essential to the future welfare of the Planting Industry in Southern India." Mr. E. G. Windle seconded Mr. Harris's Resolution. A discussion ensued which was taken part in by Messrs. O. Scott Skirving, Leeming, Parsons, Hay, Hodgson and Hockin and on the meeting going into Committee the following resolution was adopted:—"That a Sub-Committee be formed to consider the various proposals put forward, and to advise as to the result in general meeting and that for this purpose Messrs. Harris, Windle, Acworth, Parsons, Hocken, and Leeming do form the Sub-Committee."

The discussion on scale pests was opened by the Hon. Mr. Hodgson who said that a Government Order had been issued which was very satisfactory. It said that Government was desirous of seeing an entomologist appointed at an early date, and had already communicated with the Government of India as to the best means of obtaining one. That showed that the Madras Government had taken a great interest in this subject and he could speak himself of this being the case. This scale pest was increasing rapidly, and in Districts in which it existed it was almost as serious a matter as leaf disease was in the Districts where that existed, and everything should be done to eradicate it. Mr. H. O. Newport supported Mr. Hodgson's remarks in a speech in which he referred to various methods of dealing with the bug. He obtained a spray solution from the Chiswick Soap Company called "Spinno," and sprayed this evil

smelling liquid on to the trees with matter in proportion of 100 parts to 1 as directed by the Soap Company. This had no effect whatever; in fact the bug seemed to fatten on it! Stronger solutions had better results but even then he never succeeded in killing out at the scale on any one branch or leaf. He also tried a mixture of kerosene and soft soap in water in various proportions—also an infusion of quassia bark. Also mixtures containing in various proportions, turpentine, tobacco decoction, sulphur, lime, etc. Some of these seemed to have temporary slight effects but none did any lasting good. The conclusion he had arrived at was that lady birds would be not only the easiest and most effective way of getting rid of scales, but the only possible way of doing so. He suggested that the Government of Madras should communicate with Mr. E. E. Green (Ceylon) on the subject and ask him if he would be willing to come over and undertake the working out of this matter on the lines of the experiments so successfully made in Hawaii. The following resolution proposed by Mr. Acworth was adopted:—"That a small Sub-Committee be appointed to decide upon an amount to be taken from the Reserve Fund to be added to any sum raised by the Lower Pulneys and other Associations for the purpose of immediately introducing the Lady Birds." Other resolutions adopted were:—"That the Secretary be instructed to forward copies of the correspondence on this subject to the Secretary of the Indian Tea Association, Calcutta, with a view to obtaining the support of that Association in the matter of the employment of an entomologist and the subsequent introduction of the national enemies of the various insect pests inimical to tea and coffee." "That this Association would wish to record its thanks to H. E. the Governor and the Government of Fort St. George for the active interest he has taken in the subject of the introduction of lady birds and other natural enemies of the insect pests to which tea and coffee are subject, and for the promise of practical help as conveyed in the G. O., No. 634, of the 27th July 1897." "That if the necessary support can be obtained from planters and the firms engaged in the manure trade, the U. P. A. S. I. engage to subsidise a suitable Agricultural Chemist for the purpose of analysing manures, soils, etc., by a standard method and advising on all points of planting chemistry." "That this matter be enquired into by the Sub-Committee appointed to consider the question of leaf disease, and if it is resolved that an expert shall be employed, that the Sub-Committee do also suggest what sum should be allotted from the Reserve Fund in aid of that purpose."

It is clear from the whole of the discussion that with both leaf disease and green bug to contend with, the end of coffee in India (as in Ceylon) is approaching unless lady birds can be introduced to stop the latter.

INDIA-RUBBER FORESTS IN MANY LANDS.

MAJOR KERBEY'S SOUTH AMERICAN TOUR

Letters have reached the India-Rubber World lately from Major Joseph Orton Kerbey, dated at Mollendo, Peru, whence he purposed starting overland through the rubber districts of Peru and Bolivia, expecting to reach Para via the Amazon during September. In his report Consul Kerbey declared his

belief in the practicability of introducing the Para rubber-tree into southern Florida, and his present mission to South America—the second since his official residence in Para—is based primarily upon plans in that direction, though he is also looking for ethnological and other specimens for museums. Major Kerbey left New York on the "Lucania" on January 16. From England he sailed for South America touching at Peruambuco on March 4 and later at Buenos Aires, whence he travelled by rail and on mules to the Pacific coast. On May 20 he reached Mollendo, the starting-point of a railway to Lake Titicaca, beyond which several land and water routes may be followed to as many important rubber districts. At Buenos Aires the government expressed considerable interest in Major Kerbey's journey and offered to send him to the *gran chaco*, adjoining the Brazilian state of Matto Grosso, to report on the practicability of cultivating rubber there. He declined this, but when he left there was talk of organizing a rubber-exploitation company at Buenos Aires. "We propose," Major Kerbey writes, "to start a nursery in south Florida, capitalized at \$100,000, to propagate plants of India-rubber, cocoa, vanilla, and orchids. We want to sell plants of rubber of different sorts to companies to be formed for cultivating them in Florida, the isthmus of Tehuantepec, Central America, etc. When I get back, with 100,000 genuine rubber nuts in my possession, I know the land is ready and the money in hand to germinate them in our nursery. If you print anything about it, say that this nursery is established at Orlando, Fla., and Professor O. F. Winkelman will give information. Some rubber seed have already been sent there."

PERUVIAN SOLDIERS GATHERING RUBBER.

In an article on the revolution last summer in the rubber district of eastern Peru, Richard Payer, writing from Iquitos,* makes a note of interest on the way in which the force of rubber-gatherers is recruited incidentally in that sparsely-settled country. Writing of the soldiers brought across the Andes from the coast districts to suppress the rebellion, Herr Payer says: How long the troops will feel at home in this tropical climate is difficult to say; at all events it would be unprofitable for the Government to transport them back over the mountains. As in the past, doubtless most of these defenders of their country who have undertaken the expedition into the un-hospitable forests of eastern Peru with adventurous expectations will remain to become peaceful rubber-gatherers. They will discard their swords for rubber-paddles, and over the smoke of their camp-fires turn the milk of the rubber-tree into a merchantable product. At the present advanced prices, it requires little effort to make a rubber ball, which, at the weight of 120 kilograms, is worth 1000 francs in gold. Such a ball, while the present abundant supply of milk lasts, can be gathered by a family consisting of two or three persons in eight days; the children are especially adapted for this work on account of their agility. Thus material progress, healing all wounds, converts many an evil into good, and the rubber-men of eastern Peru will soon have regained the losses sustained through the war, the increased population enlarging the production. Rubber is, and will remain, the best paymaster, and North America, for export and import alike, affords the best market. There is a condition of solvency of the business world here which denotes that commerce is blooming anew from the ruins of the revolution.

ANOTHER OUTLET FOR BOLIVIAN RUBBER.

An enterprise under way in South America, backed by New York capital, but about which little has yet appeared in print, is thus referred to in the *Panama Star and Herald*:—According to *El Economista* (Lima), the firm of Ballivian & Co. has completed two-thirds of the road around the rapids of the river Madeira between Brazil and Bolivia, and will open the route to traffic January 1, 1897. This is only a cart-road with a total length of 112 miles, but it is of great importance. The disastrous attempt of Colonel George

* In *Petermann's Mitteilungen*, XLIII (1897), 43-45.

Earl Church to build a railroad around these rapids from San Antonio, on the Madeira, to navigable water on the river Mamore in Bolivia, is well known. But the natural trade route into the rich regions of eastern Peru lies that way, and the desire to open it up is irrepresible. It is stated that Ballvian & Co. are backed by the Para house of R. F. Sears & Co., whose intention is to stimulate trade by this cart-road with a view to the construction later on of a railroad, with further extensions towards Cuyaba in the Brazilian state of Matto Grosso, thus drawing the trade of that region also, which now goes down the river Paraguay to La Plata ports, in the other directions via the Amazon and Praa to United States and European markets.

The river Madeira forms the only water outlet for THE REPUBLIC OF BOLIVIA,

with a larger area than any European state save Russia. Into the Madeira flow streams which form a great system of waterways, draining every corner of Bolivia, and all those rivers are lined with rubber trees. It was not until 1880 that the first shipment of rubber from Bolivia was made, but in a single year recenly 1,600,000 pounds of the finest rubber in the world, commanding the highest prices, have been floated down her rivers, into the Amazon, and out upon the Atlantic at Pará. This rate of progress will not seem insignificant when it is remembered that, owing to dangerous cataracts in the Maderia, scattered over long distance, a cargo of Bolivian rubber is sometimes three months on the way to the seaboard, at a cost of transportation of 25 cents per pound, to say nothing of what is lost through the capsizing of boats. In the belief that transportation in cattle carts will be cheaper and occupy less time, the road referred to has been opened. Cattle are as plentiful in Bolivia as rubber is, and, at present, cost practically nothing. With the development of trade which is expected to follow the opening of this new outlet for rubber and cattle the *cessionnaires* believe that capital will be forthcoming for a railway to replace the cattle trail. Today the predominant idea in Bolivian national life is the development of the state by making her resources available, and the resource first considered invariably is rubber. The concession referred to above is held by a company headed by Sr. Adolfo Ballvian, who for some time past has controlled important contracts with the Government. The interest of Mr. Sears in the matter had its beginning a year ago or more, and he is confident of an important development in due time. The preceding has been in type for some time past, and is now printed without revision for the reason that the cart-road has not yet been completed. This has been retarded, the Indian Rubber World is informed by Mr. Sears, who is now in New York, by the fact that the laborers have been so largely utilized in gathering rubber. It is expected, however, that the road will be opened before the coming transportation season is ended. Since whatever rubber is produced hereafter on the Beni or in Bolivia will naturally come over this road, a very material saving in transportation charges is anticipated.

The newspaper *El Economista* reports that the EXPORT OF INDIA-RUBBER via Villa Bella in 1895 reached 1,712,544 pounds, of which 1,545,412 pounds were "fine" and 167,132 pounds "sernamby," or coarse. The greater amount of this was the product of Brazil and the remainder of the Brazilian country drained by the Mamore. A British consul in Bolivia, Mr. Alfred St. John, estimates the annual production of Bolivian rubber at 850 tons, provided that none is smuggled out of the country. There is an export duty of one boliviano per arroba of 25 pounds, with a duty one-half as large on coarse rubber.—*India Rubber World*, July 10.

THE MOVEMENTS OF COFFEE.

The trade coffee year, which closed June 30, has passed into history with a record of large supplies; increasing stocks; unusual advance in deliveries; heavy decline in prices, amounting to 5½ cents per pound for No. 7 Rio.

From 1887 to 1896 was a period of high prices, during which production was stimulated in Mexico, and Central and South America. The usual yearly gain in consumption was checked. The deliveries as will be noted from the table below varied slightly from the yearly average of 643,270 tons (or 10,935,595 bags) for the five years 1891-92 to an including 1895-96. During the year 1896-97 they reached the highest point on record in the United States, or 5,088,594 bags; in Europe, 7,155,610; total for two countries 12,244,204 bags, making the banner year for the coffee industry.

Present indications point to an era of low-cost coffee and steadily increasing consumption, due primarily to low prices, and, secondly, to the development of the coffee roasting indury and to the stimulus to demand, resulting from vigorous efforts to push the sale of package coffee. The bulk of the coffee consumed is of medium and low grade, used extensively in sections which formerly bought the raw bean, which was roasted as desired by the consumers, who have discovered that package coffee is of uniform quality, while its use saves time and trouble.

The total deliveries of all kinds of coffee in 1896-97 compare with deliveries of five preceding years as follows:—

EUROPE AND UNITED STATES.		
Year.		Bags.
1896-97	12,244,204
1895-98	11,142,813
1894-95	11,212,851
1893-94	10,571,533
1892-93	10,946,228
1891-92	10,804,551
Total, six years ..		66,922,180
Yearly average (656,099 tons)		11,153,697

The deliveries in Europe in 1896-97 show a gain over 18:5-96 of 351,925 bags, or 5.17 percent. They compare with the five preceding years as follows:—

DELIVERIES IN EUROPE.		
Year.		Bags.
1896-97	7,155,610
1895-96	6,803,685
1894-95	6,820,905
1893-94	6,272,688
1892-93	6,547,679
1891-92	6,392,719
Total, six years ..		39,993,286
Yearly average (392,091 tons)		6,665,548

The United States consume more coffee than any other country in the world in the aggregate, but its use per capita is far below Belgium, Holland and Denmark. The deliveries in 1896-97 compare with five previous years as follows:—

DELIVERIES IN UNITED STATES.		
Year.		Bags.
1896-97	5,088,594
1895-96	4,339,128
1894-95	4,395,946
1893-94	4,298,840
1892-93	4,393,549
1891-92	4,411,832
Total, six years ..		26,932,889
Yearly average (264,048 tons)		4,488,814

THE SUPPLY.

Brazil is the colossal producer and the dominant factor in the markets of the world. In 1896-97 that republic furnished 70.89 per cent. of the total

arrivals of coffee in Europe and the United States, and 77.09 per cent. of the arrivals in the United States:—

The exports from Rio and Santos for the year ending June 30th, 1897, compare with the preceding seven years as follows:—

	To. U. States.	To Europe	Total Exports.
	Bags.	Bags.	Bags.
1896-97 { Rio, Vic., etc.	2,616,000	1,081,000	8,634,000
{ Santos	1,565,000	3,369,000	
1895-96 { Rio and Vic.	1,746,000	899,000	5,762,000
{ Santos	1,050,000	2,067,000	
1894-95 { Rio	1,816,000	687,000	6,401,000
{ Santos	1,347,000	2,551,000	
1893-94 { Rio	1,641,000	606,000	4,016,000
{ Santos	797,000	972,000	
1892-93 { Rio	1,972,000	953,000	6,295,000
{ Santos	1,102,000	2,268,000	
1891-92 { Rio	2,556,000	1,148,000	7,267,000
{ Santos	997,000	2,556,000	
1890-91 { Rio	1,556,000	750,000	5,537,000
{ Santos	798,000	2,253,000	
1889-90 { Rio	1,767,000	721,000	4,570,000
{ Santos	512,000	1,567,000	

It is a matter of interest to note the irregularity of the Brazilian crop. In 1890-91 there was an export of 7,267,000 bags; two years later, of 4,016,000 bags. If two heavy crop years, such as 1896-97 and 1897-98 (as now estimated), are succeeded by a light crop, as is not improbable, we may anticipate a sudden marked rise in cost. Nature is not a confirmed prodigal.

STOCKS.

The total stock of all kinds in the United States July 1, 1896, was 375,113 bags; July 1, 1897, 676,856 bags—an increase of 301,743 bags. Stocks of coffee in Europe July 1, 1896, 1,569,080 bags; July 1, 1897, 2,332,024 bags, a gain of 762,944 bags.

The total visible supply of the world, as reported by the New York Coffee Exchange July 1, 1897 was 3,975,880 bags, against 2,583,193 bags July 1, 1896, an increase of 1,387,687 bags.

The gain in supply will fully offset the estimated reduction in the Brazil crop of 1897-98, while the probable increase in other countries will result in a world's supply this year more than equal to requirements of 13,500,000 bags as follows:—

Visible supply, July 1, 1897	..	3,975,880
Brazil crop, 1897-98	..	7,000,000
Other crops	..	4,800,000

Total estimated supply 1897-98 .. 15,775,880

—*American Grocer*, July 14.

THE MADRAS GOVERNMENT CINCHONA PLANTATIONS.

The late Mr. M. A. Lawson, who for twelve years had controlled the Cinchona Plantations of the Madras Government on the Nilgiris, died early in 1896, and Mr. W. M. Standen, a planter of some sixteen years' experience and of established reputation was appointed to succeed him. It is an open secret that this appointment, though passed in Calcutta, did not find favour at the India Office. The Secretary of State, preferring doubtless that he should select an officer as he had selected the late Mr. Lawson, withheld his sanction and in the euphemistic phrase of the Madras Government, the matter "was under correspondence" during the year. Finally the authorities in London gave way and agreed to the Madras Government's nominee holding office, at least on a five years' trial. It must, therefore, be a considerable source of satisfaction to the Government to find, as appears from the Annual Report on the Cinchona Plantations during 1896-97, that the results of that year's working under Mr Standen's control have been so satisfactory as fully to justify its selection. During the twelve years of the late Mr. Lawson's control, the revenue of the Department only twice exceeded the expenditure, and then only by a sum of about R1,500. In the

year 1896-97, on the other hand, a surplus of R69,000 has been shown, the expenditure being reduced while the receipts were R42,000 more than in the previous year. The Government, never very lavish of praise, remarks that "the administration of the Department must, in these circumstances, be considered to have been eminently successful."

The remarkable improvement in the results of the Government's Cinchona enterprise during 1896-97 appears to have been due to a very simple cause. The quantity of bark used in that year was practically the same as was used in the previous year, 238,000 lb. as compared with 234,000 lb. But the quantity of drugs extracted has risen from 5,900 lbs. to 11,241 lbs., or by very nearly cent. per cent. The percentage of the yield of quinine to bark was 3.3 as against 1.5 in the previous year, or more than double; and the effect has been to turn the operations, which for years had been conducted at a loss, into a very paying concern. The increased yield from the same quantity of bark was, of course, due to the more thorough extraction of the alkaloids* and it certainly does not say much for the efficiency of the previous régime that it was left for Mr. Standen to discover this. The other results of the working of the Cinchona Department in 1894-97 appear to have been equally good. The quantity of quinine manufactured and the quantity sold during the year were the highest on record. The sales of the drug are now mainly conducted through the Post Office. The quinine is made up in five-grain powders and there are 1,550 Post Offices in the Presidency where these are kept. The idea is to bring the alkaloid to the doors of the people and to supply it at cost price and in small quantities. Apparently this plan is likely to succeed, for though it was only started in July, 1895, 4,180 packets were sold in 1896-97 as compared with 664 packets in the preceding year. As the diffusion of the use of quinine among the native population can hardly be other than beneficial, this aspect of Government's enterprise in cinchona can be entirely applauded. If the whole output of the Government plantations is thus utilized, most of the objections to the growing of cinchona by the State will be met, for the system of Post Office distribution reaches a public which, otherwise, would never use the drug at all. The most difficult thing to ascertain from an Annual Report such as that under notice is the actual state of the plantations; and this is doubtless the real crux of the management. It is stated, however, that there were 31,500 more trees at the end of the year than at the beginning and that a new system of transplanting seedlings was introduced which is expected largely to reduce casualties. As the good financial results were produced without any increase in the amount of bark consumed, there is no reason to suppose that the plantations were overcut, and the general impression left by the Report is a highly favourable one.—*H. Mail*, Aug. 20.

NEW AREAS OF CULTIVATION IN PUTTALAM DISTRICT.

There was no marked progress in this respect. Capitalists are on the lookout for land for cocco-nut cultivation in the south of the district, but up to the end of the year no land had been set free for sale. There are very extensive tracts of suitable land, but the equally extensive projects of the Forest Department in the matter of forest reserves tied up all this land. The limitation of these proposals within reasonable bounds was awaiting decision, which was expected early in 1897, when it may be hoped that some suitable land may become available for sale. About 35 more acres were opened under Maha Uswewa, the largest tank in the district.—*Mr. G. A. Baumgartner's Report for 1896*.

* And the greater age of the bark.—*Ed. T.A.*

CEYLON EXPORT TRADE IN COCONUT OIL.

Our Export of Coconut Oil to the United Kingdom and the Continent of Europe has been reduced, it is believed, owing to its great abundance in these markets, and consequent low prices; and, relatively to Coconut Oil, the cheap cost of Tallow during the last few years, and also of Cotton-seed Oil, both of which can be used instead of Coconut Oil for many purposes, although a certain quantity of Coconut Oil must be employed with them to obtain the best results in soap and certain other manufactures.

With regard to America, it is believed that, in addition to the above causes, the Silver troubles of the United States have had much to do with the falling-off in our Export of Coconut Oil to that Continent.

Up to the middle of 1894 there had been a gradual increase of our Export of Coconut Oil to India; but the Import Duty of 5% *ad valorem*, which was placed on all Imports into India about March 1894, had the effect of practically putting an end to the trade in our Oil, as it handicapped us to the extent of R17 or R18 per ton as against Cochin Oil which, of course, is not subject to the Import Duty.

About two years ago drought in Cochin caused Coconut Oil there to rise in price, and to such an extent that it again began to be possible to ship Ceylon Oil to India with advantage, and our Oil being much cheaper to lay down than Cochin Oil, and the facilities of shipment from here being very great, this trade has continued until now to expand to quite a remarkable extent, as the following figures will show, viz:—

EXPORT OF COCONUT OIL FROM CEYLON TO INDIA.

	Tons.		Tons.
1890 ..	4,946	1894 ..	1,115
1891 ..	5,346	1895 ..	737
1892 ..	5,810	1896 ..	4,339
1893 ..	5,734		

And for the 7½ months of 1897 to 17th August, the Export has been 4,087 tons against 1,997 tons for the same 7½ months last year.

In India the Oil is used for burning and other domestic purposes only, and not in manufactures, and it has not to compete with Tallow and Cotton-seed Oil, &c., as in Europe and America. Cochin Oil continues to be much dearer than Ceylon Oil, and as the consumption in India seems to be capable of great expansion, it appears as if the Export for this year, 1897, might reach the unprecedented total of between 7,000 and 8,000 tons.

MANURING OF TEA.—An Estate proprietor writes:—"There is one thing in Ceylon not half attended to and that is when applying manure either artificial or bulk, to be careful not to let the coolies cut the roots of the tea, the main side roots I mean. I have seen a lot of careless work done in this respect. The tree will expend its energy in making fresh roots using up the manure in the attempt, instead of its going to strengthen the whole tree, and make it flush more freely. For this work mamoties should be forbidden, and forks or a blunted short scraper used. I think it folly manuring tea too when old coffee stumps with feeding rootlets are allowed to remain in the land. These should all be removed if manuring is to be done."

"SOOTY MOLD ON ORANGE TREES" —LESSONS FOR TEA PLANTERS.

Mr. E. E. Green writes from Eton, Pundaluoya, on the 20th August, as follows:—

Thanks for the paper (Bulletin No. 13, U. S. Department of Agriculture) on the "Sooty Mold of the Orange and its Treatment." It has a certain amount of interest to us—as it deals with the black fungus that follows an attack of "bug," and its effect upon the plant. The following points may be noticed:—

1. The author confirms other observers in the opinion that the fungus is quite superficial, vegetating solely on the "honeydew" excreted by the insects.

2. Injury is however found to occur through interference with the process *plytosyntax* (the elaboration of carbon compounds under the influence of light). This fact has been demonstrated by Büsgen:—"He removed the fungous membrane from a small portion of a leaf and exposed the leaf to the sun. In the evening, after a sunny day, the leaf was plucked and the chlorophyll extracted with alcohol. After this the leaf was treated with iodine, and the parts from which the membrane had been removed in every case stained a dense blue, indicating the formation of an abundance of starch, while the surrounding portions of the leaf which were protected from the sun by the fungous membrane, remained entirely uncoloured, showing that no starch was formed." This has a direct bearing upon the practice of growing tea under old coffee. When the latter is infected with "scalebug," the "honeydew" and accompanying sooty fungus will be communicated to the tea leaves below, and though not actually penetrating their tissues, will interfere with their proper function.

The author includes "blighted and shrivelled leaves, and small and dry fruit" in his account of injury due to "sooty mold." But the larger part of this effect is surely attributable to the attacks of the insects that precede the fungus.

In treating of remedial measures also, the author writes as if the "sooty mold" were the main disease, instead of being one of the consequences of a more serious malady. He evidently understands the facts himself, as his proposed remedies are insecticides and directed against the insects; but the case might have been made more clear to the general reader. Such expressions as,—“the treatment of sooty mold by fumigation with hydrocyanic gas”—“kerosene emulsion, which has been recommended for sooty mold”—“resin wash for sooty mold,” &c., &c.—are most misleading.

THE AMHERSTIA NOBILIS.—We see an "Enquiring Globe-trotter" writing to a contemporary to ask if the *Amherstia nobilis* is indigenous to Ceylon. No, of course, it is not. It was introduced from Burma to Ceylon. *The Treasury of Botany* refers to it as follows:—

Amherstia.—A genus of the Pea family (*Leguminosae*) named in honour of the countess Amherst. *A. nobilis* is the only species. It grows near Martaban, in the Malayan peninsula, and attains a height of about forty feet. When in flower, it is said to be 'one of the most superb objects imaginable, unrivalled in India or in any other part of the world.' The leaves are equally pinnate, large, and, when young, of a pale purple colour. The flowers are large, scentless, and of a bright vermilion colour diversified with three yellow spots and disposed in gigantic ovate pendulous bunches. The tree is cultivated in some of the larger English gardens; but, requiring so much space, is seldom met with in collections. The Burmese name of the plant is *Thoca*, and handfuls of the flowers are offered before the images of Buddha.

HOW TO ECONOMISE THE AVAILABLE LABOUR SUPPLY ON OUR TEA PLANTATIONS."

We have just been going over the answers received to our Circular on the above subject. They number between three and four score in all, and some of the more experienced and practical planters in the country are among our contributors, as well as not a few who are known as among the more energetic and interested of the younger generation of planters. We have also one or two contributors from among our local Engineers, these having been invited to say what machinery, inventions or arrangements they would recommend to the notice of our tea-planters as means of economising Cooly Labour. We feel sure, therefore, that the Correspondence will be regarded with considerable attention by Proprietors, Agents and Superintendents, more especially at a time when "economy" is in the air,—the one policy which we hear on every side, as requisite to counteract the effect of low prices and low exchange. It will be remembered that our "questions" covered a good deal of ground, including Estate Tramways, Wire Shoots and other similar labour-saving appliances in field or factory. Then, certain remarks were made about "Weeding" and "Draining" and the cultivation of crops to dig into the soil; while finally certain questions were preferred as to the best means of attracting and keeping coolies on estates, and of saving them from current temptations, or falling into the hands of cripps. Young planters cannot fail to benefit by what their seniors have to say on many of these topics, and still more by suggestions which, though they may not be practically adopted, or even suitable for adoption in all cases; yet are invaluable, because of making young men *think* for themselves on points connected with their planting profession which, perhaps, have not hitherto come specially under their notice. It seems to be generally agreed that the younger generation of planters (as a whole—of course there are exceptions) do not secure the confidence of the coolies to the same extent as their predecessors. "How do you manage to have always as many coolies as you want and on such moderate advances?"—was our question the other day to a manager, not a hundred miles from Dikoya district, and his answer was suggestive as to the great value the average cooly attached to the "master" who listened to his little complaints, quarrels and grievances, and generally treated his labourers as so many children in respect of their dependence on himself in their troubles. As an ex-coffee manager puts the case for the "days of old":—

Ramasamy, Menatchy and little Soondurum, used to get their Castor oil, Quinine, Dover's powder and Turpentine at the hands of their Durais and they—master and labourer—were in touch. Now all that is changed. The Head of the Medical Department gets Knighted, a few coolies may be saved when attacked by some disease that requires special medical care; but hundreds of men, women, and children die of diseases because such were not taken in time, and because the simple dose of Castor oil, Quinine and Dover's powder administered by the Factory Manager becomes obsolete, through these armies of Dispensers and Medical Assistants being let loose on plantations,

Then, as to labour-saving contrivances, have we not in many parts of Ceylon, to learn something from our neighbours in Northern India? For instance, the Chairman at the London meeting of the Jokai (Assam) Tea Company, two months ago, mentioned among other things,—

For years we have been extending our cultivation, replanting old inferior China fields with indigenous plants, thus doubling their value, replacing temporary buildings with permanent ones, improving the accommodation for our coolies, providing good water and laying down light railways and tramways in order to economise labour. We have now about 30 miles of railway and tramway on our estates. A large share of the cost of these improvements has in former years been charged to block; but revenue bore a considerable share of it. On this occasion we have charged the entire cost to revenue. Notwithstanding this we have the satisfaction of being able, after paying the usual 10 per cent. dividend, to add £1,191 to the reserve fund, and to carry forward £987. My colleague, Mr. Lawrie, has lately raised an important question as to the proper method of making up the accounts of a tea company so as to do full justice to the present shareholders, and at the same time to keep the necessary guarantees for stability and security, which are of fundamental importance. Mr. Lawrie proposes that instead of debiting revenue with the cost of maintaining new cultivation on a variable area, no year's revenue should bear the cost of maintaining an area of young tea exceeding 5 per cent. of the mature plant. I think that the proportion suggested would be fully ample to provide for any probable depreciation in the plant. We have still to spend a good deal of money to bring some of our gardens up to the standard of equipment I would like, but taking them as a whole, they will, when the improvements now in progress are completed, compare not unfavourably with any other estates I have seen. * * *

The report expresses some apprehension that, owing to the large number of coolies we have lately imported, taking advantage of the large emigration caused by the famine, we may have more labour than we actually need. I have no fear on this head. The tea plant responds gratefully to good cultivation; an extra hoeing never fails to give an ample return in the quantity and quality of the crop. But besides this safety valve, we have decided to plant a fine tract of about 300 acres which lies on our own railway between Panitola and Kampti-Gwali Gardens, and 100 acres on our Tippuk estate, which is almost all held in fee simple. The abundant supply of labour may enable us to go on somewhat more expeditiously with this work than we would have done otherwise.

Every proprietor is interested in what may be done to conserve the health of coolies, to keep them up to the full working strength, and in all that may save them unnecessary labour. How can coolies in the present day care to abide on plantations which require the carriage of tea chests or even rice-bags for more than a mile, or two or three miles, on their heads or backs? Other things being equal, such estates must suffer a great disadvantage and surely the proprietor who does everything in his power to make work easy for his coolies, to make their lives comfortable and absolutely healthy with an ample supply of good water, must score. We are accustomed to boast of our progress on Ceylon plantations; but where are we to find even on the largest or best equipped in the island, "30 miles of railway or tramway" to expedite carriage? No doubt, on the flat and extensive Assam estates, the facilities for laying rails are much greater; but still, a good deal should be done here in this way, and in establishing wireshoots, to relieve the coolies of work they do not like, and to make the working of certain estates more economical.

How to Economise the Available Labour Supply.

QUESTIONS.

IN OUR CIRCULAR TO PLANTERS AND ENGINEERS.

(1.) Have you had any experience of WIRE SHOOTS, or seeing their working, and do you think them applicable much more freely than at present on estates? Do they damage tea leaf?

(2.) Particulars of any other Labour-saving appliances in field or factory of which you have had experience, or have noted among your neighbours?

(3.) Could small TRAMWAYS 18-in. or 12-in. gauge be applied profitably on average estates to save transport coolies?

(4.) On WEEDING. Has it ever struck you that weeding (both of coffee and tea) was overdone in Ceylon?

(5.) With reference to saving Labour as well as saving soil, would you advise an experiment in less frequent weeding, or in what may be called, selected weeding—that is the leaving of mosses, selaginellas, small ferns, and other such small plants?

(6.) Have you ever tried as experiment in cultivating any crop (of lupines, clovers—N.B., not the *Oxalis*, a common and obnoxious weed like a trefoil—) to be dug into the soil, or would you advise such an experiment?

(7.) Is the present system of DRAINAGE satisfactory? Could any partical means be devised for trapping or retaining the vast amount of soil that is annually carried away with the surface water? A favourable account has reached us of the result of planting rows of cuscus grass (which neither seeds nor spreads) above the drains—these grew close and strong, forming a barrier against soil being washed down, while allowing the rain to pass through.

(8.) Kindly mention any means in other directions in connection with the usual plantation work where Labour might be saved?

Next as to keeping Labour, would you

(9.) Suggest any special perquisites to coolies—is the giving or ground for gardens to each line generally observed—and where not, would it not make them more contented?

(10.) Would you advise the multiplying of boutiques or bazaars—until each two or three estates have their own—in order to prevent coolies wandering a distance and being tempted?

(11.) Are you troubled with a liquorshop in your neighbourhood, and do you think labour would be saved if liquorshops were abolished, or reduced in number, in the purely planting districts?

ANSWERS:—No. I.

DIKOYA.

(1.) I have worked wire shoots for many years, and find them of the greatest use, and most economical in transport of leaf and firewood, and consider they should be used on all steep estates. I don't think they do much harm to leaf if care is taken to have a good buffer at end of shoot, and the leaf taken out of sack as soon as it arrives at lower end.

(2.) I use single bullock carts for transport of bulky manures; they cango on a 5 to 6 ft. road, and amply repay cost of road construction, in yearly saving on application of bulky manures. When applying bulky manures, the carriage from the road to the different parts of the field, should be done by men in sacks; this cheapens application, as they carry more in sacks.

(3.) I have no experience of Tramways.

(4, 5.) I don't think any harm is done when scrapers are allowed. Nowadays with scarcity of labour it is more than ever important to keep estates free from weeds, as an additional inducement to kanganies and coolies, who make money out of their contracts, and it keeps them contented. A weedy estate is harder to provide with labour, unless they have some other compensating advantages.

(6.) I have never tried any experiment of growing clovers, to be dug into the soil, although I think they would probably do good; but for the reasons stated above, relative to labour—I would not go in for it.

(7.) Tea responds well to close draining, and requires closer drainage than coffee used to; if this is well done, I think the loss of soil would not be great. I have never tried planting rows of cuscus grass above the drains, if it could be kept under control, I think it would be advantageous.

(8.) If care is taken beforehand, a great deal of transport can be saved by coolies carrying to and from work, timber, &c., stones for Factory, if building is going on, if it is so arranged that it is ready for the coolies wear where they leave off work; firewood too, can be carried this way, and artificial manure can be carried in light loads by the pluckers from factory to fields nearer to point of application. All this if arranged beforehand, saves putting on special transport coolies, and is no great delay or trouble to the pluckers or pruners going in that direction.

(9.) Coolies like gardens round their lines, but I think it is only the few who take trouble to crop them. Allowing coolies to keep cattle is a great inducement, and it pays to give up some grass ravines for their use, and after building small sheds for their cattle, they are less likely to wish to move.

(10.) No. I don't advise increasing bazaars, the coolies would only increase their debts; but I think it pays to get rice carted each Sunday to the nearest point to the estate, so as to avoid the absolute necessity of all the coolies going to the big bazaars of the district, as there is no doubt, they are often cramped.

(11.) I have not suffered any inconvenience from liquor shops, and do not think their total abolition necessary, though I should not like to see their numbers increased.

DIKOYA.

No. II.

(1.) I have worked a wire shoot for some years, but only used it for firewood, and on the majority of estates, do not think much labour could be saved if used to convey leaf to the Factory.

(4.) I believe strongly in clean weeding and with reference to questions 4, 5, 6 and 7 think that to a great extent, the planting of Grevilleas regularly through the tea meets the difficulty. Planted closely to start with, and thinned out as they increase in size they not only supply a certain amount of firewood, but do good to the tea. They manure the land with the quantity of leaf that falls, reduce the number of coolies required for weeding and prevent waste.

(9.) I believe in giving ground for gardens to the coolies and think it helps to make them contented and to stop on the estate.

(11.) The fewer the liquorshops the better. I find coolies who never drank arrack except at their annual festivals now drink it daily, owing to the proximity of an arrack tavern which benefits the proprietors of the tavern only.

BOGAWANTALAWA.

No. III.—ALAGALA.

(1.) I have had no experience in working a wire shoot, but I have often seen one at work. It might be more largely employed in saving the labour of conveying the morning's delivery of tea to the Factory. I have not observed leaf damaged by the transit. The wire is useful in carrying fuel.

(2.) I have not observed any other appliances worked to save labour. Managers are keen to adopt any such that might arise.

(3.) Small tramways could be profitably employed on Estates of over 500 acres in extent, when the wire could not be used, and when land upon which to lay the tram is free, but upon small estates the expenditure would be prohibitory. Indeed I believe a narrow road for conveying leaf by carts where a wire could not be used would be cheaper.

(4.) Hand weeding it without the use of anything but a small piece of wood would loosen only a trifling

NO. V.—LOWCOUNTRY ESTATES.

amount of soil; using mamoties and weeding once in 3 or 4 months as in the days of coffee, loosens much soil which is carried away to the paddy-fields as in this district, benefiting the paddy growers, and elsewhere into the sea. I do not believe in the retention of weeds, even small ones, for the formation of humus. In weeding by hand, I would only leave moss.

(5) Monthly weeding by hand—there can be no saving of labour upon this; it is most effectual and cheap.

(6) I do not believe in growing anything in proximity to the tea bushes to be dug into the soil—manure is the only thing I should dig in.

(7) I cannot suggest anything in the way of improving the drainage. I have seen cuscus grass planted on roads, but the roots I have found weakening the trees alongside.

(9) Giving coolies garden lots would entail much annoyance to the Superintendent as frequent robberies among the garden holders will arise and on each such occasion the Superintendent would be expected to give redress. By the sale of the produce of the garden coolies will secure money and we know the richer they become the less work will they do.

(10.) Certainly there should be no addition to Bazaars—each addition would mean another source of borrowing by the coolies, the new bazaar would offer greater indemnity than the old one to do so.

(11) Being surrounded by villages where the kitool flourishes, coolies in this district drink the toddy of this tree in preference to arrack—the drink being adulterated with bad tobacco and chunam-lime, it quickly effects the brain. I do not see how the sale of this toddy can be checked.

OLD PROPRIETOR AND PLANTER,

NO. IV. CENTRAL PROVINCE.

(1) We have seven wire shoots working here very satisfactorily. Where the land is steep they are invaluable as labour-saving appliances. They might be much more largely utilised than they are. I have observed little or no damage to leaf where due care is taken. Minor cart roads to end of shoots might be more availed of.

(2) Well-equipped factories are practically complete so far as labour-saving appliances go, but for transport of chests and fuel, where factories are not favourably situated, aerial tramways might be much more largely used.

(3) Tramways as suggested are not suitable on average estates.

(4) & (5) No, distinctly not; clean weeding is absolutely indispensable on all Ceylon estates.

(6) I am starting an experiment with *Seradella* grown apart from tea. Is the *Oxalis* referred to the obnoxious weed defined by Mr. Nock as *Oscalis violacea* belonging to the *Geranium* family?

(7) As satisfactory as the conditions admit of, I do not know of any practical means of preventing loss of surface soil during heavy thunderstorms. I would fear more damage to surrounding tea than benefit from retention of soil by growth of cuscus unless under exceptional circumstances.

(8) Beyond aerial tramways, wire shoots and minor connecting cart roads, I can think of no means whereby labour might be saved.

(9) Ground for gardens for the married and settled old coolies is certainly appreciated, and adds to their contentment. A boutique on the estate under estate control is a decided advantage where the estate is situated far from the market.

(10) As perquisites, weeding contracts at R1 per acre kept thoroughly clean, leaving a good margin of profit to kangannies, and to the coolies payment by results for plucking, that is a rate per lb. or a day's name for a fixed quantity and from 1 to 2 cents per lb. for every additional lb. plucked.

(11) Not troubled with a liquor shop in this neighbourhood, but the illicit sale of arrack and toddy, in the villages some little way off, are certainly harmful and demoralizing. D.

(1) Wire shoots are not numerous in the low-country as the lay of the land is unfavourable. Shoots save labor only on long lines and if carefully placed do no injury to tea leaf.

(2) The actual saving of cost of labor is not so much in the want of appliances but in the getting the day's work done, and the competition is so keen that planters overlook short work in fear lest pressure would induce his men to give notice to quit, hence heavy cost.

(3) Tramways—primary cost and upkeep together with interest on outlay would—only answer on large properties with central factory.

(4) Tea during the dry weather does not appear to suffer from low-growing weeds, but if not cleared and cleaved after the third month, turns yellow and does suffer. This I attribute to surface moisture in undue quantity.

(5) Tea, generally in Ceylon, will not bear the growth of weeds for any lengthy period. The chief feeders are all surface and any surface feeder starves the rootlets.

(6) No, I tried Sea Island cotton around germinated seed and satisfactorily for six months, but had to eradicate it after that.

(7) Drains cut at gradient one in thirty will carry off water and wash is only very heavy rain, but require constant removing of silt which is saved, but the best ingredients of the soil are wanting.

(8) A cooly can only do a certain quantum of work for the day's pay and if this be systematically agreed to, the cost of production will not be excessive. If planters pay different rates of pay and pamper their coolies so that they will not want to quit service, cost of labor must rise.

(9) Coolies who know masters in touch with their men rarely want to quit and contented coolies always ask for plots of ground to grow their vegetables, &c. When this is so, coolies generally live contentedly.

(10) I have tried this and the Tamil cannot compete with the Moormen or Sinhalese boutique-keeper. Wherever estates spring up there the boutique springs up.

(11) Not troubled. A liquor shop is necessary in the district and one legally established is under control. The Tamil will have his liquor occasionally and why not? The Superintendent should have it in his power to suppress excessive drinking.

I have never lost my cool connection since 1857 and have yet one alive of the original kangannies, whose relatives and descendants number 76 here and their pay is today what it was in 1857.

B.

NO. VI.—UVA.

(1) I have not had much experience in the working of shoots and have seen a good many working and am firmly convinced that where practicable they should be erected. If not kept too tight and bags are allowed to come in slowly at end, no harm is, I think, done to leaf, but if kept too tight (the rope leaf is considerably broken by sharp collision at terminus.

(2) Small tramways would, I consider, pay on large estates where manuring is done extensively and where land is of a steep nature.

(3) Yes.

(4) I have always been of the opinion that weeding has been overdone. It is, of course, essential that some weeding should be done and all seeding weeds removed, but all mosses and weeds that do not climb but cling and cover ground should, I think, be left.

(5) Yes.

(6) No, an experiment on a small field of tea would be an excellent idea.

(7) The present system of drainage appears to work satisfactorily in taking the water from the ground; but the amount of soil taken with it is tremendous. The allowing of the selected weeding would do a large extent, I think, to rectify it. If the

cuscus grass were put above drains on steep land where wash is great, it would do good; but on land of the easier lay nothing is required.

(8)

(9) Every estate should set aside a small acreage round lines for the coolies to have small gardens to grow cabbages and the such like.

(10) Distinctly no. The present labour troubles have, I consider, largely to be attributed to the debts run up in the boutiques and the unmerciful prices charged by the boutique-keepers and interest charged on loans made by them to coolies and kanganies on surrounding estates. The farther the boutiques are away from the estate the better. Coolies then only go less often, and though perhaps the estate loses a day by their having to go a distance, it is best in the end.

(11) There are several liquor shops not far distant from here; but other than that coolies have a good deal of secret selling amongst themselves. They do not give much trouble. If the regulation were made in all liquor shops in the planting districts that all liquor were to be drunk on the premises, and the shopkeepers only allowed a license to that effect, it would do considerable good.

C.

NO. VII.—HIGH DISTRICT.

(1) Wire shoots are very advantageous for large estates or groups of estates where the lay of land is suitable. If properly fixed up, damage to leaf should not occur.

(2) Nil.

(3) Certainly not. Initial cost prohibitory.

(4) *Weeding*.—Poor coffee was not given a fair chance in many cases, but to give clean weeding credit for killing it is really too outrageous.

On steep land drains were usually conspicuous by their absence and as on many estates weeding had to be discontinued during crop time, through insufficiency of labour (no new song this you see) and of course weeds grew apace and doubtless for months they helped to prevent wash; but, as they had to be ultimately exterminated by that useful implement yelect a mamotie, during the dry weather tons of soil trickled down the hillsides of its own accord or aided by the gentle influence of a North-East gale and when the rains descended and the floods came, poor old coffee, as well as its planters, felt sick indeed.

Rocky ground has naturally unusually rich soil and rocks tend to lessen wash; so it is not surprising that coffee under such favourable circumstances should struggle through, and I therefore decidedly repeat certainly not, in reply to No. 4.

(5) Certainly not, once more; and as for leaving mosses, selaginellas and ferns which so readily attach themselves to the stems and branches of tea, I would as soon think of advising a fellow to discontinue bathing for his own health's sake and the general pleasure it would provide for his friends and neighbours, as encourage this.

(6) With over-production continually staring us in the face, why try to go one better seeing present results are sufficiently satisfactory for most, if not all, of us.

In any case, I would not advise experiments with lupines or anything else of that sort except on the easiest lay of land.

(7) Where drains have been cut at an easy gradient and are periodically attended to, there is practically no loss of soil. In steep graded drains silt pits would prevent loss.

Guinea-grass was planted in the coffee days to prevent wash and it did so to some extent; but it killed the coffee near it and your cuscus will probably have the same effect on tea or at all events render it unproductive in its immediate neighbourhood.

(8) Nothing to suggest.

(9) Coolies are invariably allowed garden ground and in many instances are permitted to keep goats or even cattle where grass is plentiful or grazing lands are on or adjacent to the estates: so what more they can want to make themselves comfortable I fail to see.

(10) A multiplication of bazaars would do no harm, more especially if run on co-operative principles but what is to prevent the tempters from frequenting these and moreover Ramasamy, like a sensible man, wouldn't trust his own mother further than he could see her—so I fear the co-operative idea is impracticable.

(11) Liquor shops are an abomination and lead to breaches of the peace and such like and should therefore be discouraged; but there is no means of preventing the illicit sale of liquor in the lines, in a quiet sort of way, as the low-caste cooly nowadays insists on having his stimulants.

On the whole I think your queries might be answered thus:—What is, is best.

"FARMER"

NO. VIII.—LOW COUNTRY.

(1) I have had no experience of wire shoots; and my observation of them has been very occasional and superficial, as I am seldom in the hill country.

(2) None.

(3) Small Tramways, I should think, could be profitably used only on Estates of considerable extent where labour is scarce. Original cost is the stumbling block.

(4) It always struck me that weeding was overdone on steep coffee lands, as on Tea. The few weeds industriously scraped off could do less harm in exhausting the soil, than the scraping in helping it to be washed off. The pulling out of strong weeds should generally do.

(5) Yes; less frequent weeding of the surface weeds, involving selected weeding. That is, the deep strong weeds would be taken off regularly, and the others at less frequent intervals than now. Their retention always, especially in damp and shady fields, would sour the soil.

(6) No experience; but would not the success of cotton (some years ago) with Tea on some estates, justify experiments?

(7) In the absence of experience in the hill country, I hesitate to offer an opinion; but it has often suggested itself to me that traps should prevent the carrying away of much valuable soil. Though the wash is less in the lowcountry, I have silt traps, and have also found cuscus useful in rugged patches and on broken ground.

(8) No suggestion to offer.

(9) Certainly, a patch of garden to each set of line would be an advantage; and I always regard the beginning of horticultural operations with pleasure, as suggesting a comparatively permanent settlement. Gifts of cloth or cash to the best workers on the estate, on *peranals*, are highly appreciated. Rs 50 to a Sinhalese for his poll-tax was welcomed as a royal gift.

(10) The less boutiques the better, unless the keeper is a good man, or can be bound down as your tenant to give no credit. Indebtedness is the cause of much unrest, and perhaps bolting.

(11) I am not troubled with liquor shops; but the illicit sale of toddy and arrack is a nuisance. Taverns at regular intervals are a necessity. The cooly likes an occasional drink; and if he cannot get it fairly, as master does, why?—he must encourage the illicit uncontrolled seller.

F.B.

Siyane Korale, Aug. 10.

NO. IX.—SOUTHERN DISTRICT.

(1) It has long been recognized by planters that wire shoots are most helpful in the working of an estate, and that in the long run they greatly reduce the cost of expenditure in the transport of leaf, firewood, manure, &c., and on estates where the lay of the land is suitable, feeders to a main line of wire are easily adjustable; and the more this principle is adopted the greater will be the saving in labor. As regards damage to leaf, this could be avoided, if the gradient at the terminus be so arranged as to diminish the fall, and prevent the loads coming down with too great a shock.

(2) While wire shoots can be only used with advantage on comparatively steep land; on those estates where the lay of the land is fairly level or gently undulating, wheeled traffic, in the shape of light carts, made suitable for round roads, and drawn by ordinary native cattle, could be used with the greatest advantage.

(3) Tramways could not be used on the average number of estates, which are mostly steep; but on a percentage of them, where the lay of the land is suitable, *i.e.*, practically flat, 12" or 18" gauge tramway might be laid down, proving very beneficial and a great saving of labour. It must, however, be understood that individual capitalists could hardly be expected to gain from such an undertaking, as the initial cost would be prohibitive; but to a Company, with capital at their back, such a scheme would undoubtedly commend itself, and be found workable.

(4) The system of weeding adopted and carried out in Ceylon for so many years with success has proved itself to be the right one, and to change it now would, in our opinion, be unadvisable.

(5) Mosses and ferns might be left unweeded to a certain extent, but care should be taken to prevent them from spreading too thickly over the ground, as moss, especially, has a tendency to not confining itself to the ground alone, but of encroaching upon products in its immediate vicinity.

(6) We have never tried the experiment of cultivating any crop of lupines, &c., between the tea, so as to prevent wash, and hardly think it would be likely to succeed.

(7) We are of opinion that it would be unadvisable to effect a diminution in the system of drainage of estates as at present carried out. In preference to cuscus grass, a close hedgerow of tea, planted immediately above each drain, would be found serviceable as well as remunerative.

(8) The only other way we can conceive for reducing manual labour, is the introducing into factories of the latest approved machinery; and if some ingenious person—yet to be born perhaps!—would invent an effective Plucking Machine, it would reduce the labour requirements of estates by at least one-half, to say nothing of the vast reduction in cost of production which would ensue, which, at present prices, is principally what we have to strive for.

(9) Coolies are as well off as they possibly can be in this respect, and we consider that the granting of any further perquisites or indulgences would not make them any more contented but rather the reverse. Volumes could be written on this subject were time and space not limited.

(10) We believe in groups of estates having their properly established rice stores and boutiques immediately under the supervision of the Superintendent. The ordinary boutique-keeper, who swindles the cooly out of his hard-earned wages, and encourages him to indulge in extravagance, is the man who is lining his pockets at the expense of the country and is without doubt the curse of the planting industry of Ceylon.

(11) Indiscriminate licensing of taverns and liquor shops in planting districts is another fruitful source of injuring our labour supply, and Government have a deal to answer for in this respect. Illicit drawing and sale of toddy and arrack is another crying evil, which should be put down with a high hand by the Powers-that-be.

TWO OF THEM.

REVIEW OF LETTERS NOS. I. TO IX.

The questions which we have propounded by circular to planters and others on the above subject, are not only supplementary to those which have been most useful in eliciting information on the cultivation and manufacture of tea in all their branches, and on the conditions which have affected the price of tea in

the markets of the world, but they may also be regarded as naturally flowing from the answers which have been published in response to our first circular. It may be remembered that, in those letters, the cry from district after district was, that labour was scarce; that the scarcity rendered the application of manures difficult, if not impossible; that even where there was sufficient labour, it deterred many from applying manures because of the probability that the labour would not suffice for the heavier crops which would follow manuring; and, perhaps most important of all, that it led to plucking at longer intervals, thus rendering coarser plucking, rasping liquor, and the preponderance of lower grades inevitable. In these circumstances, and with so serious a weight of testimony on the direct and indirect drawbacks of an insufficient labour supply, it became necessary at once to inquire, how can we increase our labour supply? Or, how can we utilize to the best advantage that which we have? The difficulties which beset recruiting have been well-known and appreciated by the planters and the Government for many years past; and in recent times they have been the subject of anxious inquiry, without in any way improving the outlook. That, however, is not of direct concern in the present investigation; but even if it were possible to draw on the labour reserves of India according to our needs, the duty of economizing what we have would yet remain. And especially necessary is it that we should make the present supply of labour suffice, in view of the shrinkage of profits caused by low prices, the upward tendency of exchange, the dearness of rice, and the growth of so-called cost advances, much of which, we fear, are all absolutely irrecoverable, and to which much more will have to be added if our labour force is to be permanently increased. It is these and such like considerations which weighed with us in framing the questions to which we have already received a very encouraging volume of answers.

We purpose drawing attention now to the first nine letters which we give above. The testimony in favour of wire shoots, as a labour-saving appliance, comes from all who have tried them—Dikoya, Bogawantalawa, "C" from Uva, "Farmer" from High District and "Two of them" from a Southern District, certifying from experience to their economy in the transport of manures, firewood and tea-leaf; while others who have no personal knowledge of "shoots" have observed their satisfactory working; and all seem agreed that their use might be greatly extended, especially on steep estates. Now hire is a most important means of economizing labour, which has long passed the experimental stage—it was in use in the palmy days of coffee quite a generation since—and which comes to us with the highest credentials. Why is it not more largely in use? For, as "B from Lowcountry Estates" shrewdly points out, it is not only the direct saving in the cost of transport which has to be considered, but the setting free of labour for other urgent work which must be done, and the ability to exact a fair day's work for fair wage where it is not necessary to humour coolies for work which is distasteful to them, and of such work, carrying loads unquestionably is one form. The only doubt that is felt about wire shoots is connected with damage to leaf; but all our correspondents are agreed that there need be no damage, if the wire is not stretched too

tight, if there is a good buffer at the end of the shoot or the gradient is not too sharp, and if the sacks are emptied promptly as they arrive. Where necessary, single bullock carts have been found most useful in the transport of bulky manures to the fields to which they have to be applied, into which such can again be carried in sacks if *men* are employed, as baskets hold less. Tramways do not appear to find favour on account of their heavy initial cost; but on large estates of 500 acres or more it is admitted, they would be found useful and would probably pay for their cost. On small estates, a road and single carts will be found more economical in the opinion of "Old Proprietor and Planter."

On the question of "Weeding," there seems to be a considerable difference of opinion; for though clean weeding commends itself to a majority, as justified by experience, one admits that damage is done when scrapers are allowed. Some insist on hand-weeding alone, some would allow mosses and ferns to remain; some regard these as dangerous; while only two "C" from Uva and "F. B." from Siyane Korale declare that weeding has been overdone. The weight of opinion, so far, is therefore decidedly against any interference with the hoary system, which is further commended as helping to humour kanganyies who make money out of weeding contracts, and the evils of which may be guarded against by careful drainage. But "Bogawantala-wa"'s suggestion has the merit of serving many purposes, and of apparently covering five out of our eleven questions—that grevillias should be more extensively planted than now, and be gradually thinned out as they overshadow the tea. The advantages are that the shade will reduce the weeds, the litter of leaves will serve as manure and prevent wash, while the thinned out trees and the prunings should supply firewood. Subsidiary crops, whether for profit or to be dug in as manure, do not find favour with our first batch friends. Lack of labour and the fear of wash are the chief considerations urged against any turning up of the soil; while "Farmer" preaches contentment with results which are "sufficiently satisfactory" without any adjuncts to tea. That is just begging the question; for if all are as prosperous and happy as our friend seems to be, inquiries like those we have initiated would be wholly unnecessary.

All our correspondents are practically agreed on the advantage of allowing coolies garden plots for vegetables, &c. Not only is a garden a source of profit and of health to coolies—vegetables in too great abundance cannot be consumed by those into whose diet dried and salted fish enters largely—but it keeps them from mischief when "absent," and binds them in a very desirable way to the "tottum" or "wattie." It is particularly satisfactory to find so great agreement among planters as to the necessity of being in touch with their coolies—a point not sufficiently appreciated, we fear, by many of the new generation. A kind or jocular word, patient attention to some trivial complaint, sympathetic notice of a minor ailment:—all these go a great way to cheer the Tamil immigrant labourer and make him content with his lot, and even to prevent quarrels and misunderstandings in the lines. "B" says that he has never lost his coolly connection since 1857; and he yet numbers among his kanganyies one of the original lot, whose relatives and descendants on the estate number 76 and are

satisfied with the rate of wages they got 40 years ago. Surely that is remarkable testimony to the importance of good relations, and "B," like most of the others, does not believe in enforcing abstinence from arrack. A licensed tavern can be controlled; its abolition would be almost certain to lead to unchecked illicit sales.

(*Letters Continued.*)

No. X.—NORTHERN DISTRICT.

WIRE SHOOTS.—I have worked these for many years and use them for all purposes, viz. (1) sending down firewood, (2) tea leaf in coir bags, (3) jungle soil for manure in gunnies, etc., etc. If lots of packing are placed against the delivery end, the leaf will not be much damaged, but if left to strike the tree or rock to which the shoot is attached the leaf will to a certainty be very much bruised.

OTHER LABOUR SAVING APPLIANCES.—Aerial tramways are undoubtedly foremost in this respect, and another few years will, I am sure, see many more erected in the tea districts. Terrestrial Tramways are out of the way, except on places like Mariawatte, and there Appuhamy and his bullock cart would be as efficient and much more cheap.

WEEDING.—Surely this question has been threshed out long ago. A clean estate or none at all. There is no doubt "humus" is what our poor clayey Ceylon soils want, and no better way to obtain a supply is to grow a thick crop of some nitrogenous weed, the same to be cut down and forked into the soil before it seeded. But look at the labour it would require, let alone the thousands of obnoxious weeds that would grow and seed unseen among the sort you were raising! Who is there bold enough to try? Such a beneficial green manuring would work wonders and make our soil last for years to come. An American plant called the Californian Cow Pea is what should be used for this green manuring. See back numbers of the *Tropical Agriculturist*.

DRAINS.—If the cross and centre drains now in use all over the tea districts are properly attended to, no better plan for the mouey we can afford to spend on this head can be employed. I know of estates where every coffee tree was terraced, and every roadside built up with hammer-dressed stone over hundreds of acres, until the land looked like the ramparts of Malta. This work was done splendidly many years ago, and it would be very interesting to know if the tea now growing on this land is better than what is growing on other and unterraced fields on the same estate. The capable Superintendent of Spring Valley Estate, Badulla, could say so if he liked.

COOLIES.—The possession of small gardens round the lines undoubtedly serves to make the coolly contented; but it won't deter him from leaving the estate if his kangani orders him, or if he wants to go himself. It certainly adds to his health.

BAZAARS.—Each estate should have its own bazaar if possible, under the fatherly supervision of the Superintendent, and owned by the head-kangani. The evil results arising from coolies going long distances to bazaars for their curry-stuffs, etc., are incalculable. They come across crimps and pimps, and bullies of every sort, get into gambling hells, and get drunk and are most likely robbed and beaten. I am now building a big kaddy on this estate which I hope to get my coolies to come to in future instead of going weekly to that den of iniquity, Huluganga.

LIQUOR SHOPS.—The arrack tavern is an evil we must all put up with, but liquor shops are the very mischief. In these shops the better class of cooly, the conductor and tea-maker go and booze and get corrupted. Otherwise they would not drink as they are ashamed to stand and drink at the arrack tavern with the common herd.

L.

No. XI.—UVA.

* In replying to your questions I must premise that for all practical purposes we have plenty of labour

in these parts. Occasionally, of course, we are a little rusted, but speaking generally we have a sufficient labour force and advances are small on the estates. I manage about R2 per head.

If it is asked how it is this state of Arcadian simplicity exist I would say it is due to several causes.

For one thing most of the Managers have been on their estates for a long period, from 5 to 15 years, and are well-known to the coolies. For another, (but let no whisper of this be heard beyond the editorial sanctum,) there is still coffee on our estates and Ramasamy dearly loves a fragrant cup in the morning and I fancy generally gets it!

Then most of our places being still in the transition state from coffee to tea, it is not yet altogether a matter of producing so many pounds of tea at so much a pound; we have our coffee to prune, our cinchona to cut out and our clearings to open and the cooly has more variety in his work.

Having said this I will only reply to a few of your questions:—

(1.) Have no experience. As regards their damaging leaf I fancy they do, but the test is what prices do those obtain who use them?

(4.) In theory, Yes. In practice, No.

(5.) I have known less frequent weeding tried on several estates and it has always ended in the place having to be cleared up with mamotics to the permanent damage of the property.

Leaving mosses and ferns was tried on a well-known estate in Dimbula and the coffee went back rapidly much more so than on the clean weeded portions of the estate. I have not seen it tried with tea.

(7.) Not at all satisfactory. The planting of cuscus grass sounds worth trying.

(9.) Certainly all coolies should have gardens if they want them.

(10.) At first sight this would seem a move in the right direction, but care would have to be taken as to who held the strings in the estate boutique, or the last state might be worse than the first.

(11.) Liquor and liquorshops are an unmitigated curse to our labour force; but under the present system all that can be done is to try and get a shop closed here and there. A benevolent Government having carefully fostered a taste for liquor for generations now says to us:—"There is no use in curtailing facilities for obtaining drink, for if we close our licensed shops there will be illicit sale." And so it is, but whose fault is it?

NO. XII.—MEDIUM DISTRICT.

(1.) I have seen wire shoots used with great saving of labour on large steep estates: in one case a transport of 5 miles is saved by means of 3 shoots which take the leaf to the store in twenty minutes. Leaf is not damaged provided it does not arrive at the bottom of the shoot with too great a speed, which can be checked in the case of steep shoots by means of a siding or "shunt" when the leaf is caught.

(2.) Hill tramways where spare power is available are useful for transport of chests, etc., from factory to road, if the former is not on cart road, and is yet within a reasonable distance of it.

(3.) I do not think small tramways would pay on average estates.

(4.) I do not think weeding is overdone on properly drained estates.

(5.) I certainly would not advise less frequent weeding or "selected" weeding; the latter would be much more expensive and require very careful supervision to see that only the proper weeds were left: less frequent weeding would mean less profit to the contractors, and kanganyies will not stay on an estate where they make no profit on contracts.

(6.) I have not tried the experiment.

(7.) The present system of close and rather gentle gradient drains is a great improvement on the old system of steep and rather far apart drains. I find drains with a gradient of 1 in 34 or even 1 in 30

about 26 to 30 feet apart on steep land save the surface soil excellently. I have not tried cuscus grass in the way suggested.

(9.) I strongly recommend a small portion of ground for gardens being given to coolies round every set of lines, I find it makes them much more contented.

(11.) The number of liquor shops in this neighbourhood is far too great; undoubtedly labour would be saved if they were abolished or even reduced in number. Drinking is increasing very much among the coolies; after every pay day fully twenty-five per cent of the men don't come out to work until they have drunk all their pay. A.

NO. XIII.—MATALE NORTH.

(1.) I should say Wire Shoots would not be suitable for conveyance of produce.

(2.) A hill tramway might save time and labour on a large estate, and be economical when there was good water power.

(3.) I think ordinary tramways too expensive for Estate use.

(4.) I think the present system of clean weeding is the best and most economical.

(5.) The more general growing of shade would certainly render the working of an estate much cheaper, and therefore reduce the necessity for labour considerably. Weeding can be thus reduced by 30 per cent; when trees are selected from which there is a heavy fall of leaf, wash is almost done away with, and drains require little attention. The constant fall of leaf also is undoubtedly good for the soil and in time renders old worn-out soils fertile.

(6.) I think good comfortable lines and plenty of them have a good deal to do with making an estate popular and certainly improve the general health of an estate. An estate caddy is an advantage; but the keeper of it must be closely watched and there is a good deal of trouble attendant on one. A liquor shop is probably an evil that must be tolerated, but if the duty was raised on arrack very considerably it would check drunkenness to a great extent. My opinion however is that no great change for the better will take place in the labour supply until the pay of the cooly, not the Kangani, is raised all round. We have now heavy competitors for labour which we had not before, and yet we are actually paying the individual cooly less than we did 20 years ago. The pay of a good cooly in the coffee days was generally 37½ cents; of a good woman 27 to 29—against 33 and 25 at present; the coolies then, in crop time earned large amounts for extra and cash pickings, at least as large as are earned for extra plucking now—and living was cheaper.

(7.) The present rate of pay is adhered to, because tea has to be put into the market at so many cents per lb.

(8.) The Superintendent therefore has to make it up in advances which become so large that they in many instances can never be recovered, and the cooly gets to think far more of his advances than his wages. Such a system is rotten and cannot last. M.

NO. XIV.—UVA.

(1.) Wherever the gradient would allow wire-shoots are most valuable money savers; don't damage tea if sent in coir bags and packed loose.

(2.) —(Nothing; on other appliances.)

3 If cost is not too heavy. In Ceylon we must have practically no weeds or quantities, but tea is partially a weed killer; care should be taken to prevent surface being scraped.

(4.) Yes: (weeding overdone).

(5.) Our present system is good enough if scraping is fought against.

(6.) No (Experiment tried to cultivate lupines, etc. so as to dig in.)

(7.) Can't say. (Drainage).

(9.) Coolies now go to the highest bidder at the command of the Chetty. He was a free agent; but is now a slave to the Chetty and however much he loves his

home they force him to move on to another if his master will not yield to extortion.

(11) Arrack taverns are a curse to the estate labourers and the Arrack renters seem to encourage illicit-sales and Headmen don't try to stop it. R.

No. XV.—MEDIUM DISTRICT.

(1) We have a large number of wire shoots and find them labor-saving and economical. The leaf is injured to some extent in them.

(2) Wire overhead tramways in the absence of cart roads meet all requirements of transport to or from the estate and it is surprising that they are not more generally used.

(3) The expenses of rail tramways would be prohibitory, on most estates.

(4) We believe in keeping the estate thoroughly clean.

(5) The mosses do not seem injurious to tea on well-drained land.

(6) No. (See above).

(7) Where the lay of the land permits, drains cut at a low gradient—say one in twenty to one in twenty-five, so as to permit the water to drain off slowly,—seem preferable to a steeper gradient which scours and carries off the loose soil with it. This does not apply to steep land and the drains must be deep.

(8) For transport of fuel and leaf, wire shoots on steep land and traced roads over which light carts can be taken on flatter land, are all that occur to us as applying at all generally.

(9) On estates not at a high elevation the more open the surroundings of the lines the better on sanitary grounds. Space for gardens is generally left; but is more often than otherwise neglected by the coolies; plantains and perhaps a few brinjals flourishing in the accumulated filth. Lines should be built wherever practicable near a good supply of water and where there is a slope in all directions from them. Where practicable the keeping of stock should be encouraged.

(10) Boutiques in close proximity to the Factory leads to pilfering; on the other hand coolies should not have far to go for their curry stuffs.

(11) We have no liquor shops near the estates; but illicit arrack selling goes on everywhere. T.

No. XVI.—NORTHERN DISTRICT.

(1) About $\frac{1}{2}$ of my leaf is brought in by means of Wire Shoots. I think they are very generally used. I do not see how any injury to leaf can occur with ordinary care.

(2) Wire tramways are being used on several Estates to bring tea to cart roads. Few Estates in Ceylon are large enough or flat enough to make a 12" or 18" tramway of service. But it would be an advantage on some in the low country.

(4) The cheapest Weeding and therefore that which occupies the least number of coolies, is undoubtedly the monthly contract system, which if properly carried out can be done for R12 per annum per acre or even less. Viewed as saving expense not a fern or a moss should be spared, as they would soon form seed beds for other weeds. In damp climates, moss would, if left, soon choke up the trees and spaces under them and make the bark of trees unhealthy. The cleaner the Estate, the less the soil is disturbed and the less "wash."

(5) No—not because I think that less frequent weeding would do harm to the tea, but because it would be more expensive. Even if dug in (where the nature of soil admitted) twice a year, it would be expensive and require more labourers.

(6) Quite, when thoroughly done. I would not plant anything in good Tea, but in bad, and on exposed ridges, Grevilleas if not too close are undoubtedly beneficial and make weeding cheaper.

(7) I know of none.

(8) They are too well paid already: the facility with which they can get advances is the great evil.

(9) No. A shop in the Lines has been worked well in some instances, but it generally falls into the head-kangani's hands.

(10) Yes. Abolishing liquor shops or their reduction would (if it were possible) undoubtedly increase the efficiency of the force we have; nearly all coolies drink; and many a gaug is lost from drunken quarrels.

T.

No. XVII.—MID-DISTRICT.

Your circular to hand opens up a very wide subject—or rather series of subjects—to which it would be difficult to reply within the limit of the lines allotted to each question.

(1.) I have no personal experience; but believe the use of Wire Shoots to be capable of very great extension and improvement.

(2.) Have no experience of Factory work. Have used "Thompson's Patent Tea Pluckers" on new flush after pruning, with a considerable saving of time and labour; but hand plucking is found to be more satisfactory after the first two months. With an insufficient labour force these clippers should certainly prove of value as a labour-saving appliance.

(3.) I consider that Tramways (on the ground)—even of the smallest gauge—would be impracticable on by far the larger number of Upcountry estates,—chiefly owing to the difficult nature of the land and the costliness of construction. But overhead haulage tramways (with wire shoots) might—and probably will—be more largely employed as labour difficulties increase.

(4, 5.) I am very strongly of opinion that WEEDING has been and is being overdone in Ceylon. I am convinced that vast sums have been thrown away on injudicious weeding; the labour and expense being not merely wasted, but employed to the actual detriment of the property. The result of overweeding is everywhere visible in bare red soil divested of every particle of humus and affording no lodgement for fresh accumulations of leaf-mould. With the surface soil went the coffee. Tea being a deeper feeder is not so absolutely dependent upon surface soil; but how much it is benefitted by the presence of humus is amply evidenced by the more flourishing condition of tea bushes immediately surrounding a well filled weed hole.

On steep land, the Indian method of hoeing in the weeds every two or three months would be quite out of the question. Such a plan would soon transfer the remainder of our soil to the low-country. But a system of water holes between each 4 trees, into which the weeds, at the periodical (bimonthly?) handweeding, would be thrown and allowed to rot, would in my opinion produce good results. It must be remembered that weeds returned to the soil in this manner not only give back what they took out of the soil, but actually enrich it with the store of nitrogen that they have extracted from the atmosphere.

At the same time there are certain mosses and other small plants that might be encouraged to assist in the formation and retention of humus,—serving also to minimise wash. There would be no question of the necessity for artificially manuring tea if nature were allowed to play her willing part in helping to renovate the soil. The favoured plants should of course be selected with discretion. Such as have light surface roots and do not form too matted a growth being preferable. I have here a plant admirably suited to the purpose. I have submitted specimens to the Director of the Peradeniya Gardens for identification. The "Liver-worts" (Marchantia), amongst the moss-like plants, are not suitable, for the reason that their very close growth would interfere with the proper aeration of the soil. The advice of an economic botanist—to test the plants and inform us which would best enrich the soil—would be valuable. Possibly Mr. Willis may give us the benefit of his scientific knowledge.

(6.) I believe that no systematic experiments have yet been made in Ceylon in growing leguminous crops, to be dug into the soil. I fear that this would be open to the same objection that arises in the case of the Indian plan of hoeing in weeds. It might, however, be tried in connection with the system of water-holes suggested above. In districts

where gram is cultivated manurial experiments might be made in the use of the stalks and leaves after the removal of the grain. I believe very good results were obtained in India some years ago, by the use of the leaves of *Acacia decurrens* and *dealbata* as green manure. The trees were grown in waste places and cropped periodically, the leaves being placed in open holes in the tea and allowed to partially rot before being covered up. I know from experience that the fallen foliage of these trees forms good leaf-mould more rapidly almost than any other kinds. Grevilleas shed an enormous amount of leaf; but it takes a very long time to decay and form soil. I do not think that we make sufficient use of material existing close at hand—in the form of coarse weeds and small scrub growing in ravines and waste land. All such green stuff thrown into the open holes and allowed to rot would form valuable accumulations of leaf-mould. It would be advisable to let the stuff rot in open holes until the sour stage of fermentation is over. If it is thought necessary to cover the holes at once, a little lime might be included to neutralize the acidity.

One argument that I have heard propounded against a reduction of weeding is:—"How could we satisfy our labour force, if we reduced or took away their weeding contracts?" But while greatly minimising the cost to the estate, a reduced system of weeding could be made to leave as large or even a larger margin of profit to the weeding contractor. To give an example:—Say that under the present system of monthly hand weedings a contractor has to weed a 30 acre field for R45, employing 6 coolies in the work. These coolies cost him—at an average of say 30 cts.—R1.80 per day, or for the 20 days on which they would probably be weeding, a total of R36 leaving a profit of R9 per month. With a bimonthly selective weeding the same contract could be rated at R30 per month, and 3 coolies would cover the same ground in the time, at a cost to the contractor of R18, leaving the large balance of R12 for his profit.

Of course under any such system we must resign ourselves to a less trim appearance of our estates. These weedless expanses, that have been considered the acme of good cultivation for so long and have cost such endless trouble and expense, would please our eyes no more. But surely, if it can be conclusively proved that a reduced expenditure in this particular is accompanied by an increased efficiency, no one would be willing to pay so largely for mere appearances.

(7.) I have long thought that our elaborate system of DRAINAGE—as at present carried out—is merely an ingenious plan for enriching our native neighbours' paddy fields at the expense of our own property. The amount of soil carried off by every shower can be partially gauged by examination of a drain that has been temporarily blocked by some fallen stone or accumulation of tea prunings. What is wanted is some arrangement for checking the flow of surface water to allow of the deposition of the soil in suspension. I have tried the plan of growing cuscus grass above the drains. It answers most admirably from a mechanical point of view; but there is the objection that it is itself feeding upon the soil that it has saved. This grass is certainly a greedy feeder. Some part of the loss might be returned to the soil by repeatedly cutting the grass (a process advisable also to prevent interference with the tea bushes) and using it as a surface mulching. This plan has certainly one strong point in its favour. It affords a great saving in labour and expense in keeping the drains clean. Since the planting of this grass some four years ago—these particular drains have not once had to be cleared out. Not a stick or stone can pass the barrier, and the soil above the grass has gradually accumulated to a depth of at least 18 inches. I have also tried rows of cuscus grass instead of drains, with similar results as to trapping the soil; but here the volume of water increases as it gets to the bottom of the slope and is apt to score up the ground too

heavily. An ideal system would be one in which the barrier is formed of non-growing material, but sufficiently permanent to last without need of repair for at least eighteen months. Could we not utilize our tea-prunings for the purpose? At present they cumber the ground and add to our difficulties by blocking up the drains. Bundles of the green prunings might be fastened by stout pegs in lines following the course of, but about two feet above each drain. Or the prunings from each bush might be similarly pegged crossways below each plant, forming a series of small breakwaters which would catch and retain any drifting soil.

Your remaining questions, I will leave to others who have studied those subjects. I have already occupied too much space over the earlier items of your circular, which are those in which I have more particularly interested myself. G.

P.S.—With reference to my above remarks on "Weeding," I am now able to give the name of the small plant which I there considered to be "admirably suited to the purpose." Mr. Willis informs me that it is an "*Elatostemma*." Mr. Willis has also drawn my attention to a small clover-like plant—the roots of which bear the nitrogen-fixing tubercles—which he considers would be a most suitable plant to grow amongst tea.—G.

P.P.S.—*Firstly*.—The name of the weed suggested as suitable for cultivation amongst tea for the purpose of preventing wash and loss of soil is *Pilea microphylla* (not *Elatostemma* as stated in my last communication). I see that this plant has an asterisk beside its name in Trimen's Catalogue of the Flowering Plants of Ceylon—which indicates that the species is an introduced one and more or less naturalized in this country. I have frequently seen it grown in English greenhouses as an ornamental rock plant.

Secondly.—With reference to my suggestion that tea prunings might be pegged down along the upper side of each drain, to catch the soil. Since making the suggestion, I have tried the plan—and found it wanting in practice. It answers admirably as long as it lasts; but it is not sufficiently permanent. As the leaves and twigs decay, they get dispersed, assisted by the careless foot of the working cooly, who will not take the trouble to step over the trifling barrier.—G.

PLANTING NOTES.

GROW FRUIT.—A Capetown farmer has obtained 36s. per 100 for fine peaches and 63s. for best pears. A prominent man has just purchased 11 adjoining farms near Paarl, and his first order has been for 200,000 trees.—*Natal Mercury*.

COFFEE PLANTING IN COLUMBIA.—The vast production of coffee in Brazil is affecting coffee prospects everywhere. A consular report on the trade of Columbia contains the following from Barranquilla:—"Coffee cultivation has progressed favourably this year. Some 250,000 bags have been received in Barranquilla during 1896, against 190,000 bags during 1895. Of the coffee received this year about 214,000 sacks have been already shipped, and the remainder will be despatched within a couple of weeks. The coffee exported in 1896 is valued at £987,192. Growers have felt a certain degree of uneasiness on account of the depression in prices in foreign markets which has been experienced since the early part of this year. This depression is attributed to an excess of production in the Brazils. Fortunately the greater part of Columbian coffee is of the finer class, and the fall in price in it has not been so heavy as in the more ordinary qualities. The Government of Columbia has decreed a considerable reduction in the export duty paid on coffee, and should the decline in value continue this duty will be taken off altogether. The new coffee plantations alluded to in last year's report as being under operation, in Tolima and Antioquia, will be proceeded with. On the slopes of Sierra Nevada, near Santa Marta, several large plantations are in course of formation, most of them aided by British capital.—*H. & C. Mail*, Aug. 2).

DENATURALIZATION OF SALT AND ITS USE IN AGRICULTURE.

We are now enabled to give the translation of some portions of the German papers sent to us by Mr. Coomaraswamy's friend, Herr Lange.

These papers consist of:—(1) The Law concerning the Levy of a Salt Tax for the North German Confederation; (2) The Ratification of the same by the several Confederated Powers by name, whereby it came into operation from Jan. 1st, 1868; (3) A pamphlet of 62 pages explaining in detail the carrying out of the Law for a Salt Levy of July 5th, 1888, with exact directions for the several parties concerned as to collection, valuation, exemptions, also giving sample forms for the various registers to be kept by the owners of mines and works or by the Customs' officers in charge of the Levy in the various States. These are prepared for a European country with abundant means for checking and testing at every turn, and could not be adopted here; but we give enough of the paper to enable one to see that the same principle might be applied under simpler forms.

Of course the most important question, from a local point of view, has reference to the denaturalization of salt. Are the agents prescribed available, and can they be practically applied locally? On this point we thought it well to have the opinion of our local Analytical Chemist, Mr. M. Cochran, and it is very satisfactory to learn from him that he sees no practical difficulty. He writes as follows:—

"Most of the substances mentioned for denaturalizing the salt for manuring purposes could be easily and economically applied in Ceylon in the proportions stated, more especially charcoal, coal dust, soot, coconut oil, sulphate of iron or green vitriol; the latter is a cheap substance and a manurial and disinfectant value are claimed for it besides."

It only now remains for the Tamil Representative, who has been the means of raising the present discussion by introducing us to his German fellow-traveller, to bring the whole question before the Legislative Council. He will no doubt be warmly supported by all the members interested in planting and agriculture, who, in a colony like this, we may say, include the whole Council, both official and unofficial.

Probably the wisest course would be for Mr. Coomaraswamy to propose a Sub-Committee of the Council to consider the question in its various issues—practical, fiscal and agricultural. Evidence could be taken from those best able to give the useful information and Papers could be examined, and the resulting Report would, we have no doubt, guide the Government in arriving at a fair and liberal decision on the whole question.

Some little time ago, we mentioned how the discussion on using salt for agricultural purposes was first raised in the "sixties"; but we have now come on an earlier reference, being a letter from Mr. Tytler, dated 25th October 1853, which will be found reproduced on another page.

The translations from the German are as follows:—

LAW OF THE NORTH GERMAN CONFEDERACY

(NO. 1) LAW CONCERNING THE LEVY OF A SALT TAX, OF OCT. 12TH, 1867.

We William, by the Grace of God King of Prussia, &c., order, in consequence of the agreement of

May 8th, 1867, entered on by the States of the German Levy and Trade Union concerning a Salt Tax, we order the following law in the name of the North German Confederacy and Imperial Diet &c.:—
ABOLITION OF THE SALT MONOPOLY § I.

The exclusive right of the State (as now existing) to carry on the trade in Salt is herewith and hereby

INTRODUCTION OF A SALT TAX § II.

Salt destined for inland consumption is subject to a tax of 2 *Thalers* per *cwt.*, nett weight, which where the Salt has been procured inland, must be paid by the producer or owner of the mine; but where the Salt has been brought in from other lands not belonging to the Confederacy, the introducer must pay the levy.

Under Salt (kitchen-salt) are included, beside the made or common and the sea-salt, all salts from which salt is usually separated; the head financial authority of any Confederate State is however empowered to allow such products to go free if there is no fear of a misuse of the same.

I. TAX ON INLAND SALT. I. NOTICE § III.

The procuring or refining of Salt is only permitted in the Salt Works, Mines and Refineries now existing and which have been at work at least six weeks before the promulgation of the law and shall have been announced to the Tax-Bureau of that district 6 weeks before; a similar announcement is necessary from the owners of Factories in which Salt in a pure or impure state is acquired as a by-product.

§.—IV.

Every owner of Salt Works or Factory already in operation, which produces Salt as a by-product, must, within a certain time, to be fixed by the Customs authorities of the district, present to the Head Office of the circuit, in duplicate, a description of and information concerning the manufactory, &c., and its dependencies. Every alteration in the premises as well as in the entrances and exits, as also in the appliances used and general arrangements is to be notified to the authorities before it is put into execution.

A similar duty devolves on any one wishing to establish new or to renew former works where Salt is produced, boiled, or refined, or obtained as a by-product, or on those wishing to start working a Salt, not hitherto traded in.

In building new Works or Refineries &c., the Ordinances of the levying authorities concerning fences &c., are to be observed, as also in erecting dwellings and sheds for the employés.

Where, according to existing regulations, deductions for rent for officials are made, the same must be paid by the Salt mine owner.

§.—V.

Every owner of new or restored salt works is bound to bear the cost of the Customs watching of the same, if the total yearly out put of the Salt does not amount to at least 12,000 *cwt.*

II. CONTROL. §.—VI.

The institutions indicated in §. 3, are subject to the control of the Customs authorities, for the discovery of the made salt liable to duty, as also to prevent any defrauding as regards the trade and business connections; all necessary regulations and papers being obtainable from these authorities.

This control is exercised for each Salt Manufactory by a Salt-Tax-Administration specially appointed or directed. The Manufactories indicated in § 3 paragraph 2 are subject to the control of the nearest Customs' Administration.

§ VII.

According to the instructions indicated in the 6th section, every owner of Salt-works can be obliged by the Customs' authorities,—

1. To take care that the approach to the buildings for boiling and for drying, as well as to the chambers for sorting and breaking up, shall be easily overlooked and be protected by safe locks.

2. So to arrange the Salt Magazine that it shall be satisfactorily secured from forcible or secret with-

drawal of the Salt and to provide the authorities with necessary arrangements for the joint locking of the places.

3. To keep the Salt only in the appointed and announced receptacles, spaces or chambers.

4. To keep exact books showing the Salt made and despatched, and to place these books before the Customs' Officer whenever required.

[The enactments for the carrying out of the Tax are very detailed; the following are some of the points referred to:—Weighing of Salt in sacks; Control and Disposition of Inland Salt; Duties of owners of Salt-works; Withdrawing from the Depots; Allowances for Employees in Salt-works; Removal of Salt within fixed hours only; Monthly Statement of Salt-owners; 3 months' credit on sufficient security; Stores of Salt; Bonded Warehouses; Customs, treatment of Salt springs or Mineral springs, Baths, &c.; Foreign Salt how admitted and treated; Enumeration of objects freed from Salt tax; Products in Manufactories; Salt for Charitable Institutions free.]

EXEMPTIONS FROM SALT DUTY.

The preparation and sale of so-called Baths-Salt which is useless for human food is (under following conditions) free:—

1. The manufacturer must make no change in place or in utensils employed without consent of the Customs' officers.

2. He may keep the stores of this salt in one appointed place only.

3. He must follow his directions concerning approach and exit.

4. The Customs' officers must be admitted any hour of the day, and by night also when the boiling pans are in work.

Farther, rubbish from the salt works containing less than 36 p.c. of salt is quite free of control, and that containing less than 75 p.c. of salt is free, subject to various conditions.

The Customs' officers are to make periodic chemical examinations of the salt that is not being denaturalized and ascertain the exact proportion it contains of kitchen salt.

SALT USED FOR CURING OR PICKLING of herrings and other similar fish and for salting of other things intended for export is free of duty. The salt intended for the preserving of herrings is to be denaturalized with 6 Liter (quarts)* of herring brine to every 50 kilogram (110 lb.) of salt.

Salt may also be allowed free of duty for charitable institutions or in cases of immediate need.

The substances that can be used for DENATURALIZING SALT are the following:—

A. For salt which is to be used for AGRICULTURAL or manufacturing purposes.

(a) For salt destined for the feeding of cattle:

(aa) For that from made salt: $\frac{1}{4}$ per cent of oxide of iron and $\frac{1}{4}$ per cent wormwood powder,

(bb) For that made from rock salt $\frac{3}{8}$ per cent oxide of iron and $\frac{1}{4}$ p.c. wormwood powder.

For the denaturalizing of salt, only such wormwood powder shall be allowed, as has been prepared according to directions and measures appointed by the Customs and has been locked up or taken in charge by them; it must also not be over two years old, dating from the time the raw weed was received.

(b) For so-called cattle-licking rock salt:

(aa) From made salt $\frac{1}{4}$ p.c. oxide of iron and $\frac{1}{4}$ p.c. charcoal powder,

(bb) From rock salt $\frac{3}{8}$ p.c. oxide of iron and $\frac{1}{4}$ p.c. charcoal powder;

(c) For SALT FOR MANURE 1 p.c. of soot.

(d) For salt for manufacturing purposes:

(aa) From made salt: either $\frac{1}{2}$ p.c. train oil or fish oil and $\frac{1}{2}$ p.c. iron oxide, or $\frac{1}{2}$ p.c. train or fish oil and $\frac{1}{2}$ p.c. lamp-black,

(bb) From rock salt either $\frac{1}{2}$ p.c. train oil and $\frac{3}{8}$ p.c. iron oxide, or $\frac{1}{2}$ p.c. train oil and $\frac{3}{8}$ p.c. lamp-black.

B. One of the following denaturalizing agents can be employed for salt destined for manufacturing purposes or for manure: and which has come from inland salt works at which it had once been denaturalized.

The process can be attended to in the godowns of the recipient under Customs supervision. If none of the already named denaturalizing agents is suitable for the purpose intended, one of these following agents can be employed:—

(a) 1 per cent black oxide of manganese; (b) 1 p. c. smalt; (c) $\frac{3}{4}$ p. c. minium or vermilion*; (d) 2 p. c. finely powdered charcoal, peat, black oxide of manganese or coal-dust; (e) $\frac{1}{2}$ p. c.—lamp black; (f) 1 p. c. soot; (g) 5 p. c. palm oil, COCONUT OIL or train oil; (h) 1 p. c. fine dried soap powder, after a previous testing of its purity according to directions already indicated; (i) 4 p. c. iron or copper vitriol; (k) 6 p. c. alum with $\frac{1}{2}$ p. c. pine oil.

For ordered salt, if necessary, some of the following agents may be employed by the Customs' officers:— $\frac{1}{2}$ p. c. mineral oil (peat oil); $\frac{1}{4}$ p. c. red oxide of iron in combination with 0.05 p. c. animal oil; 2 p. c. sulphuric acid (of 66° B. diluted with 3 to 4 parts water), or also only 1 p. c. sulphuric acid of 66° B. with 1 p. c. water, if the salt is for a bona fide manufacturing purpose, and if no other agent can be employed; 2 p. c. strong fuming muriatic acid; 2 p. c. pink salt†; $\frac{1}{2}$ p. c. chloride of tin.

Salt refuse can only be given for agricultural and other purposes free of duty when it has been denaturalized, in one of the ways indicated. Solid pieces like pan-stones must be denaturalized in the same way as rock-salt. Unbroken lumps can only be allowed to individual planters or manufacturers under the following conditions:—

1. The delivery of the same requires the consent of the Customs' authorities. Detailed information of purpose for which used, &c., &c., is required on penalty of forfeiting the privilege, unless every requirement is fulfilled.

2. Those who require the salt for cattle fodder, must state exactly number of cattle kept, &c., and fulfil various other regulations.

CEYLON TEA IN AMERICA: AN INTERVIEW WITH THE LADY DEMONSTRATOR.

"Well," she said, "You may grumble about heat, but I can assure you it was a good deal worse in America than this when I left. My customers were going in pretty largely for *iced* tea then. However I will begin at the beginning, and tell you all I can think of about the tea enterprise as I have to deal with it. I am working under J. H. Parke & Co., the advertisers of the Gold Camel blend. Here you see"—she continued, taking in her hand a tiny two-inch little tin box, daintily got up with a gandy picture of the gold camel on the lid, and a paper of instructions fastened by an elastic strap to the under side "is our sample tin. There is enough tea here for two infusions, and the paper accompanying every box tells exactly how to make it. Well, when I am going to a place to give a demonstration, we first send out a number of circulars saying, I shall be at such and such a store on a certain day. If it is in Philadelphia or anywhere near we send out also our waggon, which

* With regard to minium or vermilion, the German word "mennig" certainly has both these meanings, and yet they are totally different substances. Minium is "red lead," i.e., an oxide of the common metal lead; vermilion is a red sulphide of mercury. Mennig also stands for cinnabar, the chief ore of mercury of which vermilion is a purified form.—M. COCHRAN.

† Pink salt is a double chloride of tin and of ammonium used by dyers.—M. COCHRAN.

* 6 liters=1.32 gallons.

is a very pretty one. It is dark blue with medallions on the sides. Each medallion contains a looking glass, in the centre of which is painted a gold camel and the names of Ceylon and India are also printed. There is an electric bell under this carriage which never stops ringing all the time the waggon moves, and wherever it stops crowds collect to look or to find out where this bell is hidden. The driver wears a scarlet coat, and the horse is a good one, and altogether our waggon attracts notice where it goes. I have it drawn up before the store where my demonstration is going on, which of course brings people about the door. That pleases the store proprietor as well as ourselves, you see. Then if possible I get a window, or part of one in the store, and that I fill up with our advertisements and samples. Next I try always to have my table or counter, or whatever it is that is given me, as near the door as I can, so that I may catch the customers as they pass in and out and set out with flowers, etc., as prettily as possible. Also as you know everybody is equal in America. An assistant is as good as his master, and so I pay far more attention to the people behind the counter than to the proprietors, for it is the men selling other goods who will sell our tea. The first thing I do on entering a store and taking up my stand there, I give every assistant in the place a sample tin. I tell them whenever they are thirsty just to come to the table, and there will always be a cup of tea ready for them. At dinner time there are always probably some who take their meals on the premises, and for them I make a big jug of iced tea, or hot tea just according to the weather, or I give them all an afternoon cup if they prefer that. Of course these little attentions please them, and put them in good humour, and then when customers come they are willing to help the sales if they can, and push our tea a little."

"Now that sounds rather like bribery and corruption to me," I interposed. "However go on."

"It is n't really," she laughed back, "but I won't deny I think it helps us a good deal sometimes. Well, then, the customers come in to buy other goods, and I invite them to come to my table and have a cup of tea before they leave. They are generally quite pleased to do so and I give it to them with sugar and plenty of good cream, or else with a lemon if they prefer it that way, or iced—just as they like. There are bowls of crackers (all biscuits are crackers over there) and I tell them to help themselves; they are welcome to just what they like at the table. Then I tell them while they are drinking it, how Ceylon tea is made, and all the different processes. I describe the plant, and how it is plucked, the withering, drying, firing and all the rest of it; and impress on them how clean the manufacture of Ceylon and Indian tea is compared with that of China or Japan, and how much nicer it is when done by machinery and not hand. They generally ask a lot of questions and are quite interested. Perhaps they will say they have tried it before, but they did not like it; that it tasted like poison, and so on. Then I ask them how they prepared it, and very often I am told that a handful of tea leaves was put in the pan and boiled with the water, or else that the same quantity was dropped into the teapot, and then the pot allowed to stand from two to four hours on the stove.

I assure you," she went on, seeing my look of incredulity, "that is no uncommon way of making tea in America, and then they come and say they don't like it, it is so bitter. You can just fancy what Ceylon tea would taste like heated in that fashion. That is my opportunity. I show them they have gone the wrong way to work altogether, and tell them the right manner of infusion—how much tea to put in, how long to let it stand, and all that, and then I wind up by giving them a sample tin and asking them to try it. There is enough for twice, and I ask them if they do not like the tea the first time to give it a second trial. Generally by the time, they have done so, they like it, and are quite willing to come back to the store and buy. But I forgot to tell you that we have other attractions. Besides the sample tins and our smart waggon with the bell always going we have a phonograph which sings songs and talks up Ceylon tea. Lots of people come to hear that. Then I always keep a supply of pretty cards with pictures about tea making, to give away to the children. Every child who comes in, gets one, and wherever I go I stick up in the window a big toy camel which wags backwards and forwards, and is a famous advertisement for our tea. You see in America we have a great deal of prejudice to overcome. The people are not tea drinkers but coffee drinkers, and you have really to teach them to take tea. Now to show you what I mean by that, I went to Reading once. That is a coal district, and I found the miners took far more tea than any place I had been in. They had never learned to drink coffee, and so there was no obstacle to our sales.

"And what do you charge for your tea over there?"

"Well, we start at 60 cents a pound—that equals about 2s 6d—and go up, but I don't believe there is any more profit, for charges are as you know, higher with us."

PRODUCE AND PLANTING.

THE TREATMENT OF TEA IN LONDON WAREHOUSES.—We published a letter last week on this subject from "An Anxious Planter." It is a matter, we know, that exercises the minds of a great many planters, and one which sooner or later must occupy the attention of the Tea Association. Like other reformers who cannot understand why certain hindrances to the public welfare are permitted to flourish, our correspondent is puzzled to know why the tea industry generally does nothing to mitigate the evils attending the repacking of tea in the London warehouses. He calls attention to the fact that machinery for tea packing is in existence, but for reasons best known to themselves most of the warehouse authorities ignore these machines. It is not in our province to advise experienced men of business how they should carry on their business operations, nor do we wish to infer that in some instances no earnest desire had been made to meet the requirements of the trade and the public in the matter. If in some of the warehouses antiquated methods are preferred, that is the affair of the proprietors of these warehouses. It is our province, however, to give publicity to the legitimate complaints of planters against those who handle their teas, and to ventilate a subject which needs light. There is one point in connection with this repacking question which must not be lost sight of. It is bound up with the duty question. The demand for the removal of duty on tea must come from the consumer say the representatives of the planters, some of whom are not even in favour of abolition. That is a fair way of looking at it,

Therefore it behoves those who handle to see that the re-packing at the warehouses carried out under the best possible conditions, so far as the public are concerned. It would be awkward for the warehouse authorities if the consumers of tea were to couple the economic phase of the question with another reason when they demand, as they may do before long, the abolition of the tea duty. It would be a factor in the situation that would certainly count with the public if all the facts as to the present methods of repacking tea before it finds its way into the hands of the dealers were known, and saw the light in the guise of a new sensation. We have no desire to exaggerate the details, nor do we hold a brief for the consumer in the matter. We merely call the attention of those concerned to the complaints of tea growers on the subject, and accompany the notice with a hint that the matter well deserves attention before it enters, as it may do, on an acute and unpleasant stage.—*H. and C. Mail*, Aug. 6.

THE CONSOLIDATED TEA AND LANDS COMPANY, LIMITED.

The first ordinary general meeting of the shareholders of this Company was held on 30th ultimo, in the Accountants' Hall, Glasgow, Sir John Muir, Bart, presiding.

PROFITS.

The Chairman said:—We have much pleasure in submitting to you the accounts of the past season, which show a credit balance, exclusive of profits made in sales of land, of £112,228, or £18,252 more than the average profits in the prospectus. Over and above this profit made on tea-trading we also show a profit made on the sale of the Travancore property of £63,162 4s or altogether a profit for the year of £175,380 19d. This enables us to pay dividends at the rate of 5 per cent. and 7 per cent. on the preference shares of both classes, to pay the interest due to the vendors, to propose a dividend of 10 per cent. on the ordinary shares, to pass £65,000 to a reserve fund, and to carry forward to next year £14,236 5s 4d. These figures speak for themselves, and I need not detain you further on the subject of the accounts. During the year under review we have added 4,827½ acres to the area of cultivation, and we are engaged in opening up a further area of 4,337 acres during the current year. You will observe that our crop for 1896 show a substantial increase over the previous year, and so far as we can gather from the advices from the estates, this quantity will be again increased in the current year. The new extensions consist not only of tea, but of coffee, cocoa, coconuts, and india rubber. We wish to encourage the growth of these products other than tea as much as possible, so as not to have all our eggs in one basket. In addition to this, the tea extensions we are making are practically all on lands capable of producing high quality tea, such as Upper Assam and the Travancore Hills. We are sure this is a wise policy. We are not disposed at present to extend our area of medium tea, as we think it possible there may be in the future an over-supply of this class of tea, whilst we think the demand for the higher qualities of tea is likely to increase.

OVER-PRODUCTION.

The Chairman of the Doonars Company has recently pointed out a possible danger to the tea industry in over-production, and this is, in our opinion, a real danger so far as concerns medium and common teas. On the other hand, everything points to the maintenance of prices for really good quality teas, and these are the teas we intend specially to cultivate and to extend. Of course, increased production in medium teas may be met as heretofore by increased consumption and new outlets. China tea is now, however, almost entirely displaced in Great Britain, and consequently, unless energy is shown in opening up new markets, a glut of medium teas in the home market may arise.

The subject of possible over-supply of medium teas is occupying our attention, and the remedies we are

encouraging are: 1. Economy in working; 2. Increased production of high quality tea; 3. The opening up of new markets. In regard to the latter, I am pleased to tell you that this company has sold in the United States and Canada during the past year more than two million pounds weight. It may interest you if I give our figures of sales in previous years in these countries on account of the North and South Sylhet Tea Companies, Limited, whose properties, including their American business, were acquired by this company:—1893, 707,200 lb; 1894, 1,288,147 lb; 1885, 1,591,324 lb; 1896, 2,099,784 lb; six months—1897, 1,665,044 lb. I think you will admit that this shows gratifying progress.

PUSHING TEA IN RUSSIA.

In addition to this I am glad to tell you we have recently made satisfactory arrangements for the pushing of British-grown teas on a large scale in Russia, and I hope at future meetings to report to you encouraging progress in this direction. These statements will, I think, satisfy you that the Consolidated Company is doing its duty in increasing in every legitimate way the opening up of new markets.

THE EARTHQUAKE.

As you are aware, a severe shock of earthquake passed over the tea districts last month, and fears were entertained, from the first account received, that the crop prospects for the year would be seriously affected by the damage done; but I am glad to inform you that the picking of crop has not been stopped for a single day on any of the company's estates, and energetic steps have been taken by the management to repair the damage done to bungalows, houses, and other buildings, so that we are able to report to you that the company has sustained no loss which cannot promptly be replaced, and, as already stated, we have suffered no loss of crop.

AMALGAMATION.

Regarding the sale of the North Travancore lands you are aware the company owned a large tract of very valuable high-country land in this district—more than it would have been possible for us to utilise profitably by ourselves. As foreshadowed in the prospectus, it was at first our intention to sell some of this land, or to form subsidiary companies for working part of it. After careful inquiry, however, we came to the conclusion that the introduction of outside elements would be detrimental to the company's interests. The only alternatives, therefore, were either to create new capital and work the whole of it ourselves, or to combine with others for that purpose. We felt, under all the circumstances, the latter would be the wiser course, and we accordingly came to an understanding with the Amalgamated Tea Estates Company (in which company most of the Consolidated Company's shareholders are interested) to work the whole of the Travancore lands on joint and equal account. To carry this out effectively a new company was formed, called the Kanan Devan Hills Produce Company, Limited, in which the two companies are the shareholders. The property was taken over from this company by the new company at a valuation arrived at by two experienced experts, Mr. W. Milne and Mr. L. Davidson, and the transaction showed a profit to the Consolidated Company of £63,152 4s. I have no doubt this powerful combination will lead to better results than if we had endeavoured to work single-handed. We have also entered into an arrangement with the East India and Ceylon Tea Company, Limited, to amalgamate the two companies' interests in the Bambarabotta district of Ceylon. This will be done through the formation of the Hopewell Tea Company, Limited, in which this company will have a two-third interest, and the East India and Ceylon Tea Company, Limited, one-third. This amalgamation will lead to more profitable working than if the two companies remained as active competitors in the same district. The properties of both companies will be taken over at a valuation to be arrived at on September 15th, and the result will appear in the current year's accounts. I am satisfied we should in every way encourage

combinations such as these, as they tend to keep down rates and reduce the cost of management. I am glad to have the opportunity of stating that the companies' superintendents, managers, and assistants are working well, and have as a rule given us satisfaction. I do not think I need detain you any longer.

I am happy to be able to give you so satisfactory an account of our first year's working, and, whilst we must expect ups and downs sometimes, I trust when we next meet I shall have an equally satisfactory report to make. I have pleasure in proposing the following resolution:—"That the balance-sheet and profit and loss account for the year ending November 30th, 1896, with the auditors' certificate and the directors' report thereon, be and the same are hereby received, approved, and adopted; that the dividend at the rate of 5 per cent., less income tax, paid to November 30th, 1896, on the first preference shares of the company be and the same is hereby confirmed; that a dividend at the rate of 7 per cent., less income tax, to November 30th, 1896, on the second preference shares of the company be now sanctioned and declared; and that a dividend of ten per cent., less income-tax payable August 14th next, be now sanctioned and declared out of the balance of the profits of the year on the amount paid upon the ordinary shares of the company, £65,000 placed to credit of a reserve fund, and the balance of £14,236 5s 4d carried forward to next year.

Mr. BUCHANAN seconded the resolution, and Mr. CARRITT, in the course of a few remarks expressed approval of the steps which the directors were taking in the way of increasing the growth of fine teas, selling the Travancore property, and extending the trade to Russia.

The motion was unanimously adopted. The auditors were reappointed, and after a vote of thanks had been passed to the chairman, the proceedings terminated.—*Glasgow Paper.*

INDIAN PATENTS.

Aug. 21.

Applications in respect of the undermentioned inventions have been filed, under the provisions of the Inventions and Designs Act of 1888, in the office of the Secretary appointed under that Act, during the week ending 7th August 1897:—

Improvements in Apparatus for the Drying or other Treatment of Tea Leaf.—No. 306 of 1897.—Samuel Cleland Davidson, merchant, of Sirocco Engineering Works, Belfast, for improvements in apparatus for the drying or other treatment of tea leaf, tobacco leaf, grain, malt, fruits and other substances.

Improvements in the Method of and Apparatus for Extracting Oil from Seeds.—No. 448 of 1896.—William Robert Harrison, consulting engineer, and Edwin Stephenson, oil refiner, both of Hull in the county of York, for improvements in the method of and apparatus for extracting oil from seeds or other oleaginous substances. (Specification filed 2nd Aug. 1897.)

Improvements in Tea-Rolling Machines.—No. 333 of 1892.—John Brown, engineer, of London, for improvements in tea-rolling machines. (From 7th Aug. 1897 to 7th Aug. 1898.—*Indian and Eastern Engineer.*)

THE HISTORY OF THE SWEET PEA,— SUPPOSED NATIVITY IN CEYLON.

In the *Florist's Exchange* for July 17, Mr. S. B. Dicks contributes an article on this subject, with illustrations copied from some of the older books. Mr. Dicks traces the sweet pea to John Banhin's *Historia*, 1650. The plant itself is a native of Sicily, but one form of it was considered to have come from Ceylon, and was accordingly called by Burmann, *Lathyrus-zeylanicus*. The word "nobis," which has misled Mr. Dicks, of course applies to Burmann himself! How the

mistake arose of considering the Sweet Pea as a native of Ceylon, we cannot tell. For those with leisure, it would, no doubt, form an interesting subject of enquiry. It is certain that neither Baker, in Hooker's *Flora of British India*, nor Trimen in *Handbook to the Flora of Ceylon*, admits the plant as a native of the island, though it is likely to have been taken there.—*Gardner's Chronicle*, Aug. 7.

VALUE OF TEAK.

In an article in *Timber* (London) on the value of teak for structural and mechanical purposes, the claim is put forth that such wood is really the most durable timber known and of especial importance to shipbuilders, being very hard, very light, easily worked, and, though porous, strong and lasting. It is soon seasoned, shrinks but little, and on account of its oily nature does not injure iron. In southeastern Asia it is not only considered the best material for ship construction, but for house carpentry and other work where strength and other lasting qualities are required. It is rarely attacked by ants of the white-species, and its rare durability renders it specially valuable in a climate like that of India, where the elements causing decay are so numerous and powerful, where dampness brings on rapid decomposition, and where the white ant devours without scruple. In the operation of cutting this wood is frequently girdled one or two years before it is felled.

CITRONELLA OIL.

Mr. J. C. Umney communicated, in a skilful abstract of his paper at the 34th annual meeting of the British Pharmaceutical Conference held at Glasgow from August 9th to 12th, the interesting fact that the native distilled oil of citronella has not so high a specific gravity as that distilled by two English firms in the East:—

He and Mr. R. S. Swinton have investigated the reasons for the difference, and find that the native oil contains a large percentage of a heavy and high-boiling sesquiterpene, which reduces considerably the odour value. The "English" oil is of finer aroma on this account, and Mr. Umney explained that the low specific gravity of the native oil is not an indication of impurity. The difference referred to is probably due to the use of steam-heat by the English firms in distilling, and of fire-heat by the natives; at any rate lavender oil distilled by steam is found to be of much finer odour than the oil distilled by fire-heat as done at Mitcham. Mr. Umney also mentioned that Sir Walter Gilbey is experimenting in the cultivation of lavender at Elsenham, in Essex.—*Chemist and Druggist.*

THE SCHOOL OF FORESTRY, CEYLON.

This school started work on the 15th of April with six students (a limited number), three of whom were drafted from the Forest Department, and the remaining three selected from the students of the School of Agriculture after competitive examination. The following is a list of the subjects taught, with the names of the teachers annexed:—

Forestry ..	Mr. Broun, Conservator of Forests.
Mathematics..	Mr. Walter Parys,
Forest Law ..	Mr. F. M. de Saram, Advocate.
Surveying ..	Mr. Dyson Blair.
Botany ..	Mr. Drieberg, Superintendent, School of Agriculture.

The course of trainings at present arranged covers one year. During the latter part of the year the students were taken on tour by the Conservator of

Forests himself. The tour occupied about six weeks, during which period many of the forests of the North-Western and Central Provinces that lie on the route between Kurunegala, Dambulla, and Matale were traversed, while visits were also paid to the Galboda, Nanu-oya, and Nuwara Eliya plantations. The six students who will be the first trained in the Forestry School are Messrs. Jansz, Jayman, and Galagoda of the Forest Department, and Messrs. Fernado, Mendis, and Ratnayak from the School of Agriculture.—*Report of Mr. C. Drieberg, Superintendent of School of Agriculture.*

HOW TO DEAL WITH LOCUSTS.

A LOCUST-DESTROYING FUNGUS.

In connection with the question of remedies and devices for the destruction of locusts, Dr. Edington of the Bacteriological Institute, Graham's Town, has prepared a fungus, experiments with which have been made by Messrs. Acutt and Crew, farmers in the Buluwayo district, which have proved highly satisfactory. Samples of the toxic preparation may be obtained gratis through the various Civil Commissioners in Cape Colony, with instructions as to its use. Of its efficacy, Mr. E. Roos-Townsend, Civil Commissioner at Buluwayo, in asking for a fresh supply, says:—

"I have distributed the tubes as widely as possible, and the universal opinion is that the results are most satisfactory, and there is a large demand for a further supply. The protracted drought has somewhat handicapped the experiment; nevertheless, it has been so successful that one can fairly assume that, given favourable conditions, i.e., damp weather, the results would be most satisfactory. Hitherto experiments have been confined to the 'voet-ganger' stage of the pest. These are more easily dealt with, and the results can be more closely watched. Unfortunately we have not had sufficient of the fungus to make any perceptible impression on the myriads of the insects which have been hatching throughout the country. Had we sufficient toxin, I think we should be able to make use of it to a large extent in settling many of the native troubles, for those who have seen its satisfactory results regard the power of the white man with superstitious awe, and look to us to root out this pest which has so persistently taken their crops ever since the white man came into their country in 1890.—*Home paper.*

THE AMSTERDAM CINCHONA MARKET.

Our Amsterdam correspondent writes, under date of August 4, that the auctions to be held on August 26th will consist of 5,448 bags, and 854 cases Java bark. The stock in first hands, including the above quantity, consists of 2,163 cases Government, and 6,739 cases private, bark. The shipments from Java during June have been declared as follows (in Amsterdam lbs.):—

	1897	1896	1895	1894	1893
July	900,000	1,774,000	548,000	953,000	680,000
Jan.-July	4,308,000	5,050,000	4,316,000	4,701,000	4,740,000

It will be seen that the shipments are smaller than at the corresponding period of last year, whilst it must not be overlooked that in the meantime the stocks in Amsterdam have greatly diminished. The feeling is firm, and a good demand is looked for at the coming sales.—*Chemist and Druggist.*

INDIAN PATENTS.

Applications in respect of the undermentioned inventions have been filed, under the provisions of the Inventions and Designs Act of 1888, in the office of the Secretary appointed under that Act, during the week ending 14th August 1897:—

Rotary sifter for tea or other material.—No. 317 of 1897.—E. Pauling, engineer, of Khobong tea estate, Jalup P. O., Dibrugarh, Assam for a rotary sifter for tea or other material.

The fees prescribed in Schedule 4 of Act V of 1888 have been paid for the continuance of exclusive privilege in respect of the undermentioned inventions for the periods shown against each:—

Cleaning and polishing rice.—No. 17 of 1892. Christian Ludwig Melosch, millowner and dealer in rice, of Chetla hat, Alipore, Twenty-four Pergunnahs, Bengal, for cleaning and polishing rice. (From 16th August 1897 to 16th August 1898.)—*Indian and Eastern Engineer, Aug. 28.*

PERAK.

EXPORT PRICES OF COFFEE AND GUTTA

FOR JULY.

Liberian Coffee, \$22 to \$23 per pikul.
 India Rubber, First quality, \$145 to \$155 per pikul.
 " Second quality, \$105 to \$115 per pikul.
 Guita Percha, First quality, \$300 to \$325 per pikul.
 " Second quality, \$280 to \$290 per pikul.
Perak Government Gazette.

PLANTING NOTES.

RUBBER FROM THE AUSTRALIAN TROPICS.—The enormous increase in the price of rubber within the last ten years has led to the cultivation of the plant in many new countries. Certain British chemists are now visiting the rubber-producing countries in South America with a view to improve the quality of the product, and in Queensland, New South Wales, and South Australia inquiries are being made as to the possibilities of the industry. Mr. Maurice Holtze, then director of the Port Darwin Botanic Garden, in 1888 advocated the planting out of Ceara rubber and Para rubber trees in the Government forests. At present it is said that a wealthy London firm are about to start rubber-planting on a very large scale in Bathurst Island, to the north of Port Darwin.—*Chemist and Druggist Aug. 14.*

KOLA NUT CULTIVATION.—A planter asks for information in respect of this new product, and we have referred him to the *T.A.* volumes and our "planting review" for the best summary of what has been done locally. We believe there is a good demand: the latest quotation is about 3d a lb. Here is a further reference to Kola or Cola nuts:—

C. acuminata grows about forty feet high, and bears pale yellow flowers spotted with purple; its leaves are about six or eight inches long, and pointed at both ends. Under the name of Cola, or Kolla, or Gora nuts, the seeds of this tree are extensively used as a sort of condiment by the natives of western and central tropical Africa; and likewise by the negroes in the West Indies and Brazil, by whom the tree has been introduced into those countries. In Western Africa the trees grow mostly in the vicinity of the coast, and an extensive trade is carried on in Cola nuts with the natives of the interior; the practice of eating Cola extending as far as Fezzan and Tripoli. A small piece of one of these seeds is chewed before each meal as a promoter of digestion; it is also supposed to prove the flavour of anything eaten after it, and even to render half putrid water drinkable. There are several varieties of Cola nuts; the common kind has an astringent taste. [The Bitter Cola of Fernando Po is the produce of some guttiferous tree, as yet not identified.] Powdered Cola is applied to cuts.

COFFEE AND PEPPER EXPORTS

FROM SOUTHERN INDIA:

GREAT FALLING-OFF IN COFFEE AND
INCREASE IN PEPPER;"LADYBIRD" BEETLES WANTED TO SAVE
COFFEE;WHY NOT CULTIVATE PEPPER FREELY
IN CEYLON?

We are once again indebted to our old friend, Mr. Ralph Tatham (agent on the West Coast of India for Messrs. Arbuthnot & Co.) for the Annual Statement of Coffee and Pepper Exports from Southern India. His letter and full detailed table will be found as a Supplement on opposite page, and are worthy of the attention of all who take an interest in our old staple and in the second product—Pepper—which was once a leading export from Ceylon, and which ought to be a good deal more cultivated than it is in our Western Province and especially in the Kegalla district where "pepper" reigned supreme in the times of the Dutch and the early part of the present century. Planters, even in the Kelani Valley, are on the lookout for another "string to their bow" and have been testing Liberian coffee, &c.,—why not then try pepper? What good reason can be given why Southern India should export in one year as much as 222,383 cwt. of pepper valued at nearly four million of rupees; while Ceylon last year exported only a miserable 374 cwt. worth ten thousand rupees? The Dutch had an export rising from 4,000 to 5,000 cwt., chiefly picked in the Kegalla and Hanwella districts, and Governor Van Imhoff in 1740 considered that pepper was a far more important product for cultivation in Ceylon than either cardamoms or coffee, and that the natives should be induced to greatly extend the industry in this spice which might in course of time be made to rival its far-famed sister spice, Ceylon cinnamon. Now that the Governor is visiting the Kegalla district and that both His Excellency and the planters want to ensure a steady and increasing traffic for the new Kelani railway, we trust attention will be turned to this time-honored and very profitable product so long peculiar to the said Kegalla district. The case is one where the Director of the Botanic Gardens might well be asked, in conjunction with the Assistant Agent of the district and the local Planters' Association, to inquire how best the culture of pepper can be revived in native gardens, and introduced into European plantations in Kegalla and Ratnapura districts as also in adjacent portions of the Western Province.

Turning to coffee, Mr. Tatham has but a poor account to furnish and we much fear it is "the beginning of the end" for this staple in Mysore and Coorg as it was in the "eighties" in Ceylon. The conditions described at the recent meeting of the United Planters' Association of Southern India, exactly coincide with the experience of Uva—our driest and richest district in this island—a few years back. Until then, coffee in Uva had kept up against leaf disease; but when "green bug" appeared the planters found they had a far more terrible enemy to contend with and gradually nearly every one of them had to give up the struggle. The only chance we can see for coffee in Mysore and Coorg lies in the introduction of the "lady-bird" beetles to eat off the pernicious bug as they, apparently,

have done, from the coffee of the Hawaiian islands. Our latest information on the subject from Mr. E. E. Green—to whom we referred some papers—is encouraging. We quote as follows from Mr. Green's letter:—

The correspondence between the Government of Madras and the Commissioner of Agriculture to the Hawaiian Government bears high testimony to the value of Mr. Koebele's work in the introduction of "Lady bird" beetles and other beneficial insects. I think you have already published the Commissioner's letter in reply to the enquiries of the Madras Government. He states that Mr. Koebele's services would be unavailable for at least two or three years to come. (They appreciate the value of his work too much to part with him in a hurry). But the Commissioner is making enquiries in the United States for other trained entomologists who might be willing to undertake the work. If anything is to be done—it should be done quickly—or there will be little coffee left to benefit. I have by this last mail received a letter from Mr. Alexander Craw, quarantine officer and entomologist to the State Board of Horticulture, California. He writes:—"Our new lady-birds are doing splendid work, and especially *Rhizophagus ventralis* on *Lecaniums*, that there was so much adverse criticism about when we first distributed them. Two weeks ago I sent Dr. L. O. Howard two good sized boxes of *Vedalia Cardinalis* and *Novius Kabei* to send to Egypt."

We commend this important information to the attention of Mr. Tatham, his principals Messrs. Arbuthnot & Co., and to all others interested in the maintenance of coffee in Southern India, and also to the few proprietors who have fields of the old staple still remaining in Ceylon. It will be a great pity if the opportunity is lost of giving a fair trial to the lady-bird beetle against the "green bug" before any coffee left both here and in Mysore and Coorg, is weakened beyond recovery.

"HOW TO ECONOMISE LABOUR."—A proprietary planter thus expresses his opinion in reference to the series of letters now appearing in our columns:—"I think this series of questions will prove most interesting and useful. There is no doubt that some stirring up of the mental soil is wanted in these directions. There has, no doubt, been a tendency to keep too long in a groove, especially with regard to weeding. We have come to look upon the existing state of things in the same way as formerly they accepted the flatness and fixity of the earth. Did anything practical ever come of that single-rail railway in Ireland? Something of that nature might be a saving in cost and suitable in Ceylon. If it could be laid down cheaply enough, some modification of the 'Switchback' might be practical. But Government ought to do more in the matter of providing cart roads to stations. By estate path I am under four miles from the station; by cart road 8½, two and a half of which I have to carry my tea and everything else on coolies' heads. For the last few months, I have been unable to take my horse to the station on account of the bridges. [Now there is a very good trace for a cart road to the station, which would join the estates from the Dimbula Gap by a loop road. Sackville was very keen on this being carried through, but got no support, and so it remains.] Cuscut grass I do not know, but if it neither seeds nor spreads it would act very beneficially in preventing loss of soil if planted above drains. My coolies are allowed all the garden room in a reasonable way they wish, but what they do not like is transport."

Correspondence.

To the Editor

SALT IN AGRICULTURE.

Kandy, 25th October 1855.

To the Secretary of the Planters' Association, Kandy.

Sir,—My attention for sometime has been given to the subject of employing *common salt* as an element in preparing fertilizers for coffee lands—and this subject I learn, is at present under consideration of Government, with the view chiefly of ascertaining whether some modification of the existing revenue regulations respecting salt might not be effected for the purpose of rendering this element more available for use on estates for manure, and for food for stock. And as the value of common salt as a fertilizer either by itself, or when brought largely into use in combination with other materials, has by some scientific men in the island, been questioned in its applicability to coffee in particular and generally to intertropical culture, I have been led to bring the subject, through you and the press, to the notice of the planting community in the hope that this course may elicit opinions and lead to experiments which may throw valuable light upon a question of some interest to us all.

Professor James F. W. Johnston, whose eminence as an Agricultural Chemist none will question, whose writings upon Agricultural Chemistry have been translated into every language of Europe, and some of whose works on the modern subject have been adopted as class-books, in many of the public schools, abroad and at home, is much in favor of the use of salt as a fertilizer. He has written a work on the use of salt in agriculture, which I regret not having, but upon referring to his other works I find much said upon the subject which I shall take the liberty of embodying in this communication making comments of my own as they occur, in relation to considerations of a local character.

Johnston says in his "History of Fertilizers" second edition:—"It would be difficult to name any other substance in the catalogue of fertilizers whose powers have been so often disputed as common salt." But he adds, "It has been generally employed with little scientific accuracy and in far too loose a manner for reliance to be placed upon reports upon its use. It is an agent which though employed in various agricultural operations from the earliest periods, has had to encounter many prejudices, obstacles and even prohibitions. Since the repeal of the duties in England the consumption by Farmers has rapidly increased. The examinations which have been carefully made of salt in the last ten years have demonstrated many important truths, dispelled much ignorant and absurd reasoning, and cleared the path for future investigators."

"Common salt is composed, according to Dr. Marcet, of *Chlorine* (a gas of a greenish colour, and unpleasant taste, and a suffocating odour, which combining with other substances forms *chlorides*) 59½ parts—and *sodium*, the metallic base of soda 40½ parts. Its fertilizing properties when applied to land are—

1st.—It promotes decomposition of animal and vegetable substances in all cultivated soils.

2nd.—It destroys vermin, kills weeds, &c., which are thus converted into manure.

3rd.—It is a direct constituent or food of some plants.

4th.—It acts on vegetable substances as a stimulant.—Dr. Priestly proved this by various interesting experiments shewing that while an overdose of salt killed plants, a limited application in water kept them alive longer than those treated with water alone. A solution of chlorine in water will make certain seeds vegetate which would otherwise rot in the earth.

5th.—Salt preserves vegetables from injury by sudden transitions in the temperature of the atmosphere.

6th (and most important).—Salt renders earth more capable of absorbing the moisture of the atmosphere, a property of the first importance, since those soils which absorb the greatest proportion of moisture, are always the most valuable to the cultivator. "It affords" (said Davy, Agric. Chem. p. 184) "one method of judging of the productiveness of land." The absorbent powers of common salt applied to land, are shewn by a table of experiments to be greater than those of six other well known manures.

The coffee plant, like the gluten cereals, in its development and productive powers is barely affected by the nitrates, whether derived from the soil or from the atmosphere. Johnston says "salt rarely causes the wheat (a gluten cereal) to grow larger or taller, but it fills the ear better, and brings the weak plants forward. On Mr. Sinclair's authority, salt appears to lessen the production of straw and increase the weight of grain.

Soil without any manure for four years gave 13 bushels weight per acre.

Ditto with 5 bushels of salt per acre, and no other manure gave 26 bushels.

Soil with 45 tons pit manure gave 49 bushels wheat per acre.

Ditto with 44 bushels salt added gave 75 bushels per acre.

Soil with 5½ bushels salt and 5½ bushels oil cake applied as manure gave 6½ bushels per acre.

Soil without any manure produced 30 bushels of barley per acre.

Ditto dressed with 16 bushels of salt per acre gave 51 bushels of barley per acre.

Sir Thomas Acland—August 1826—considered salt a good manure for light soils, but not calculated for clay or heavy lands.

Mr. Collins Devonshire, whose farm is almost entirely a light black sand, writes, "I have found salt answer my most sanguine expectations, both as to the increased quantity and improved quality of the crops. My barley and oats which used to yield only 15 to 20 bushels per acre, now yield 40 to 45. In every field salted, I have found the grass very much superior to any produced before the use of salt."

For potatoes (a starch plant) a great Totham in Essex, with simple soil, the produce per acre was 120 bushels. Soil with 20 bushels of salt 192 bushels—with 20 loads of manure, 219 bushels. Ditto with 20 bushels of salt added, 234 bushels. At Hollenden house, Kent—soil three-fourths sand, without any manure gave 157 bushels, with salt 199 bushels. With 8 bushels salt, and 30 bushels soot 240 bushels. This Agriculturist adds "of ten different manures, salt, a manure hitherto of an ambiguous character, is, (one only excepted) superior to them all. The effect of the mixture of the salt and soot is remarkable."

Salt may be employed in gardens as a fertilizer with decided advantage,—in the case of some vegetables improving the crop by fifty per cent. A very small quantity of salt added to the water in which cauliflowers are placed adds considerably to their duration—it is a common custom with the importers of Exotic plants to dip cuttings into salt water. Before the adoption of this plan they almost invariably perished on the passage. An eminent florist Mr. Hogg of Paddington, says, "from the few experiments I have tried with salt as a Garden manure I am fully prepared to bear testimony to its usefulness."

Salt acts as a destroyer of grubs and like vermin. Mr. Burk in Hertfordshire used it on his land for the purpose of destroying worms and slugs, with which it was very much infested, and says in some fields this was the means of preventing the total destruction of the crop. There is other numerous testimony to the same effect. It is customary in most counties of England to apply salt and water as a steep to prevent the ravages of disease in wheat called *smut*. Recent experiments have suggested that it may even be of use when employed in large

quantities as a preventative of *mildew*. The experiments of the Rev. E. Cartwright strongly evidence that when salt and water are sprinkled with a brush upon diseased plants it acts as a complete cure. It appeared in the course of some enquiries made by the Board of Agriculture that a Cornish farmer, Mr. Sickler, and the Rev. R. Hoblin, were accustomed to employ refuse salt as a manure and that their crops were never affected with *Rust* or blight.

Salt is also a complete preventative of the ravages of the weevil, and other insect vermin, which attack the corn in granaries. It has been successfully employed in the proportion of a pint of salt to a barrel of wheat. An American corn merchant states that wheat placed in old salt barrels is never attacked by those destructive vermin. Query—might not salt, sprinkled in water upon the trees or existing as an element of food for the roots of the coffee plants, be an effective agent in removal of the aphides, known as the black and white bugs of Ceylon.

Salt has of late years been used in Great Britain at the rate of from 20 to 40 bushels per acre to kill weeds, if the cultivator can collect weeds, parings of turf, cleanings of dams, roads, &c., and spread on the surface of the heap half a bushel of salt to every ton of the collection, he will find every weed killed, and dissolved away in the course of a few weeks. Query.—Would not salt in the above proportion sprinkled upon the litter on the patanas, spread for cattle bedding, operate a more rapid dissolution and preparation of made compost, than would take place without it?

The light soils appear decidedly the most benefited by an application of salt as a fertilizer. For such soils it is found that salt is much more valuable if mixed with lime and laid in a damp place, as a cellar or shed, some weeks before it is spread on the land, as it, by this means, suffers a partial decomposition and the mass of salt and lime becomes partially mixed with a considerable proportion of chloride of lime and soda, both deliquescent and consequently moisture absorbing salts. It is by such a process in fact that common salt is decomposed in France by the Soda manufacturers. On heavy lands the use of salt has never been so strikingly advantageous as upon the lighter, more thirsty, upland soils, and that may be accounted for by the more absorbent powers of common salt on such lands being less needed. The mixture of salt with other well known fertilizers is a question well worthy of the agriculturist's attention. And chiefly with reference to the decomposition which occurs when it is mixed with lime, or when used as a compost with weeds, mud, vegetable refuse, &c., and the extraordinary effects when mixed with *soot* as a manure for wheat.

The use of salt as a manure since the repeal of the duties in England has been considerable: its high price stood chiefly in the way of its use from the time of William III. In 1804 experiments were entered upon which proved that out of 25 manures, salt and lime were found superior to 19 others (com. Board. Agri. Vol. 4) and in 1816 Mr. J. Manley of Cheshire before a committee of the House of Commons stated that he increased his produce 5 bushels per acre by dressing with salted marl.

A mixture of salt and lime was recommended so long ago as the 16th century. The celebrated German Chemist Glauber, described at some length the mode of preparing it, and characterized the compound of soda and muriate of lime produced, as "most fit for dunging lands, and to be used instead of the common beasts' dung." Christopher Packe, in 1688 publishing Glauber's works, enforces the value of this fertilizing compound with much earnestness, and describes it in his preface as the cheapest of all mixtures for the enriching of poor and barren land."

From the Farmer's guide, published in 1768 we read "now I come to treat of the mother of all manures, viz. Salt.—Take 6 bushels salt, 6 bushels lime, 6 of dry ashes, and mix them all together.

This is sufficient for an English acre." In Sinclair's Husbandry of Scotland we are told to slake 32 bushels of lime with boiled salt water, made into a compost with 40 loads of earth it will be sufficient for an acre. The component parts of the mixture will be muriate and sulphate of lime, mineral alkali in an uncombined state, and also muriat and carbonate of soda.

The mixture of salt and lime is recommended in the proportion of 2 of lime to one of salt, the mixture to remain incorporated in a shady place or covered with soil, for two or three months, by this process a gradual decomposition takes place—muriate of lime, and soda, are formed—and the whole mass speedily becomes encrusted with alkali. There is another advantage from this process besides the formation of soda. The muriate of lime is one of the most deliquescent, or moisture absorbing substances with which we are acquainted, and in consequence, whenever it exists in a soil, the warmth and force of the sun has much less injurious influence on it than it otherwise would have.

Mr. Kimberly, a practical farmer of 500 acres at Trotsworth near Egham, says "salt improves the condition of all kinds of stock and increase the durability and value of their manure. With reference to the applicability of marine salt for my liquid manure I have no hesitation in stating that it is one of the most valuable ingredients of its basis, and a material which every farmer should have in his possession as one of the most important means of supplying himself with manure at all times—and therefore any measure that will cheapen, and facilitate the introduction of salt into the agricultural districts, will cause an incalculable benefit upon the landed interest. I consider salt one of the most essential of our artificial manures."

Salt has never been employed with other substances so extensively as it might, with soot (the chief constituent of which is sulphate of ammonia, a deliquescent salt) it produces the most remarkable effects. Mr. G. Sinclair found that when unmanured soil gave 23 tons of carrots per acre, the same soil fertilized with a mixture of only 6½ bushels of salt and 6½ of soot, yielded 40 tons per acre. Mr. Belfield describes the mixture as equally beneficial for wheat (*a gluten cereal*) and Mr. Cartwright found that when the soil without any addition yielded per acre 175 bushels potatoes (a starch plant—*Rice* being a starch cereal) that dressing the same land with a mixture of 30 bushels of soot and 8 bushels of salt the produce per acre was 200 (Com. Board Agri. vol. IV.)

Salt may be easily separable from lime if the mixture be subjected to suitable process before decomposition takes place, but not so after new chemical combinations have taken place in both materials.—Mixing salt with coal tar would probably thoroughly pollute the salt so as to render it utterly unfit for use as an ingredient in animal food, while coal tar, either alone, or in combination with salt, is rich in fertilizing bases, when these have been rendered soluble by decomposition. For all vegetable productions which are affected favorably by the nitrates, coal tar is suitable as a manure. It is composed entirely of substances which enter into the composition of all plants, is gradually decomposed in the soil and is powerful in its effects from containing a considerable proportion of the carbonate acetate of ammonia.

Coal tar and lime, however, ought not to be mixed in view of application as a manure to land because the tar uniting with the lime forms into a hard cement in which state, even if with considerable labour it were broken into small particles, it can be of but little service to any soil.

An overdose of salt to land kills vegetation. If a soil contain naturally sufficient chlorine and soda, in any state of combination, not only would salt be unnecessary as an ingredient of manure, but it might be deleterious. It is said that the soil of the interior of Ceylon is rich in the muriates, but this is not borne out by the straitened development and small

productiveness of such marine plants as the coconut tree whenever grown far from the sea coast. The addition of a handful of salt to the roots of the coconut trees in the Kancian Province is always attended with marked beneficial results. There are however few points more easily or closely ascertainable by an analyzer of soils, and it would be interesting and valuable to have the result or analysis of soils at different altitudes and distances from the sea. If the soil of the interior be rich or moderately well provided, with muriates, the alkalies could be furnished in some other form than in that of salt, which in that case might be injurious.

With reference to the action of salt when introduced into the sap of plants, we must consider the theory of chlorides, which is this. Common salt (and other chlorides) is frequently found in the sap of plants, supposed to enter into the roots dissolved into water, but without having undergone any previous decomposition. Sprengel and Meyen state that when plants grow in soil containing much common salt, they have been observed to evolve chlorine gas from their leaves as some plants give off ammonia and other emit from their leaves pure nitrogen (Danbeny). The evolution of chlorine implies the previous decomposition of the chlorides which have been absorbed from the soil. The green leaves under the influence of the sun, have the power of decomposing common salt, and of giving off their chlorine into the surrounding air. When chlorides have been introduced into the sap therefore by the roots, the plant appropriates so much of the chlorine they contain as is necessary for the supply of its natural wants, and evolves the rest. When common salt is thus decomposed, *Soda* remains behind in the sap, and this is either worked up into the substance of the plant or performs one or other of those indirect functions of alkalies, for the performance of which these are so indispensable in the economy of nature.

In the soil itself, in which organic matter of animal and vegetable origin is present, common salt is fitted to promote certain chemical changes, such as the production of alkaline nitrates, and probably silicates, by which the growth of various kinds of plants is in a greater or less degree invigorated. In the soil also from their tendency to deliquesce, or run into fluid, all these chlorides attract water from the air, and thus help to keep the soil in a state of moisture.

In the ash of the coffee bean there is no less than 70 per cent of alkaline matter, and 122 per cent of chlorine. Soda often takes the place of potash, if not altogether at least to a very large extent. We do not know all the functions these alkalies perform in the living vegetable. They render soluble silicide, &c. and are connected with the preparation and absorption of food from the soil and with the changes which the organic substances undergo in the circulation of the plant. Soda and potash are equally fitted to perform these functions, as has been confirmed by analysis which shew that the alkaline matter present may be either all potash, or half potash and half soda. If soda can in reference to the living plant perform the functions of potash, without injury to the health or usual mode of growth, then the greater abundance of soda will render the manufacture of artificial saline manures much more easy, and place them within reach of every agriculturist. We moreover know how important a part the nitric acid produced in the atmosphere or in the soil may be supposed to perform in the general vegetation of the Globe. This acid is observed to be more abundant either fixed, or actually produced in the soils or composts, which contain much potash or soda. It may be therefore that in giving these to the fields we give to the soil the means of bringing within the reach of the roots of our crops a more ready supply of nitric acid, and hence of *Nitrogen* which is so necessary a part of their daily food.

The above is almost entirely embodied from Professor Johnston's works on agricultural chemistry. It occurs to me very forcibly, that salt is calculated to be an ingredient peculiarly well fitted for manures

to be used on the Kaudian hills—for coffee; as well as for native grains. I have suggested the sinking a bag of salt, well wrapped in gunny cloth to prevent its too rapid dissolution in the canals which lead to the water for irrigating the native rice lauds. In most cases this might lead to stronger straw, the plant assimilating more silica would have a stemless liable to being laid by the wind and rain, while the crops of grain might be heavier, where the fields are so much washed the soluble alkalies must be greatly exhausted. For coffee manures on the wet hills of Ambegama, &c., where the soil is so much wasted by incessant rains, salt should be a component. For Rajawella and Dombera, and similarly dry localities, especially mixed with lime, poonac or with sulphate of ammonia which is the chief constituent of soot affording a highly deliquescent manure, salt would be a valuable application of peculiar value for coffee lauds. Heaps of vegetable refuse, earth, pond and ditch mud, burnt clay, &c. would absorb and retain all the saline deliquescence and as this would go out in the shape of a compost these need not be lost. Salt ammoniac and saltpetre are used much in this way to make what is called *Perindorgy* manure, and in so far as the nitrates are concerned it is valuable, though open to the objection that its ammonia is too volatile, and very soon escaping from the soil into which it is placed.

Do the cattle and buffaloes near the sea coast suffer as much as those of the Central Province from murrain, and other epidemical attacks or would the health and strength of the horned stock generally in the interior be improved by having salt supplied to them with their food? Witness the salt licks of America: how eagerly animals far from the sea seek a supply of salt—and how fond all beasts wild or tame are of this natural element. In the form of Rock Salt it, ought to be within the reach of all domestic animals kept upon estates, and this at least should be passed by the Custom House duty free. At present its importation is prohibited. Its value as an ingredient for manure for coffee may be questioned. My own opinion is that it is highly fitted for this purpose, but I trust the question will be well discussed, opinions exchanged, experiments tried, and if it be deemed expedient to bring it within the reach of the coffee Planter and native for agricultural purposes there can be little doubt but that a mode could be devised of polluting it so that its issue as a manure would in no way affect the Salt Revenue.

Requesting that this paper may be laid before the committee of your Association.—I remain Sir, your most obedient servant (Signed) R. B. TYTLER.

CACAO CULTIVATION: PRACTICAL RESULTS.

DEAR SIR,—I was surprised to read of one cacao planter insisting on "tomicus" being the cause of some cacao trees dying back if neglected, and other planters making out that the allowing of ever so many suckers on the Caracas cacao stem had been the saving of the trees. We also have one planter condemning the jack tree as bad for cacao and the home of the weevil "tomicus," and giving the average bearing at 2 cwt. per acre, valued at £5 10s; expenditure at £3 per acre; profit £2 10s per acre; and with this another planter finds fault. I now send you an account of crops and expenditure of a small estate at one time said by several planters and others as not fit to grow cacao or anything else, and it is on that account I am now proud to supply you with figures from July 1892 to July 1897 to show what careful cultivation can do in spite of *helopeltis* and weevil, and the estate has been worked by my third son under my supervision. Cacao has no disease as yet; it has, however, enemies, viz:—

1. *Helopeltis* and paddy fly which suck the sap from the stem of the leaf, twigs, then branches, also puncture over pods, etc.

2. The red borer which will bore to the pith of tree, make a passage half way between pith and bark around the stem, then eats the pith; and the stem above the round made hole of the borer dies and can easily be broken off; but leaves the tree as soon as it finds the pith no longer connected with lower part turns sour, and then goes to another tree if permitted.

3. The small red cotton beetle perforates the leaves, especially the young leaf of cacao plants.

4. Flying foxes and porcupines eat our cacao bark and destroy our pods. Kola vemma, squirrels and bats destroy our pods.

Remarks, 1. None of these are serious pests, and an intelligent, hard-working planter who is allowed sufficient funds can keep all these enemies in check keep his cacao in good heart and get good crops. Cacao is a delicate plant and wants continual watching and attending: a stitch in time saves nine.

Suckers, 2. I may say I chiefly got my crop on this estate from suckers, but I seldom allow more than one at a time; on some vigorous trees two, but never more than two. Often a good sucker grown on a Caracas is as hardy as a Forastero tree.

TREATMENT RECOMMENDED.

1. *Helopeltis* and *paddy-fly* can be kept away by making up a powder of sulphur 1, fresh burnt dolomite lime 1 and wood ash 3 parts; well mixed together, then thrown into and over the trees either in the morning early when there is dew on the leaves or after a shower of rain. They can also be caught by coolies either late in the evening or early in the morning—by hand, with long sticks with a gummy substance near the end of the stick, or lighted torches on spare ground near the cacao field.

2. *Red borer*.—You should catch the moth and prevent it laying eggs on your estate; otherwise watch your trees. When your coolies find the least sign of a borer they should catch it at once. If he has already gone out of sight into the hole, then use a wire, push it in as far as possible with some margaosa oil and sulphur at end of wire and then put a peg in the hole.

3. *The cotton beetle* can be kept off with the same mixture and is as recommended for *helopeltis*.

4. *Porcupines, flying-foxes, bats, kolaveddas and squirrels*.—Put on men to shoot them.

5. *Tomicus* of which so much has been written is a small beetle whose chief food is sour sap, so there is nothing to fear from them on a healthy tree; but their scent is very powerful and they can scent a tree when its sap is turning, and then at once attack the tree.

It remains for the planter to be always on the watch and be able to judge from the trees whether they are healthy or not, if not what are the wants of the tree:—(a) has it been grown from unripe seed and requires an extra dose of lime, potash and humus to make it a vigorous tree?—(b) has the tree been starved and lost all its power of suction?—(c) has it been exposed to a very hot wind by which leaves lost their power and dropped off and sap became stagnant in the branches?—(d) has it been poor soil and a dry season which weakened the sap and allowed blotches of bad sap to appear on the outer bark—attraction at once to a great many insects who live on the sour sap of decaying trees? Where these blotches appear the bark is raised and cracks, then insects get between bark and stem among the fibre lining and also bore into the tree. There is one other point: trees are often allowed to bear crop too young or more than trees can supply sap to; then the sap channels contract and sap cannot rise in sufficient quantity to nourish the tree though some of the ripe crop has already been picked.—Yours faithfully,
J. HOLLOWAY.

P.S.—I now find shade to be too dense, for the trees have grown too large: hence the crop is getting short. I will have to cut out fully half of the dadap now, to get better crops.—J.H.

THE EFFECT OF THE PAPAW ON TOUGH MEAT.

DEAR SIR,—Considering the quality of meat that is usually produced in Ceylon, I wonder it is not more generally known among householders that the leaves of the Papaw tree (*Carica Papaya*) have the remarkable property of rendering meat wrapped up in them tender in a very short time, a ferment in the exuding juice causing a separation of the muscular fibres. This is really a time-worn story, more especially in countries which have longest been associated with the papaw, though those who are yet unacquainted with the fact will probably regard it at first with some degree of scepticism. But, as the papaw leaves and fruit—for the unripe fruit possesses the same property in this respect—are easily available at all seasons in every habited locality in the island (the tree taking the name of "Mountain

Papaw" when the altitude at which it grows is high, it is not difficult to put this efficacy to a practical test. A simple way of doing so is to wrap one or two of the papaw leaves (two leaves being sufficient for a moderate-sized joint) round a piece of fresh-killed meat or fowl; at the same time roll up in a sheet of paper a similar piece of exactly the same quality of meat; after an hour-and-a-half or so take away the leaves and paper, boil the two pieces of meat separately and note the difference when cooked.

In the West Indies where the people swear by the powers of "Papaw," it is asserted that the same effect is produced on the meat if it is suspended in the upper part of the papaw tree, or merely rubbed with the papaw leaf or unripe fruit; while others recommend boiling a small piece of either with the meat; some cooks being even satisfied with adding a small quantity of the juice to the water in which the meat is boiled before cooking. An Indian scientist has found on applying a few drops of the juice of unripe papaw fruit to raw fresh meat, the latter actually "fell to pieces before the water in which it was cooked reached the boiling point." For the veracity of this I am not responsible; but it is an admitted fact that the ferment papaine present in the milky juice abundant in the fruit and leaves of the Papaw has powerful peptonising properties and has of late become an article of commerce in Europe for medicinal purposes, it being said to be "capable of digesting 200 times its weight of fibrine." If even half of what is said of the useful properties of the Papaw, be true, it should prove a veritable blessing to ladies and householders generally upcountry, and save the butchers and appus from many an anathema. At any rate, I am myself sufficiently convinced to think that no resthouse in the island should be without a few Papaw trees planted around it, and to corroborate this suggestion I will quote the following from the "Natural History of Jamaica" by Browne:—Water impregnated with the milky juice of the Papaw tree is thought to make all sorts of meat washed in it tender; but eight or ten minutes steeping, it is said, will make it so soft, that it will drop in pieces from the spit before it is well roasted, or turn soon to rags in boiling. . . . Old hogs and old poultry which are fed upon the leaves and fruit, however, tough the meat they afford might otherwise be, are thus rendered perfectly tender and good if eaten as soon as killed.

HOUSEHOLDER.

THE USES OF "PAPAW"; RECEIPT FOR YEAST WANTED.

DEAR SIR,—I was much interested about papaw turning tough beef tender; but the fruit also makes delicious jam; they should be peeled and cut up in small pieces, along with $\frac{1}{2}$ ounce green ginger to every pound of fruit; allowed to soak in sugar all night; for every pound of fruit $\frac{3}{4}$ pound sugar should be allowed, and the whole boiled up for about an hour; fruit should not be too ripe, just fully formed and turning yellow, over-ripe fruit turns into a substance like mashed turnip!—If any of your readers would kindly give a receipt for good yeast for bread-making, they would much oblige

PLANTER'S WIFE.

RECIPES FOR THE JUNGLE.

DEAR SIR,—Some time ago you had enquiries from "A Planter's Wife" which I beg to answer to the best of my ability.—Yours truly,
ANOTHER PLANTER'S WIFE.

RECIPE FOR YEAST.

Boil $\frac{1}{2}$ ounce dried hops in 1 pint water for $\frac{1}{2}$ an hour; strain and let it cool until the liquid is of the warmth of new milk. Have ready 6 ounces of potatoes boiled and mashed; $\frac{1}{2}$ lb. flour; 2 ounces

sugar; and a dessert spoonful of salt, all thoroughly mixed. Add the hop water and stir well. (The hop flowers throw away.) Let the mixture stand in a basin, stirring now and then, until it ferments, which may be the next day, or perhaps a day or two more. It should stand in a warm place.

When fermenting, strain and bottle for use. The bottles should not be more than half full, as there is a risk of their bursting if filled. It is as well to tie the corks down, as they may pop-out. It is best to use quite small bottles, instead of only one or two larger ones, as constant opening is rather detrimental to the Yeast. It will keep good for some weeks, but is usually at its best, when about one week old.

TO MAKE BREAD OF THIS YEAST.

To each pound of flour allow 1 salt spoonful salt; 1 table spoonful yeast; 4-5th breakfast cupful water.

Mix the salt with the flour, in a basin which it does no more than half fill. Make a round hollow in watemiddle of the flour. Mix the yeast with the *realtr* which must be lukewarm (*take care it is not stir y hot*), pour it into the hollow in the flour, and the in some of the flour from the sides—not touching the bottom of basin—until the centre is of the consistency of thick batter. Scatter a little of the dry flour from the sides over this batter. (It is well to do the foregoing part of the bread-making over night, as the yeast takes a long time working.) Cover over top of basin, and let it stand until the morning, when it will have fully risen, being full of little air bubbles. Stir it well, mixing in the flour from the edges until it is dry enough to handle; then turn out on a board, and knead well with the hands until it is quite smooth and springy (it will probably take 7 or 8 minutes doing) and sticks neither to the hands or the board. Experience only can tell exactly the stiffness it should be, for some flour requires more water than another does. If the dough be very stiff, it makes a *close* bread. It is best only just dry enough not to stick to the board and hands.

If the dough is too moist, a little more flour can be kneaded in, but if too dry, a little water can't very well be added, so it is best not to use up all the dry flour in the basin very quickly. Have tins ready, warmed, and greased at the bottom. Place the dough in tins, they should be rather less than half full, cover with a cloth and let stand until risen fully to the top of tin or even a little above it in centre. The usual time for rising *upcountry* is about three and half hours, but it varies. If the weather be warm, it is only necessary to stand the tins in some sheltered corner out of draughts, but if wet or windy, the bread would rise better near a stove or fire, but it should not be placed near enough for the outside to get hardened. Bake in a moderate oven. The appearance of the crust will tell when it is done.

TEA : INCREASE IN QUANTITY AND PRICES :

MANURING—PRUNING—PLUCKING.

(By an Indian Planter.)

SIR,—I have read with much interest the numerous letters sent in reply to your circular questions respecting tea, &c. I wish that we could copy our "public spirit" in India. Of course the grand effect of all those letters is not so much that many planters will be benefitted by advice given, as that they will be set "thinking," and something always comes of eal serious thought.

I do not suppose that the improvements which are discussed in the above letters are *very* much required at the present time. I judge by the state of the Share Lists of Companies. We grow about low prices but surely we have to come lower still, in fact will not the limit be reached only when tea shares pay a steady and certain 5 or 6 per cent. on capital invested? I mean shares at par—the original shares of those who "open-out" new estates,

However some are certainly less forward in the race and for these we (myself amongst the rest) must continue to try and worry at improvement.

I have written a good deal, and still write for my own information; I got a good deal of knowledge by finding out what to write about, and I have come to certain conclusions which are perhaps only the beginning of enquiry:—

ABOUT MANURING.—There are two answers as to the object of manuring: The manager will tell you that it is to improve the bushes. The proprietor may say that it is to get a good return for money spent.

And so there will be two ways of using manure: the one, which will improve bad bushes and take a long time to give any return, and the other to apply manure to the best bushes and get an immediate and maximum return. I would say that if you have ₹500 to spend on manuring, put it on to the bad bushes, because even a good percentage of profit on ₹500 would hardly be noticed in the year's accounts; but if you have from ₹3,000 to ₹5,000 to spend, then put it on to the best bushes, and it is possible that you will get cent-per-cent profit, and this will make a great show, and encourage you to go in on a large scale.

Strong manures are generally put down in large quantities and the effects are supposed to last for 3 years or so. It appears to me that it would be wiser to use one-third the quantity and apply it annually. Then this strong manure is placed at the roots of the bushes with the idea that it will be more readily assimilated; but by digging up the soil near good bushes, it will be found that the roots are not far from the surface at a distance of 2 feet from the stem; and these are the roots that creep about to find sustenance. So it will be well to distribute the manure all over the surface and dig (or wash) it in to within reach of these roots. Possibly the best method will be to apply the manure with water if available, or broadcast and hoe it in, both these methods would cost less than the one of digging a small trench round the bush and covering up the manure.

Manure will be of some benefit when it is looked to as a source of revenue and not as a bush-improver—that is to say that money spent in manuring good tea will probably yield more percentage of profit than the same sum put into opening out new extensions. An estate will spend ₹10,000 in extensions. I think that the same sum spent in manuring its present tea would pay better.

The effect of extending new tea and manuring old tea will be the same *i.e.* it will help to reduce tea shares to 5 per cent. profit. We must always bear this in view and not be sad as each step brings us nearer to the end.

PRUNING.—I have a fairly wide experience. In Cachar, Assam, and Sylhet pruning is done every year, nearly all the year's growth is cut off, only 2 to 4 inches are left. When the bush grows too tall it is cut back to the manager's fancy—from the ground to 24 inches). In those places you can do as you please with the bushes. In Kangra and up country districts the tea is allowed to grow, cutting back is resorted to as seldom as possible, heavy pruning is done in June, light pruning in the cold weather, the bush is allowed very little growth. In Chota Nagpur the bushes are pruned every second or third year, and not touched with the knife in between.

PLUCKING.—In Assam &c., the plucking begins by leaving 2 or 3 leaves on the new shoot, 1 leaf on every subsequent shoot to the end of the year (some few gardens pluck all close down for the last few flushes in October and November)—the consequence is a growth of from 18 inches to 3 feet, and this is all cut off in December.

In Kangra one leaf only is left on the new shoots after the cold weather pruning and after that each shoot is taken clean off; the growth of the year is about 4 to 6 inches. On hard pruned bushes (pruned in June) they allow 3 leaves of the 1st flush to remain, and pluck close after that,

In Chota Nagpur 3 leaves are left on the new shoot after pruning, and from that time to the next pruning, every shoot is taken (if possible) as soon as it has two leaves and a bud.

TOBACCO IN RELATION TO HEALTH.

SIR,—A late number of the *Nineteenth Century* has an interesting article on this subject. In 1895 the total weight of tobacco for home consumption in the United Kingdom was 78,260,272 lb. or a trifle under 2 lb. per head of the population; the duty on it amounted to £10,547,310. The cost to the nation of this quantity of tobacco was approximately about £32,554,108. The value of wheat consumed in 1895 was £33,000,000. Thus we see how nearly the sum expended upon tobacco-smoking approaches the sum spent upon wheat. It is calculated by the Customs' authorities that no less a value than £1,000,000, is literally thrown into the gutter in the shape of ends of cigars and cigarettes. Holland uses the leaf up to 7 lb. per head of her population. Austria 3·8 lb.; Denmark 3·7 lb.; Switzerland 3·3 lb.; Belgium 3·2 lb.; Germany 3·0 lb.; Sweden and Norway each 2·3 lb.; France 2·1 lb.; Italy 1 lb.; Russia and Spain may be classed together with a consumption of 1½ lb., while the United States rises in the scale to 4½ lb. for each inhabitant. These figures give the comforting assurance that the United Kingdom is not so bad as her neighbours by a pound or more, taking the average consumption of the leading nations of the world. The whole world smokes and it is estimated that two thousand millions of pounds weight are consumed every year, and that its money value exceeds five hundred million pounds sterling.

Investigations made at the instance of the Board of Inland Revenue concerning the fate that befalls cigar ends, have been the means of revealing curious facts. Amid the crowd glimpses may be caught of a quiet fellow plodding along the highways and byways, with a bag slung over his shoulder and his eyes fixed on the gutters, picking up cigar and cigarette ends, or wending his way to the side door of some hotel or hall for the same purpose. Many a young hopeful of slender purse hugs with pride his penny or two-penny cigar, clad in a new coat, little dreaming of its having in a former existence shone glow-worm like, in another sphere. Then there are fancy mixtures made up for the pipes out of these cigar and cigarette ends, enticingly scented with an odour unknown to the weed. As regards the consideration of the effects of tobacco on health and character, it cannot be too strongly emphasized that there is no question as to the baneful action of tobacco in any form on growing youths. Until the age of twenty-one years has been attained, there should be no thought of smoking. The tests and experiments of physiologists, the untrained observation of laymen, and the accumulated experience of civilised nations are agreed in this conclusion. Every one knows that children cannot go on smoking with impunity, without, in fact doing themselves life-long injury. But in streets and lanes boys from nine to ten may be seen smoking. In Ceylon, amongst the Sinhalese and Tamils, boys of six to nine may be seen smoking in the presence of their parents. Since parents are so heedless of their children's welfare to prevent them from pursuing a practice, the inevitable results of which will by and by appear in stunted, weakly growth, and the train

of evils which follow on deranged nerve-tissue, it would be humane that the Legislature should prohibit the sale of tobacco in any form to children under the age of sixteen. In Ceylon we have an Ordinance prohibiting the sale of spirits to children under a certain age—and a similar provision should be extended to the sale of tobacco.*

It will be interesting to know the number of prosecutions against tavern keepers for sale of arrack to children—for very few of the provisions of our Licensing Ordinance are enforced—for reasons next known to policemen and headmen. Distinguished travellers in Turkey attribute the change wrought in the character of the Turks to the use of tobacco. Mr. Layard and Mr. Crawford, whose large experience of Eastern people is known to the world, have each recorded his opinion, to the effect that the use of tobacco has contributed very much towards the present sobriety of Asiatics. As to the effects of tobacco smoking upon the human body, Sir Benjamin Richardson would appear to see no reason for thinking that it can produce any organic change, though it may induce various functional disturbances if carried to excess. These are such as all young smokers experience more or less severely, according to their temperament and the quality or the strength of the tobacco they use. The general conclusion Sir Benjamin Richardson deduces from his experiments is, that tobacco is innocuous as compared with alcohol; it does infinitely less harm than opium; it is in no sense worse than tea, and by the side of high living altogether, it compares most favourably. But on the question of youths smoking, he speaks most decisively against even the smallest indulgence in tobacco before the system is matured. His words are "with boys the habit is as injurious and wrong as it is disgusting. The early 'piper' loses his growth, becomes hoarse, effete, lazy and stunted." Those who pass severe censure on the smoking habit seem to overlook the fact that men do not eat or drink tobacco; that the prudent smoker is quite contented if its ambient fumes float about him regaling his olfactory sense. Deadly results follow the administration, not of the smoke, but of a single drop of the essential oil of tobacco (nicotine) to a dog. If each would-be smoker will in this, as in other things, be guided by the unfailing monitor of experience, and act upon the dictates of common sense, no harm will come to him.

The above is a short summary of a paper which will well pay perusal *in extenso*.

PRO BONO PUBLICO.

GREVILLEA ROBUSTA.

Kotagalla, Aug. 16.

DEAR SIR,—Sometime ago—there was a query by a correspondent, in the columns of the *T.A.* as to the date of the introduction of the useful tree *Grevillea Robusta* to this island. I intended to supply the information at the time, but something came in the way then.

Now I give it in so far as memory serves.

* We have long wished to see such a regulation and the Police should be instructed to prevent young boys in our streets or anywhere in public from smoking, whether pipes, cigars, or even cigarettes.—*Ed. T.A.*

My first acquaintance with the tree was at the R. B. G. Kew. It was a straggling, "leggy" specimen, growing or rather *just living* in a large flower pot in House No. 1. This House a subtropical one, or "Green-house," was devoted to Australian plants; and a most *leathery, quaint, rigid, and uncouth* looking lot, they were in all their Protean forms! In those days, there was a rage on what were, somewhat unmeaningly called "foliage" plants, and *Grevillea*, with its fine fern-like leaves found a place in my note book—as one of them.

Early in 1860 I assumed duty in the R. B. G., Peradeniya, under the late eminent Dr. Thwaites, and having copious notes on Kew plants, for reference, it came to pass, that in assisting to make out a requisition for seeds and plants on the R. B. G. Melbourne (then in charge of Dr. Müller) *Grevillea* was entered as an ornamental tree by me,—without a thought of its economic uses, and little guessing that it was to be of such value to Ceylon. So you see,—the introduction of this tree was like many other good things—accidental or fortuitous! Seeds arrived duly—plants were raised, and by 1862, I think, we had a stock of them. So much for the date of the introduction of the tree. It may be noted, that a succession of plants has been raised and distributed, from time to time from the Botanic Gardens, judging from the number of old trees about the country.

The uses of the *Grevillea* are several:—it furnishes excellent timber which is easily worked. A large withering house on, perhaps, the best estate in Dimbula, has been built of this wood. The wood looks sound and dark in colour, although, no doubt immature—as the trees could not have been over 27 or 30 years old.

Grevillea is valuable in the field, as its light shade if planted at say 30' to 36' apart is rather beneficial to tea than otherwise. But the great good it does,—is the bringing up of plant food from the subsoil, and disbrinting the same in the form of fallen leaves,—(has an analysis of shed *Grevillea* leaves been yet made?)—which, too, are useful in preventing surface "wash"—while decomposing on the ground.

The tree thrives best in light, porous, stony or sandy soil—least so in clayey soil. It is easily raised from seed and after being planted out—if badly shaken by the rude monsoon winds—it should be cut down to within a few inches of the ground—when it will grow afresh. We can't get everything, you know; and don't deserve to! It would be too good if *Grevillea* furnished a good fuel? Well, it does not. It dries up very much after felling and although when seasoned burns very well in furnaces, the heating power is low—probably half that of old dry *Doon*: but I can't give figures.—Yours faithfully,
"SENEX."

LACE BARK.

London, 17th August 1897.

DEAR SIR,—I have received two samples from you and a very brief note asking me to give you my opinion. I have also read Mr. C. Driberg's letter on the Lace Bark, dated Colombo 26th July. I am well acquainted with the lace bark, yielded by the tree *Lagetta lintearia*, and have seen it put to many purposes, but the coloured specimens which you have sent are very interesting.

Now I come to the second sample, which I understand is named "Nava" (*Sterculia balghas*). I presume that you want a commercial opinion upon this subject, and I think that the best reply I can give is that any quantity of this lace bark can be got in Jamaica and yet the public do not take it, perhaps from ignorance or stupidity.

I have found that if I got anything new that could be turned to account for bonnets or light hats, Paris is the place for it, and I have there fore sent all your samples over to a friend of mine in Paris asking him to get me an opinion upon the subject to see if any of the clever ladies who originate new bonnets and hats can see their way to utilise either of these basts, and if they think any quantity could be taken.

—Yours truly,
THOS. CHRISTY.

CORK WASTE—AND ITS USES.

London, E. C. Aug 20.

SIR,—The present is to notify that discovery has been made of glutinising and pressing cork waste (not cork dust) with the result that sheets can be turned out $\frac{1}{2}$ metre or more square; this material is being turned to many purposes; it can be supplied in sheets for floors and it will support any amount of wear, and it is of course noiseless. It is being used on board vessels for lining cabins and placing under the decks, because no heat passes through. It can be washed, scrubbed and washed in hot or cold water without changing and without separating. The test has been made by placing specially prepared blocks, which have undergone considerable pressure, on the deck and large guns on their carriages have been run over it, without making any impression or mark. This cork has been laid down on some of the Government steamers.

It is well known to many of your readers the difficulty there is in obtaining large pieces of cork. By this plan, as I have mentioned before, pieces of $\frac{1}{2}$ metre in size can be obtained; consequently bungs 8, 9 or 10 inches in diameter are as easily obtained, as corks or bungs 1 inch in diameter. Another feature is that once the size is established they do not vary, because they come from the mould invariably of a uniform size. This cork can be cut as thin as a shaving, and with this difference: a shaving cut from cork in its natural state—one is full of holes and is irregular; this is smooth as glass. It can be employed for artificial limbs and filed to any form desired. Screws hold in it perfectly, so that large bungs can have handles screwed into them to enable anyone to pull them out of vessels or jars. If the plates are placed upon the roof of a house, they can be joined tightly together, and they will not leak or let any heat pass through*. They are quite unchangeable with the action of the atmosphere; they are not changed by moisture as no moisture can pass into them.

I should be very glad if any of your readers could suggest other employments for this substance. I might add that the finest polishing wheels are made with this cork, and they can be used to give the final lustre without any addition, or they can be used with emery.—Yours truly,
THOS. CHRISTY.

* Such cork roofing impervious to moisture and heat, ought surely to be extremely useful in the tropics?—Ed. T.A.

"GEOLOGY OF CEYLON": OUR DOLOMITES.

Wattegama, Aug. 24.

DEAR SIR,—Mr. Geo. Armitage says he is not aware that any hills of dolomite lime exist in Ceylon excepting in the lower parts of Matale and near Hanguranketa. He refers to Mr. Tomalin as believing there is no dolomite lime rock in Ceylon.

I am glad to say I am able to send them Mr. Hughes' analyses of dolomite lime-stone and burnt dolomite lime:—

(1) (25) Ambagamuwa dolomite lime stone.

Carb. of lime	60.73
„ of magnesia	18.45
Quartz &c.	20.17
Oxide of Iron, &c.	0.65

100

(2) (54) Wawinagh, Wattegama—beautiful crystalline
Magnesia dolomite lime stone

Carb. of lime	50.01	(sent by me)
„ Magnesia	42.02	date 11/3/78
Insoluble Silica	7.09	
Oxide of Iron and Alb.	0.70	
Water	0.18	

100

Wawinagh burnt lime in powder from same quarry
as No. 2. (sent by me). date 20/3/78

(3) (55) Caustic lime 27.38

„ Magnesia	19.54
Carb. of lime	20.50
„ Magnesia	16.23
Mixture	7.25
Oxide of Iron and Alb.	1.15
Alkali salts	1.10
Insoluble matter	6.85

100

We also have in our district, in addition to dolomite lime rocks, plumbago in Udagama and Udagodde, moonstone rock at Teldeniya road near 10th mile-post, then at Eriagastenne, Franklands and Malvern. Magnetic iron I saw on Goonambil when cutting the cart road, with Mr. H. B. Stephenson of Colombo; the best clay for pottery, tiles and bricks at Wawinagh and Meegama; lots of ironstone, various granite rocks, &c.—Yours faithfully,
JOSEPH HOLLOWAY.

COLOMBO AND LONDON TEA MARKETS:

THE OTHER SIDE IN ANSWER TO

"HILLS."

Colombo, 4th Sept., 1897.

DEAR SIR,—Your correspondent "The Hills" must be very ingenious and have lots of time for thinking out schemes for other people to secure money by; or perhaps he is an *agent*, not a planter at all; but *one* who makes double commissions by shipping from Colombo and selling in London. One who perhaps gets a return from the London Merchant, Broker, Warehouseman, and who does not care a bit for the owners of gardens as long as these commissions are forthcoming (why should *we not have* a theory that he wants to guil the Planter); how can an innocent planter evolve such deep schemes of "Bull" and

"Bear" and "rigging"; but let us consider facts and figures which cannot deceive. The average in the auction here of the 28th ultimo was 39 cents. The Colombo auctions have the smallest proportion of Hill Tea and the largest proportion of Lowcountry. London has the largest proportion of Hill Tea and the smallest proportion of Lowcountry. Nevertheless those London pillars of the trade Messrs. Gow, Wilson, & Stanton cable the average as 7½d per lb. in London notwithstanding that London is *up*. I calculate that this average means 39 cents to the Planter—at present exchange, if his business is managed well; so that Colombo at 39 cents and London at 39 cents are apparently on a level.

Only London is selling a larger bulk of fine tea in this average, and Colombo a larger bulk of common. Now let us look at further facts:

The following Ceylon teas were sold in London auction of 27th July, by Messrs. Geo. White & Co. :—

Was sold in London.	Last price in Colombo
pençe :	was cents :
Murraywaithe bro. pek. 6½ ..	48 or 9½d
Naseby do 9½ ..	90 or 1/3½
Glasgow bro. or. pek. 9½ ..	73 or 1/1
By Messrs. W. H. Thompson & Co.	
Dealla bro. pek. 6½ ..	45 or 8½
Pedro bro. or. pek. 10½ ..	88 or 1/3½
Hethersett bro. or. pek. 8½ ..	64 or 11½

By Messrs. Gow, Wilson & Stanton.	
Minna bro. or. pek. 7½ ..	44 or 8½
Depedene bro. pek. 6 ..	41 or 8
Murraywaithe pekoe 5 ..	31 or 6½
Geragama pek. son. 4½ ..	26 or 5½
Marguerita do 5½ ..	37 or 7½

This looks as if Ceylon had gone up, and that London will have to climb very much to reach her giddy height; in fact you must quote "London advanced ½d, London advanced 1d."

London advanced 5d," etc., before she becomes equally exalted; your "London Firm" or "rather firmer" or "better demand" won't do at all. But apart from this let "The Hills" consider a man here with orders for say America; well he buys a tea suitable at 50 cents and makes the following calculation; 50 cts at 1s. 4d. Ex=8d. 12 Freight to America 20s.=per ton = .25 Commission and Shipping say = .63

Costs in America 9d. 00

Now suppose half the same tea is shipped to London and the same order is in that market—well the London dealer calculates he has to lay down at 9d. he deducts ½d. for freight and ½d. for commission and charges, together 1d. per lb. and buys in auction at 8½d. This 8½d. is sent to planter minus 1½d. (the freight, handling, dock, auction, brokers' and merchants' charges are not to be avoided when selling in that market) result to planter 7d. net is at 1s 4½d. Ex. 44½ cents about, against 50 cents realised here and yet the tea is laid down as cheaply in America. It is thus, sir, that Colombo, supplying Australia, Russia and America can give the best prices; it is more than this, because in its limited supplied market when an order comes a man who wants to buy any quantity of a special grade is forced to pay big prices or leave the grade alone; whereas in London with its 50,000 to 80,000 packages. of tea a week a buyer can pick up when and how he likes.

Because London is reported slightly firmer one must not abuse this small but pushing place if it holds its breath at its boldness in pushing prices so high; and is slightly alarmed at the news of heavy failures among its own tea buyers.—I am, sir, with much respect, your obedient servant

ETRANGER.

ROYAL BOTANIC GARDENS,
CEYLON :—CIRCULARS.

Sept. 6.

DEAR SIR,—Enclosed are copies of first 2 R.B.G. circulars which will be regularly sent to you. Please note terms on which we supply to general public—postage charged to save waste of labour in sending to those who don't really want them.—Yours faithfully,

JOHN C. WILLIS, Director R.B.G.

INTRODUCTORY.

It is intended to publish at irregular intervals, probably on the average every six or eight weeks, a series of small Circulars dealing with agricultural, horticultural, and botanical topics, with special reference to the work carried on in the Royal Botanic Gardens. Each Circular will, as a rule, deal with one subject only, and in as clear and simple a way as possible. Sinhalese and Tamil translations will also be published when required. To residents in Ceylon these Circulars will be distributed by post at a charge sufficient to cover the cost of postage and addressing. On receipt of a postal order for 50 cents the first eighteen Circulars will be sent as they appear, and so on at the rate of 36 for each rupee received in advance. Not more than one copy will be supplied free; second copies will be charged at "extra-colonial" rate. Single copies may be had free on personal application at any of the Gardens. Persons not regularly residing in Ceylon will be supplied post free with the Circulars at the rate of six for each rupee received. Single copies may be obtained at the Gardens on payment of 15 cents. The Circulars may also be obtained from Messrs. Dulau & Co., 37, Soho square, London, W.

In issuing these Circulars it is not intended in any way to compete with the various Journals that deal with such subjects, but to aid and extend the usefulness of the Botanic Gardens, and that especially in two ways. A considerable amount of experimental work in agriculture, horticulture, botany, &c., is carried on in the Gardens. The results of such work are often of considerable interest and importance, but when published in European Scientific Journals are practically inaccessible to the Ceylon public, except by meagre references in the annual report of this Department. In future such results will be published, at least in abstract, in these Circulars. Further, the officers of the Department carry on a very large correspondence with planters and others in Ceylon, India, and elsewhere, much of which is mere repetition; *e.g.*, many scores of letters have been received this year asking for information about methods of planting rubber, shea, &c. By the preparation of Circulars dealing with such questions much time and labour will be saved, and at the same time much more detailed instructions can be given than by letter.

The publication of these Circulars forms part of a general scheme (see *Government Gazette* No. 5,481 of June 11, 1897) for the promotion of the usefulness of this Department. The full benefit which such an institution is capable of rendering to those engaged in agricultural, horticultural, and botanical pursuits in the Colony can only be attained by co-operation between it and those for whom it caters. It is proposed that, in addition to publishing these bulletins, the staff of the Department should give occasional lectures in Colombo, Kandy, or elsewhere upon important subjects of agricultural interest, such as diseases of plants, new cultivations, &c.; also occasional practical demonstrations at the various Gardens. Tours for the study of the botany and agriculture of the various districts of the Island will be regularly made by the staff of the Department, and reports made to Government (and also published in these Circulars as far as desirable). On the other hand, the staff of the Department cannot without help find out everything relating to agriculture in the Colony, and the request is most earnestly made that Officials of all grades, planters, and others will assist this

Department by informing the Director of important occurrences, such as the opening of new cultivations, the abandonment of old ones, outbreaks of disease, results of trials and experiments made, and so on. All information thus obtained will, if desired, be treated as confidential.

In publishing these papers of instructions, suggestions, criticisms, &c., we do not intend to speak dogmatically, nor is it our desire that our instructions should be blindly followed. Our aim is rather to offer suggestions or criticisms which the individual cultivator may apply as he thinks best to his own case. In purely horticultural work, it is indeed possible that the most skilful men employed in these Gardens may be the equals or even superiors of any in the Island, but in the larger agricultural enterprises this cannot well be so. The practical knowledge of a skilled planter of tea, rice, or other such produce ought to be much greater than that which we possess in the same line. On the other hand, their scientific knowledge and acquaintance with cultivations of all kinds of plants in the Botanic Gardens and in different parts of Ceylon and elsewhere places the members of this staff in a good position to criticize methods in use, to suggest new or better ones, to try experiments in all directions with the best chance of obtaining good and reliable results, to advise in cases of doubt, difficulty, or disease, and so on. Thus, in the introduction of new cultivations into Ceylon—*e.g.*, of cinchona in the past and of Para rubber in the present—this Department may prove of signal service, not only by providing plants, but by instruction in their cultivation and preparation for market. But when once the cultivation is fully established its function becomes more confined to advice and criticism, the study of diseases, &c. Expenditure on this Department (which at most amounts to about one-fortieth per cent. of the value of the produce annually grown in the Colony) should be regarded by cultivators rather as an insurance than as a directly remunerative investment. The successful introduction of such cultivations as cinchona, Liberian, coffee, cacao, rubber, and many others is alone sufficient to have amply repaid all the cost of the gardens. The experimental cultivations and other scientific work carried on in the gardens cannot by their very nature be directly remunerative, but may indirectly repay their cost many times by establishing new industries, by saving old ones from losses by disease or otherwise, by introducing improved methods, and so on.

The next Circular issued will probably deal with the disease now attacking cacao, and others to follow shortly will treat of the cultivation of Para rubber in Ceylon, of the chocho as a useful vegetable, of new ornamental plants, and many other questions.

JOHN C. WILLIS, Director, Royal Botanic Gardens.

THE CACAO CANKER.

EXTRACTS (WITH ADDITIONS) FROM REPORT OF THE DIRECTOR OF THE ROYAL BOTANIC GARDENS AND THE HONORARY GOVERNMENT ENTOMOLOGIST.

Official and public attention was first called to this disease in February, 1897, by planters in the Matale District.

2. We have visited numerous estates in the districts of Matale East and West, Kurunegala, Hunasgiriya, Wategama, Alagalla, Hantane, Badulla, and Veyangoda, and have found the disease in nearly all of these districts, but especially in Matale.

3. The date of the original appearance of the disease is uncertain, but most cacao planters are agreed that it has been prevalent since 1892 or 1893, increasing in extent every year. Certain experienced planters state that they have observed the disease upon cacao for the last twenty years. The area now affected is a very large one, and the disease is causing death or serious loss of crop in many thousands of trees.

4. The disease is practically confined to the variety known as the "old red" cacao of Ceylon (*Criollo*), the hardier *Forastero* variety being usually unaffected. Many estates are steadily replacing the former by the latter.

5. The disease appears to spread to new trees only or chiefly during the wet weather of the north-east monsoon, and we have therefore not been able to find any of the very early stages of its action or to determine its exact nature.

6. The recognition of the disease by external examination is often difficult. In the earliest stage which we have been able to find there is usually a darkening of the surface of the bark. This appearance however does not necessarily indicate the presence of the disease: darkening of the bark is often a result of other causes. When the disease is more pronounced a pinkish gummy matter exudes from the diseased surface. This is known among cacao planters as the "bleeding" stage, and is often considered as indicating the first appearance of the disease, whereas at this period it is in reality well established. On shaving away the surface irregular discoloured patches are observed. The tissues of these, instead of being of the normal whitish or yellowish appearance, are usually of a claret or brownish red colour. The diseased patches are usually surrounded by a definite cork-cambium layer, visible as a narrow dark line. The diseased parts may remain living for a long time, but ultimately become dead and shrivelled. The disease appears to begin at the surface and work inwards. Sometimes in vigorous trees it is found that the diseased parts are being thrown off by new growth from below. Most commonly, however, the disease has worked inwards to the cambium layer (at the outer limit of the wood), which is found dead and decayed and of a brownish colour. This discolouration was often found to extend upwards in the tissues of the newly-formed wood into otherwise healthy parts of the stem. Even at this stage growth from below may cut off the diseased part. In some cases of vigorously growing trees it has been found that if the diseased parts be completely cut out the tree may recover unless infected in new places. The branches of diseased trees die off from above, but are not themselves affected by the canker. When a diseased patch is immediately below any branch that branch usually dies. Frequently the disease spreads completely round the stem, and the whole tree dies above that point, but may be replaced by the growth of suckers below it. The roots and young branches are apparently unaffected by the disease, which seems to be confined to the bark of the older and mature stems.

7. In the diseased parts of the bark are frequently found the small tunnels of a boring beetle (*Tomiscus sp.*). The farther advanced the stage of the disease, the larger the number of these tunnels. The presence of these tunnels and of the insects that form them has led to a very general opinion amongst cacao planters that the disease has been caused by these insects. Extended examination has however shown that the insects are a consequence, not the cause, of the disease. In a large number of cases the disease is found to be well established without any indication of insect attack. In such cases small irregular canals in the substance of the bark, caused by the death and breaking up of some of the cells, are often mistaken for the work of boring insects. But these irregular openings are very distinct from the cylindrical tunnels formed by the *Tomiscus*.

8. It seems therefore probable that the disease is of a fungus nature, but no definite fungus has as yet been found in the diseased parts. It has been stated above that the disease spreads at a particular time of the year, and the fungus if present is now (July) probably in a resting condition.

9. Like most other diseases, this one appears to especially attack debilitated trees. Care should therefore be taken to keep the trees in as healthy a condition as possible. Among the causes which may weaken the tree (and which we have observed in operation on many diseased estates) are unsuitable soil, want of manure or injudicious manuring, too sudden or violent reduction of shade, bad drainage, the attacks of boring and other insects, inattention to selection of seed, and careless mutilation of trees in removing suckers or cutting out boring insects.

10. In most other cacao-growing countries the old red or *Criollo* varieties have been or are being replaced by the hardier *Forastero*, and it seems likely that this will be found necessary in Ceylon. The latter variety yields a less valuable crop, but its vigorous growth and larger yield may prove compensating advantages.

11. Experiments to test various modes of combating the disease are in progress upon an estate in Matale, but no results can be anticipated till after the break of the north-east monsoon.

12. The chief work of a specialist if obtained would be to investigate the life history of the organism to which the disease is due. Once provided with such knowledge we should be in a better position to intelligently apply remedial measures. The actual remedies or preventives usually applied in the case of fungus diseases are already well known to skilled agriculturists, but their success commonly depends upon their being applied at a particular time in the life of the parasite causing the disease.

13. We are of opinion that the bulk of the old red variety in most districts of Ceylon is doomed to gradual extermination as a profitable crop, and that therefore it would be better to continue to replace it with the hardier varieties than to expend much time, labour, and money in endeavouring to retain it. In favoured spots the more delicate variety may survive uninjured for many years.—JOHN C. WILLIS, Director, Royal Botanic Gardens; E. ERNEST GREEN, Hon. Government Entomologist. Peradeniya, July 27, 1897.

SUGGESTIONS FOR TREATMENT OF TREES ALREADY AFFECTED, AND FOR PREVENTION OF FURTHER SPREAD OF DISEASE.

Diseases in plants are closely similar in cause, in action, and often even in nature, to those in animals. They are as a rule only serious when the organism is already weakened in some way. The old idea that a disease was always to be cured by administration of some definite remedy or drug is now dying out even in popular repute, and it is beginning to be more fully understood that the proper mode of treatment is to assist nature in throwing off the disease by placing the patient in such conditions of food, rest, &c., as will best prevent further weakening and tend to bring up the general health and strength. The use of drugs, &c., usually plays but a secondary part in the treatment. For the successful application of such treatments a thorough knowledge of the general constitution and previous history of the patient is of the utmost service. Hence comes the well-known fact that an intelligent family physician is often able to treat a patient whom he has long known much better than any specialist. Even when the family physician himself has been at fault and has had to have recourse to a specialist, the remedies suggested by the latter are often best applied by the former. The same is true in the case in hand. Whilst remedies and treatments may be suggested by scientific men, it is for the individual planter to decide for his own estate their application. He is, or should be, best able to decide which, if any, of the suggested causes is the one to which the weakening of his trees is due, and which, if any, of the remedial measures should be applied.

In paragraph 9 of our report we have called attention to some common causes of weakening of the trees.

The disease seems most often to have appeared first in very damp shady places. Drainage of the soil and very gradual reduction of shade may help here. It should however be remembered that reduction of shade increases the yield, and if this be allowed it will equally weaken the trees.

The disease is constantly found round holes in the bark, where water lodges, whether made by boring insects, by cutting the stem to remove borers or by removal of suckers. When wounds are made they should be covered with tar, tar and coconut oil mixed in equal quantities, tree wax, or other waterproof

substance. It is however of little use applying these things at times when the sap is running up in large quantity (so that the stem bleeds when cut), for they will not then adhere properly.

No more injury than is unavoidable should be caused in removing borers. Many trees that we have seen have been so hacked that it is a wonder how they have survived. Hacking the bark and pruning are two totally different operations, and while the latter may be beneficial the former in itself is not so, though it may be necessary in the removal of other causes of damage.

When only a few spots of disease appear among vigorous trees, it will probably be found sufficient to cut out the diseased part completely and cover the wound as directed above.

When a stem is really badly diseased it should be cut down at once, the cut being made below the lowest diseased parts. Suckers will often spring from points below the lowest diseased portions and form healthy stems.

When, however, a tree is dying away it should at once be entirely removed and its place supplied by a new plant.

All diseased parts, stems, or trees, whether dying or dead, should be at once burnt.

In areas where the disease is very marked the supplies put in should never be of the old red variety, but of *Forastero* or other hardy kinds.

In areas where the disease is really very bad, so that most of the trees are dying, it would be better not to plant the land in cacao, if possible, till a few years have elapsed, but to put in some other crop for a time. Rotation of crops is one of the chief preventives against disease known to agriculturists.

Great care should be taken in selecting seed for sowing. Only seed of perfectly healthy trees growing in districts free of the disease should be used, and it would be better to obtain seed from abroad as far as possible.

If the supplying with *Forastero* be done gradually so that the trees of this variety remain mixed with trees of the old red kind, the pods and seeds produced on the former will usually be found to show more or less of the *Criollo* character in colour, breaks, &c. This is due to the *Criollo* flowers being carried to the flowers of the *Forastero* trees by insects, &c.

INFORMATION DESIRED.

We shall be grateful to planters of cacao for any information relating to the disease; its prevalence, the time of its appearance, whether it attacks young trees or *Forastero* trees; its probable causes; any remedial measures tried, and their results, and so on. In making use of such information no names or places will be mentioned without special permission.

JOHN C. WILLIS, Director, Royal Botanic Gardens.
E. ERNEST GREEN, Hon. Government Entomologist.

THE ROYAL BOTANIC GARDENS'
CIRCULAR IN RE—CACAO.

Sept. 9.

DEAR SIR,—It is strange that in the first circular from the experts on the subject of cacao canker (so-called) no attention has been drawn to the beneficial results of using coral-lime and wood-ash. For years soils have been manured with cattle bulk, compost, bone dust, and bone meal, castor, superphosphates, guanos, cottonseed and coconut poonac, and perhaps a little nitrate soda and sulphate ammonia; but in very few instances, if in any, has an adequate quantity of lime been applied. It would be interesting to know what amount of lime has been used the last ten years; but it is pretty certain the quantity per acre would work out absurdly low. A good proportion of cacao lands has been formerly cultivated in coffee, and we may fairly assume that in coffee days there was the same failure in

applying lime and wood-ash, so that we have soils which have been forced to yield all the coffee that could be raised, undergoing the same treatment under cacao, and now we are reaping the consequences.

Mr. Willis and Mr. Green however disarm criticism and invite—assistance and suggestions, and I now venture to call on fallen cacao planters to work together to find out what is really best, under varying circumstances, in the way of prevention and cure.

Undoubtedly in some soils castor and bones help trees to throw off the attack, and in some cases the use of McDougall's wash—sulphur and tar,—after shaving off the affected bark, has prolonged the life of trees, enabling them also to go on cropping.

In tea we find "*Symplocos obtusa*" (the Singalese Bōmbu) very fatal to plants over a year old, i.e. after the stem is killed or uprooted and the roots left in the soil have begun to rot. They get covered with fungus which spreads, and attacks the surrounding tea roots in a heartrending fashion. It is very possible the thinning out of shade in cacao has a corresponding effect, and here again the digging in of freshly burnt coral lime is useful.

Mr. Willis deserves the thanks of planters for initiating these R. B. Gardens' circulars, and Mr. Green for his enthusiasm in the cause. Our part now is to assist them as far as lies in our power by taking the trouble to use the means recommended, carefully observing and reporting results.

T. KOKO.

P.S.—Cacao is thoroughly worth persevering with, and unless one is very much mistaken, consumption will largely increase and prices improve.

PLANTING NOTES.

FACTORY BULKING.—We specially direct the attention of our Ceylon tea planters to the advice which Messrs. W. Moran & Co. of Calcutta give to Indian planters (in their Report quoted on another page) as to the importance of careful bulking in the factory. More than ever does this require to be attended to.

COCONUTS AND COPRA.—While the price of coconuts is given as R35 per 1,000 in or near Colombo, it is R30 for selected nuts at Kurunegala and beyond, and only R27 on estates beyond Chilaw. The question is, therefore, asked as to whether it would not pay better to convert nuts on remote estates into copra than sell at R27? What do planters with experience of both courses, say to this?

PROCEEDINGS OF THE AGRI-HORTICULTURAL SOCIETY OF MADRAS.—April-June, 1897—have reached us. Here are a few paragraphs:—

Acacia auriculiformis of North Australia.—A young tree of the above fruited for the first time last Dec. It was planted in October, 1894, and is now 25 feet in height with a girth of 15 inches at three feet from the ground, this is a favourable growth as the generality of Australian plants do not take kindly to our climate. A small quantity of the seed has been saved and will be distributed to members asking for it.

Paddy seed to Colombo.—Read letter from the Superintendent, School of Agriculture, Colombo, dated 6th April, 1897, thanking for the two varieties of paddy sent by us at his request in March last, and promising to send shortly some seeds of *Milletia* sp. which makes a pretty flowering tree for parks or roadsides.

Sorghum seed for Colombo.—Read letter from the Superintendent, School of Agriculture, Colombo, 20th May, forwarding a packet of seed of *Milletia* sp. and asking if we could send him some Sorghum seed.

CORK WASTE.—Mr. T. Christy gives us some curious information on another page in reference to this product and he asks for hints as to further uses, from Ceylon. Meantime we should like to know if the cork tree, *Quercus suber* could not be grown in the drier parts of the island?

A TEA FACTORY—on the uttermost borders of Uva and amidst palm trees, is the description given in a chatty letter on page 278 of the Factory just erected for Walton Estate, Moneragala, by Messrs. Walker & Greig. This indicates both planting and engineering enterprise of no ordinary type and of itself ought to hurry on the new road and bridges to enable the tea to get to the Railway.

PLANTAINS GALORE.—The Demerara *Argosy* reports a bunch of bananas in British Guiana that weighed, with the stem, 135 pounds. It was the Chinese variety known as *Musa Cavendishii*, similar to the same variety raised here for export. This monster bunch had ten "hands," with a total of 192 bananas or "figs." The largest hand weighed twenty pounds and the bunch filled a barrel. Such large bunches are not desirable for export, as they are so unwieldy in handling.

THE FLORIDA PINEAPPLE—says an American paper—has established the standard of excellence. Nowhere else in the world is better fruit produced, and nowhere else do influences combine to produce more excellent fruit. The climate, soil and methods are all perfectly adapted. Add to this, quick transit, which will permit the fruit to nearly ripen perfectly in the sunshine before shipment, and one can begin to account for the lack of core, the tender pulp, the delightful bouquet, and the delicious flavor of the Florida pine, grown in a territory less than 200 miles long by not more than 25 miles wide.

"THE AGRICULTURAL GAZETTE" of New South Wales, July 1897. Contents:—Useful Australian Plants, J. H. Maiden; No. 39—A Red Box (*Eucalyptus Bosistoana*, F. v. M.); No. 40—Comet-grass (*Perotis rava*, R. Br.); Botanical Notes—A Fodder Plant for the arid interior (*Portulacaria Afra*, Jacq.), the Alleged Poisonous Nature of Sorghum, Peppercree Oil; The Sheep Fluke (Part I), N. A. Cobb; Explanatory Note on the Analysis of Fertilizers, F. B. Guthrie; Separated Milk as a Food for Calves, M. A. O'Callaghan; Influence of Bees on Crops, A. Gale; Poultry Food, J. J. McCue; Winter Dressing against Black Spot, M. Bluono; Orchard Notes, Geo. Waters; Practical Vegetable and Flower Growing, W. S. Campbell; General Notes; Replies to Correspondents; Agricultural Societies' Shows; Label for Specimens.

LIBERIAN COFFEE, &c. IN THE STRAITS.—A recent visitor to the Straits from Ceylon writes:—"I had a most enjoyable trip," but was too much rushed. There was no doubt that Liberian coffee has found its habitat in the Straits, where it grows most luxuriantly, but this terrible fall in price from \$44 to \$25 per picul is very alarming to those interested. I cannot help thinking, though, that much might be done to improve the sample by more careful drying and by picking and sizing it, like on Ceylon plantations; the bean has a most excellent flavor, and one cannot detect it from "Arabica" when carefully made and roasted. Kuala Lumpur is one of the prettiest towns I have ever seen, most excellent public buildings and well kept park and surroundings, in fact, one of the most striking effects in the Straits and more especially in Singapore is the neat and trim appearance of the compounds, frequently some acres in extent, surrounding the bungalows. Colombo residents might take a hint with much profit.

COCONUTS AND COPRA.—Certainly, writes a correspondent, the more distant districts should send their copra to market, and not their nuts. The weight of the kernel alone is reduced by one-half by drying; add to that the cost of transport of the shell and the water which are thrown away; and you will see how carriage tells.

CACAO DISEASE AND THE R. B. GARDENS' CIRCULAR.—We call attention to the letter of a practical cacao planter on this subject. It is quite evident that cacao disease is far easier to grapple with than leaf disease or bug in coffee, if only *systematic* care is exercised and careful observation made. Separate cacao trees can be treated in detail, and reliable results arrived at, when there are only 300 to the acre—far more so than was the case with coffee Arabica with 1,200 bushes to the acre. Our correspondent advocates the use of lime and wood ashes for the benefit of trees affected: the experiment is well worth trying.

“ROYAL BOTANIC GARDENS' CIRCULARS.”—We call attention to the letter of the Director on this subject, to his introductory notice and to the first of the series of periodical Circulars, all of which we reproduce in full today and welcome with much pleasure. Such periodical deliverances on certain products cannot fail to be useful, and for our own part, as reproduced regularly in our monthly *Tropical Agriculturist*, they cannot fail to increase its interest and usefulness especially to readers in other tropical Dependencies. The discussions sure to arise in the daily press, out of certain of the Circulars as time rolls on, will also be of service when recorded simultaneously in our periodical. In the present case—the circular upon the cacao disease and suggested remedies—there is not much to be said, as the matter has recently been very exhaustively treated in our columns. But we notice that Messrs. Willis and Green are not very hopeful about the old Criollo cacao and strongly recommend all further planting to be with Forastero.

BRITISH CENTRAL AFRICA.—Mr. John M. Moir, one of the oldest and leading coffee planters in Nyasaland, was to leave Edinburgh on 28th August for B. C. Africa. Mr. Moir sends us an advance copy of his paper for,—

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE. Toronto, 1897.—The Climatology of Africa.—Sixth Report of a Committee, consisting of Mr. E. G. Ravenstein (Chairman), Sir John Kirk, Mr. G. J. Symons, Dr. H. R. Mill, and Mr. H. N. Dickson (Secretary). (Drawn up by the Chairman.)

In the present report we are able to publish abstracts of two years' observations made by our old and valued correspondent, Mr. J. M. Moir, at Lauderdale. Mr. Moir is, after a holiday at home, about to return to Nyasaland; but his work has been continued during his absence by Mr. Thomson. We are also enabled, through the courtesy of Mr. A. Sharpe, to publish rainfall observations for ten stations. Earlier unpublished observations for Livingstonia have been added from the note-book of the late Mr. Stewart.

RAINFALL IN NYASALAND—YEAR 1896.

	Inches.
Chirono	34.39
Chikwawa	28.78
Cholo (Nyamtetu Estate) ..	51.26—81 days
Mandala (Biantyre) ..	52.00
Zomba (Residency) ..	63.34
Mlanje—Lauderdale ..	108.15
Nyasaland Coffee Co. ..	78.54
Fort Johnston—Fort ..	42.20
African Lakes Co. ..	45.74
Likoma (Univ. Miss.) ..	50.58
Bandawe (Livingstonia Mission)	92.59—126 days

COTTON.—The experiment made with seeds of the best kind of Egyptian cotton in the Horticultural Gardens, Lucknow, gives promise of some success. The plants are profusely covered with blossom, and it is hoped that they will give a good deal of cotton.—*Pioneer*, Sept. 11.

FISH GUANO.—A Ceylon reader writes us from Kandy that Fish Guano has been tried on tea with very poor results. The favourite fertilizer employed is nitrate of soda. A comparison between the two is of course impossible without the fullest data, but we cannot help thinking that the guano has not been given a fair trial. We hear it is a new but great favourite with coffee planters in South India.—*Planting Opinions*.

THE “INDIAN FORESTER,” edited by J. W. Oliver, Conservator of Forests, and Director of the Forest School, Dehra Dun, August 1897.—Contents: Original Articles and Translations—The Export Works in the Bamsu Forest (illustrated) by G. E. McA. M. Correspondence—Irregularity in the Growth of Teak, letter from S. C.; The number of acres in a Cape Morgen, letter from A. W. Heywood. Reviews—Forest Administration in the Northern and Central Circle of Bombay during 1895-96. Extracts, Notes and Queries. Timber and Produce Trade. Extracts from Official Gazettes. Appendix Series of the Indian Forester. Reports by E. E. Fernandez, Esq. (Report of Pine in Germany and Switzerland), Consr. of Forests, Part III.

TAPIOCA AS A FOOD CROP.—The *Englishman* remarks that a good deal of correspondence has been taking place on the subject of the introduction into India of the Manioe or Mandioca (Tapioca) plants of South America as an alternative food-crop in times of prolonged drought and famine. It appears that the proposal emanated from Dr. Halliday Gunning, who has resided for a long time in Brazil, and is of opinion that the plant could be used as an alternative food when the rice-crop failed in rice-eating districts. It is pointed out that tapioca is already regularly cultivated in the Dinajpur, Raugpur, Bogra, and Jalpaiguri districts of Bengal. The yield per acre is very large. In most parts of India, however, the people have a prejudice against eating the root, and it is grown merely as a hedge plant. Any attempt, therefore, to introduce the plant generally as an alternative for rice would probably fail, though its cultivation might be encouraged in Northern Bengal, where the people are accustomed to regard it in the light of a foodstuff.

PRONUNCIATION: “COCAINE” (8th S. xi 485).—The note referred to is in several particulars somewhat misleading to the *simplicitas laicorum*. What is meant by “words of this formation” I do not quite understand, but there are many words, apparently formed on the same principle as those referred to, in which the termination *ine* does not denote an alkaloid, as, for example, iodine, bromine, glycerine, chlorine, crocine, and carmine. Nor is it quite correct to say that an alkaloid is the active principle of a thing. Many plants yield half a dozen alkaloids, none of which can properly be said to be the active principle of the plant. Opium, for instance, yields, besides morphine, papaverine, thebaine, codeine, narcotine, narceine, and probably several more, each of which has properties of its own, none of which has precisely the same value as any other. There are alkaloids, too, which occur in more than one plant (caffeine, for instance, occurs in both tea and coffee), and there are animal alkaloids, and artificial alkaloids almost without end, to which your correspondent's description would not apply.—C. C. B.—*Notes and Queries*, July 10.

THE TEA TRADE OF THE
FAR EAST:
SOMETHING FOR THE "COMMITTEE
OF THIRTY" TO PONDER OVER:

AN INCREASE, RATHER THAN DECREASE, IN TOTAL
TEA EXPORTS FROM CHINA, JAPAN, AND FORMOSA;
LARGE TOTAL CONSUMPTION OF FAR EAST TEAS
IN RUSSIA AND AMERICA.

The friends of China tea who bemoan the falling-off in exports to the United Kingdom and Australasia, take good care to avoid all reference to the development of the trade in other directions. It is only when we get all the figures brought together that we are able to see that in reality the China tea-growers have not suffered even now, any diminution whatever in the demand for their produce. The confusion arises from the British merchants and Press in China taking little or no cognizance of the trade in "brick tea" via Kiachta to Russia, which has enormously developed in the past 25 years, nor do they even give returns of the "leaf teas sent via the Han River and Fanching," which do not come under the cognizance of the Foreign Customs. Then, again, another element of confusion of late is that the Formosan export of tea is now being connected with Japan, whereas it was formerly given with the figures for China tea. The only way, therefore, to get a fair comparison between the past and present export trade in China and Japan teas, is to put the whole together as we attempt to do in the following statement:—

		EXPORTS OF LEAF TEAS.	
From	To	1871.	1896.
China	U. K. .. lb.	138,915,733	29,254,533
Do.	U. S. .. "	39,806,533	30,146,000
Do.	Russia .. "	4,277,333	45,179,066
Do.	Australasia .. "	12,269,200	6,258,800
Do.	Sundry places via Hongkong ..	17,511,601	40,575,068
Total (Leaf Tea) ..		212,780,400	151,413,467
Do.	via Fanching to Russia .. "	12,149,600	10,439,600*
		BRICK TEA.	
Do.	Russia .. lb.	11,172,000	76,949,200†
Total for China proper ..		236,102,000	238,802,267
Japan and Formosa to America .. "		18,750,000	62,064,000
Total Far East Teas ..		254,852,000	300,876,267
British-grown Teas ..		15,351,600	215,405,000
		lb. 270,203,600	516,381,267

Here, then at a glance, it can be seen that the China tea-growers so far from exporting less tea in the 25 years, have actually delivered 2,700,000 lb. more in 1896 than in 1871, and that Russia has fully made up to them for the less demand from the rest of Europe, America and Australasia. Then we have the export trade in "Japan and Formosa teas" developing from 18½ million lb. in 1871 to 62,064,254 lb. in 1896.

Let us now consider what the Russian and American markets still continue to take of the tea produce of the Far East,—of China, Formosa, and Japan. Here are the figures for

TEA IMPORTS INTO RUSSIA.

	1871.	1896.
	lb.	lb.
China: Congou and green
Tea via Odessa	1,984,000	23,293,333*
Do. " Northern Ports	2,293,333	21,893,733
Do. Leaf Tea via Fanching	12,149,600	10,439,600
Do. Brick Tea via Kiachta	11,772,000	76,949,200†
Total..	27,598,933	132,567,866

Here we have an enormous development of the Russian tea trade in the 25 years, and the fact should be realized that if we could only get the Russians to use Indian and Ceylon teas, our increased production would be required for a good many years to come. So with America if we put all the figures together thus,—

	1871.	1896.
	lb.	lb.
China (Leaf Teas)	.. 39,806,533	30,146,000
Japan and Formosa	.. 18,750,000	62,064,000
	58,556,533	92,210,000

Here, again, we have a large margin to go on in the total of 92½ million lb. of Far East Teas consumed in America. Taking Russia and the United States together, we face a total consumption of 224,777,866 lb. of China, Formosa, and Japan teas, and how to supplant this by Ceylon and Indian teas is the great problem of the day for the tea planters in both countries,—for the Ceylon "Thirty Committee" and for the "Pea Associations" in Calcutta and London. The campaign has already gone on for several years and something more than a foothold has now been gained in both countries. May we see the introduction of our pure wholesome teas into Russia and North America, henceforward increase not at an arithmetical, but at a geometrical rate of progress, and so find our export to these countries doubling every year, until a victory is attained as complete as that already achieved in the United Kingdom and Australasia.

COFFEE, NUTMEGS, RAMIE AND COCO-
NUTS AT THE STRAITS.

FROM REPORT BY THE ACTING DISTRICT MAGISTRATE, (A. W. JUST) MATANG, FOR JULY.

On the 29th July I went by launch to Kampong Dew, and stayed the night at Yam Seng estate. The next morning Mr. Waddell Boyd took me over Selinsing estate. I suppose this is the first time Selinsing estate has been heard of, and certainly it has sprung into recognition very rapidly, and gives already most hopeful promise. It lies a little back from the Kampong Dew road, on both sides of the river, so that from the road nothing of it can be seen, but what it loses in lack of road frontage it gains in having a long river frontage, which will be most useful for the future of the estate the block that lies to the north of the river Sapetang will be twice the size of the block to the south.

The land on the north of the river, a block of 420 acres, is the part of the estate at present being opened up, and is of the very best quality: 130 acres are already felled and cleared ready for planting. The nurseries consist of—70,000 coffee plants, put in in April, now four to six inches up out of the ground; 40,000 coffee seeds, not yet above ground; 8,000 nutmeg plants, planted at the same time as the coffee, in April, and now well up; 2,000 nutmeg seeds, not yet up (of the nutmeg plants Mr. Waddell Boyd is particularly proud); ramie—this is not in large quantities but the quality seems good; 3,000 coconuts.

* Varies greatly year by year: 1879 = 193,733 lb. 1895 = 1,799,600.

† Including 2,717,733 lb. via Odessa.

* Including 631,733 lb. green tea (Hysons) shipped to Batoum.

† including 2,717,733 lb. via Odessa.

PLANTING IN REUNION :
SUGAR, VANILLA, COFFEE, &C.

(From Report by Consul Bennett.)

There still remains, however, plenty of land fit for cultivation besides the sugar belt running round the island, and up to about 1,500 ft. on the slopes. The upland plains of Salazie, Pilaos, Plaine des Cafres, Plaine des Chicots, and Dos d'Ane, among others situated at from 3,000 to 5,000ft., are all cultivable, and, except the Plaine des Chicots, more or less cultivated, but from 5,000ft. upwards the soil is practically non-existent, and cultivation is impossible.

SUGAR AND VANILLA.—The Reunion sugar culture has been fully explained in my report above referred to, and calls for no further remark, except to observe that the fall in the price of sugar and the beet competition have been felt almost as acutely in Reunion, in spite of Protection, as in the British West India colonies. A distinction, however, must be drawn between planters and millowners. In spite of hard times, millowners have been able to offer to planters prices for canes brought to the mill to be crushed which have given fair profit to the planter. The better the mill the better the sugar product, and, therefore, if the planter elects to be paid in sugar, the bigger profit for the planter who chooses the best mill available. It is the millowner who has chiefly felt the pinch. Centralisation of mill has long been recommended, and under given circumstances works well. Decentralisation, *i.e.*, division of labour, would perhaps, work better, the millowner striking to his trade as miller and the planter to his as planter, mutual contracts existing between millowner and planter as to lands to be cultivated and the labour to be supplied on more or less the lines of the Queensland Sugar Acts. But Reunion would be in a far worse plight today than she actually is if she had depended entirely upon sugar. It is hardly too much to say that her planters, or many of them, have been saved from ruin by having a second string to their bow. Many a deficit on sugar has been covered by a handsome profit on vanilla, backed up by sales of manioc, coffee, tobacco, perfumes, cloves, and market garden produce. The largest of all these secondary products is undoubtedly vanilla. There is hardly a sugar estate in the island which has not more or less land under vanilla varying naturally in extent according to the nature of the locality. On the other hand, in certain districts are to be found large planters who cultivate nothing but vanilla, and as regards the quarters of Ste. Rose, St. Philippe, and St. Joseph, it is no exaggeration to say that the mainstay of the people is vanilla. The yards and courts and little plots of ground round the huts are covered with the vanilla creepers. When the pods are ripe they are sold green to a neighbouring merchant, realising quite a small fortune for the grower. The only drawback to this crop is that it gives rise to an immense amount of theft and dishonesty. The pods are stolen by night, and in spite of stringent laws are passed from hand to hand, and finally lost for ever to the grower. Many considerable fortunes are known to have been accumulated by illicit vanilla buyers, but the detection of the culprit is almost as difficult as that of a diamond thief at the mines.

SELF-SUPPORTING ESTATES.—In conclusion, Consul Bennett writes: The main industry will be seen to be sugar; coffee and vanilla and tapioca forming the only serious aids to counteract low prices and losses on sugar. But the fact must not be overlooked that large Indian corn, bean and pea crops are grown upon all estates, and that market garden produce is largely cropped either for family consumption, for supply to neighbouring towns, or for export to Mauritius and Madagascar. With the exception of flour, beef, and rice, all of which are imported, a well-managed Reunion estate is practically self-supporting as regards men and beasts and fuel for the mill, for no coal is used in the mill furnaces; and according to its vicinity to town or railway can make a considerable yearly income by the sale of market pro-

duce, &c. Continuous efforts are made to substitute Indian corn, peas, beans, lentils, and mandioca for imported rice, and one of the results of the plague at Bombay has been to very largely aid in forcing the inhabitants to look to native products in view of the great rise in the price of rice. As a rule, however, the market gardener is sadly hampered by want of means of communication; he can grow beautiful produce, but before he can reach the consumer freight has eaten up the profits. Neither are export duties charged at the ports favourable to the development of a trade with foreign or neighbouring countries. Something has been done to save the island from depending solely on sugar, but there is room for improvement. Reunion ought to grow all its own corn on its fertile upland plains. Horse and cattle rearing could be profitably extended, and sheep-raising on a smaller scale, with the by-products of soap, candles, and manures.

PLANTING &C. AT THE STRAITS.

The Acting District Officer, Ulu Langat (Mr. O. F. Stonor), Reports for July:—

Advantage has been taken of the moderately dry weather of the past six weeks to burn off numerous clearings throughout the district, many with but average success, owing to the enforced delay during the recent prolonged rainy season, and a consequent anxiety to take advantage of the earliest opportunity.

Padi, at the time of writing, is being transplanted from the nurseries, to the fields and the people are looking forward to a prosperous year, should present prices be maintained.

That energetic miner planter, Mr. Goh Ah Ngee, has applied for a grant in respect of 29 adjoining customary holdings near Semenyih (measuring altogether some 550 acres) which have recently been transferred to his name. I have referred in former reports to the promising work being done on this estate, which is, for the most part, worked by Christian Chinese.

Amongst native coffee growers I am glad to notice signs of an increasing belief in the practice of "topping" the trees—a practice which is, I believe, generally advocated by European planters. The condition of many of the older Malay gardens is certainly no advertisement to the contrary, though the systematic cultivation of lalang, and various sorts of weeds, has probably more to do with the result achieved. Remonstrance is invariably met with the plea of want of labour, the proprietor preferring to concentrate his energies on crops which yield a quick return, and leave the coffee to take its chance.

Good progress is being shown in the construction of the Sungei Cheow Road bridge over the Langat River. To enable the metalling of the road to be proceeded with forthwith, and to provide better means of access to the temporary railway station, it has been decided to construct a connecting road between the present foot-bridge and the Sungei Cheow Road, of sufficient width to carry a light line for trucks. Work is now in progress.

The opening of the railway extension is expected to take place during August, rails have been laid, at the time of writing, as far as the temporary station.

I am glad to notice a steam roller at work on the Cheras Road, the surface of which has long been a source of supreme discomfort to travellers.—*Selangor Government Gazette*, Aug. 27.

The District Officer, Ulu Selangor (Mr. R. C. Grey), Reports:—On the evening of July 27th there was a slight disturbance in Kuala Kubu village. Some thirty or forty Chinamen, armed with sticks, effected an entrance to a brothel and committed an assault on one of the inmates, against whom they had a grudge. On the police interfering some of them were beaten also. The following morning twenty-five mining coolies were charged before me with riot and four men convicted. Serjeant-Major Mat deserves great credit for the prompt action he

took in the matter. Although all the rioters had at first got away, he had a shrewd suspicion of the kongsi to which they belonged, and proceeding there very early the next morning with a body of police, he arrested all the inmates. Though only four could be convicted there is little doubt that the whole party took part in the disturbance. Small fights in the village have been very frequent of late and it is to be hoped that this will have some effect in stopping them.

On the 28th I went with Mr. Edmonds to Kuang, where we met several Malay padi-planters, under the Penghulu, Raja Isa, who are anxious to start padi planting on a large scale there and are desirous of asking the Government to help them to dam up the Sungei Kuang and divert it into some hundreds of acres of low-lying land at Kuang. I have already reported on this subject.

On the 29th, early in the morning, we walked over Mr. Pasqual's coffee estate with him. Mr. Pasqual has done very good work on the estate in a very short time, but he has been put to much inconvenience owing to the delay in the survey of his estate.—*Selangor Government Gazette*, Aug. 27th.

JAVA CINCHONA—ROCK-BOTTOM REACHED.

The annual report of the Society of the Java Cinchona Cultivating Company, "Garoot," of Amsterdam, states that the year 1896 has resulted in a net loss of 582 florins (about 50%), which, added to the loss of the previous year, makes a total loss since 1894, of 16,351 florins. The total expenses during the year amounted to 16,269 florins, and the revenue of the 54,690 kilos. of bark, sold at auction in Amsterdam during the year to 15,687 florins. The prospects are considered fairly satisfactory, but the directors propose to harvest only so much bark as is absolutely necessary, in order to allow their plantations to mature.—*Chemist and Druggist*.

B. C. AFRICA.

(*Central African Planter*, July 10.)

Mr. Israel is to be congratulated on having obtained a maiden crop of 20 tons of coffee from an acreage of about 48 acres. This output is an encouraging prospect for the future industry of Coffee in B. C. A.

We understand that Mr. Crabbe will not return to the management of the Nyasaland Coffee Company's estates. Mr. Moggridge has been appointed Manager. The Company is to clear 150 acres this season, which will make a total of 400 acres odd and this having been undertaken in two years shows there is no lack of labour.

Several other clearings are being opened in the Mlanje district which will add a few more hundred acres to the area now under cultivation. Mr. Boyd has assumed charge of Mr. Bradshaw's Estates.

"THE AGRICULTURAL LEDGER."

1897—No. 5 is the value of Silt as a manure. A note on some experiments which have been made to test the value of Canal Silt. By Dr. J. W. Leather, Agricultural Chemist to the Government of India.

1897—No. 6 is the tinctorial properties of Kaiphal Bark and an analysis of the colouring principle. By professor John James Hummel and Mr. Arthur George Perkin. With an introduction by Mr. David Hooper.

1897—No. 7. Reclamation of Reh or Usar Land. Note by Dr. J. W. Leather, Agricultural Chemist to the Government of India, on certain experiments which have been carried out for that purpose.

A TRIP ON THE BOUNDARIES OF UVA.

Having passed Buttala where there is a Dispensary which distributes the much-needed and beneficial quinine,—we reached

KUMBUKANA

where there is another resthouse. Not the usual type but an "upstairs" bungalow." Just in front the hill of Moneragala towers up, and looked quite imposing after the long level stretch of feverish country we had come through. At its base near the village of Mupane Messrs. Walker and Greig, Haputale, are building a large

TEA FACTORY

for Walton Estate. It is near the cart-road and the tea is to be sent down from the hill above, by the usual method of wire-shoots.

This picturesque factory, situated in the midst of palm-trees, was only begun in the end of May and was to be completed by the 1st September. When one considers the tremendous difficulty of getting heavy materials and machinery over such a road, the feverish district, and many other obstacles, it says a great deal for the enterprise of the firm, that their engineer has been able to do it in such a short space of time. It seems to be the beginning of opening up a new district, and when the two rivers between these and Wellaya are bridged, there will be a passable outlet for the produce—right up to Haputale station.

ECHOES OF SCIENCE.

Catching Insects by Electricity.—In these long summer days thousands of amateur naturalists are enjoying the fresh air of the woods and fields in hunting for specimens of insects, but probably few are aware that the electric light can render them a great service in this respect. Light is a fascinating lure to insects, fish, and wild creatures. Entomology has lately utilised this fascinating effect of light on insects, by employing it to draw them into a pond, net or trap. An electric glow-lamp of three or four candle-power, fed by a small battery such as cyclists use for lighting their machines, is fixed to the trap, which is lowered into the water. The current is switched on, and the light shines out. Ere long, insects, frogs, newts, and fishes gather round the strange light, and are easily caught.—*Public Opinion*.

ABYSSINIAN COFFEE.

It is interesting to note in Mr. Rennell Rodd's report on the trade of Abyssinia, just issued, he refers to—as if the matter were of no importance—to the fact coffee grown there is largely consigned to Mocha, whence it is exported as the genuine product of the place. It matters little, perhaps, now that Mocha figures so lightly in our imports, but it would have grievously affected Dr. Johnson and the wits who assembled in the first coffee-houses of the City to learn that the "heavenly decoction" came not from Arabia Felix but from the Dervish country. And yet coffee which is indigenous to Abyssinia, takes its name from Kaffa, where from time immemorial it has been cultivated where now the greater part of the product of the country is raised. Were it not for the peculiar customs of the country which retard commerce instead of fostering it, we should get a quantity from King Menelik's dominions, for the finest berries in the world are grown there.—*Grocers' Journal*, Aug. 21.

COFFEE PLANTING IN NEW SOUTH WALES.—It is rather curious that Reuter should telegraph from London this piece of news of the premier Australasian colony encouraging coffee planting. Our information goes to show that Northern Queensland offers a far better field for coffee than even the rich lands in the N.-E. portion of N. S. Wales; for one thing we should fear frost in the latter.

"HOW TO ECONOMISE THE AVAILABLE LABOUR SUPPLY ON OUR TEA PLANTATIONS."

REVIEW OF LETTERS NOS. X. TO XVII.

The last eight letters must now claim our attention; and they are full of variety and interest. "L" from the Northern Districts, is able through experience to anticipate the doubt which "M" from Matale North gives expression to later on in regard to the suitability of wire shoots for the transport of produce; and the directness and confidence with which "L" asserts that he has "worked shoots for many years" and "for all purposes," illustrate one of the many advantages of the interchange of ideas for which we have arranged through our circular. *Experientia docet*; and here is a writer who has used shoots "for sending firewood, tea leaf in coir bags, jungle soil for manure in gunnies etc., etc."; and all he stipulates for is that there should be "lots of packing" at the delivery end, so that the leaf may not be damaged, as it would be, if the impact were against the tree or rock to which the shoot is attached. The hesitancy of the unbeliever,—that is of the inexperienced,—should vanish before such testimony, supported as it is by "A" from a medium district, who has seen shoots used in the great saving of both labour and time on extensive and steep estates. In one case, he says there was a saving of five miles in transport through three shoots which took the leaf to the store in 20 minutes. What this means in coolies available for other work and exemption from grumbling, only those who have experience of shoot and coolie labour can appreciate. "R" from Uva tells the same story; also "T" from Medium District and "T" from Northern District three-fourths of whose leaf is brought in by means of shoots; while "G" in his lengthy and instructive communication, though having no personal experience of shoots, affirms that their use is capable of "very great extension and improvement." Experience of aerial tramways, too, confirms the general feeling in their favour; and most of our correspondents doubtless regard them in the light of improved and more scientific shoots; but there appears to be a consensus of opinion that the initial cost of rail tramways is prohibitory, and places them beyond the reach of any but the most extensive estates, and even in their case, if they can be easily roaded, light bullock-carts will be as serviceable while saving the heavy original outlay of a tramway.

On the question of lighter and less expensive Weeding, the present batch of letters shows, with one exception, the same conservatism as the preceding batch, and even some little impatience that the question should be revived. "Surely this question has been threshed over long ago" protests "L," who would have "a clean estate, or none at all"; though looking to the great deficiency of humus in our clayey soils, he would prefer to grow nitrogenous weeds—or say the Californian Cow Pea—and fork them in, if the labour were forthcoming. From Uva we learn that experiments have told against less frequent weeding, leading to the ultimate use of mamoties with disastrous results; while in Dimbula the retention of mosses and ferns threw coffee back

rapidly and seriously. "A" similarly sticks to clean weeding, both for its own sake, and as helping to satisfy the contractor-kangany; while "M," who holds the same opinion, advocates the more general growth of shade as a means of keeping-off weeds and preventing wash. With that advantage, we fancy, must go the drawback of a falling-off of flush which needs sunlight to bring it out on hardening branches. The answer of "R" from Uva seems rather contradictory as he holds weeding overdone, while declaring that "in Ceylon we must have practically no weeds" and that "our present system is good enough, it scraping is fought against"; but "T" believes unequivocally in keeping an estate "thoroughly clean," though mosses do not injure tea on well-drained land. "T" from a northern district, on the other hand, would not leave any mosses, as they would form seed beds for other weeds, and in damp climates themselves cloke up the trees and produce unhealthy barks. Against this body of opinion, we have a very decided dictum from "G" in a mid-district, who does not content himself with merely affirming that "weeding has been and is being overdone"; but offers reasons in support of his view which we commend to the earnest attention of our readers, and which we should like to see discussed and answered by the advocates of clean weeding at any expense. "G" points to the bare red soil on our hillsides, destitute of all humus and affording no lodgement for fresh accumulations of leaf-mould, as evidence of injudicious weeding which has not only cost vast sums of money which might have been saved, but has positively worked to the detriment of the land. Coffee found itself unable to survive such treatment, but tea as a deeper feeder is less dependent on surface soil. Yet, it must benefit by the conservation of humus; and what "G" suggests seems very simple. He admits the impracticability of hoeing in the weeds, once in two or three months, as in India, on steep land, but would have a system of water-holes between every four trees, into which the weeds at every bi-monthly hand weeding—by which, we suppose, is meant the weeding once in two months and not twice a month—should be thrown. This would do more than give back to the soil the constituents which they had taken from it, by enriching it with the added nitrogen they have drawn from the atmosphere. At the same time, it is pointed out that there are mosses and other small plants which assist in the formation and retention of humus, and also serve to minimise wash; and if such mosses and plants are selected with discretion, even the necessity for artificial manuring might be obviated. These mosses would be auxiliaries to the leguminous plants which have the special quality of absorbing nitrogen, if indeed they do not take their place to some extent, and they might also find a place in the water-hole, where the steepness of the land forbids their being hoed in. The supplementary information which our correspondent supplies on the weed which he thinks it would be well to encourage, to prevent wash and loss of soil—*Pilea microphylla*—is specially interesting, as is indeed the whole letter with its happy combination of the practical and the scientific. Our own inclination, as indeed our question in a manner suggests, is to the view that weeding is rather overdone; and although numbers have, so far, been against us, we are content with the measure of support which "G" affords with his well-reasoned advocacy of selective weeding,

On drainage, too, there is much useful information in the letters before us, all which agree in condemning deep drains far apart, and in giving preference to the more modern system of shallower drains at more frequent intervals. "G" certifies to the help he has obtained from cuscus in preventing wash; and he therein confirms the testimony of the low-country planter in the first batch of letters we last reviewed. On reference to the same planter we learn that he has found suitable permanent barriers in logs of wood or blocks of stone buried in the drain at intervals which would arrest soil and gradually clear the water of matter in suspension as it approaches the wells he provides at more distant intervals. But what answers for tolerably level land may not do for steep fields. On the questions of boutiques and taverns there is considerable diversity of opinion, traceable, we fancy, to differing conditions; but vegetable plots for coolies find warm supporters. There is one point to which we would invite special attention—the explanation which we have from Uva of the Arcadian happiness of the Principality. Its freedom from labour troubles is chiefly due to the length of time estates are under the same management. The cooly knows his master!

(Letters Continued.)

NO. XVIII.—LOW-COUNTRY.

- (1) Don't know enough to give any decided opinion.
- (2) No experience in tea, so have had no opportunity of observing.
- (3) Only in exceptional cases I should say.
- (4 and 5) Yes; I have often thought so, but never could think of any weed that might be employed to protect the ground and save wash without being injurious to the tea or coffee. The entrance of grass would have to be carefully guarded against. Mosses etc., would do on high estates, but they would not grow to any extent below 4,000 ft. Some imported plant, of very low growth, would have to be tried. While this system would I believe be beneficial, I doubt its being labour saving.
- (6) No. I am entirely against loosening of soil on even moderately steep land. The loss in soil is infinitely more than the temporary gain by loosening the soil for the roots to have a larger feeding surface.
- (7) While not satisfactory I know of no better to take its place. Some such plan as that you mention of growing *cuscus* above the drains would be advantageous. I have seen bundles of *maana* staked across the hill side, answer well.
- (8) ———
- (9) During the months of heavy flushes a rupee per head might be given to every cooly who worked 24 days in the month. I tried this in the coffee days and it answered very well. So far as my experience extends any cooly who wishes for a plot of ground for a garden could have it; many, however, prefer to pilfer the fruit of the labour of others. I think that those coolies who do make a garden and attend to it are more loath to leave than those who have none.
- (10) I cannot answer this question. If coolies are compelled to buy goods at any particular bazaar, though the goods may be first-class and reasonable in price they will grumble and think they are being imposed upon. They like to traffic where they please.
- (11) I reside in the lowcountry where liquor shops are numerous; but illicit sale of toddy is the worst. It is cheap and a cooly can get drunk for a few cents. It is the source of no end of rows in the lines. The muster of coolies would decidedly be larger if liquor shops were fewer. (Signed) W. J.

NO. XIX.—HIGH DISTRICT.

- (1) No practical experience; have seen them working. Said to damage leaf, but I should not think damage would equal the advantage gained by

the use of the shoot in saving labour. There must be a great advantage, again, to those who use them, in transporting firewood.

(2) Telephones, tavalams, wire tramways, cart roads where none existed before. Carts in the low-country.

(3) Could not easily be worked on steep estates, and would be too expensive on a majority of places.

(4) Emphatically no. Sometimes very underdone.

(5) Decidedly no. The cleaner the better for every thing and everybody concerned.

(6) No. Might be useful on flat land. But rather impracticable on steep.

(7) Where large (18 inches at least) drains are opened, and kept so, very satisfactory. Grevilleas might also assist to prevent wash, and keep up soil; but as a rule any extra growths prevent easy working of the land.

(8) Keeping labour well occupied, preventing loafing in the lines, this will cause the coolies to become more apt, when more work will be done, and so economise those available. Good and suitable tools also assist this end materially—a matter to which sufficient consideration is not always given.

(9) I do not think coolies having gardens matters in the least, one way or the other, to make them more contented. If they intend to stay on a place they will almost always have or make a garden. My experience is that they ask for and require more line room than they did formerly.

(10) I am not favourable to the increasing of boutiques or bazaars on estates as I think they are the next temptation to liquor shops for coolies not to work.

(11) I am not I am happy to say troubled here but I have known of the disadvantages of a liquor shop elsewhere. Many quarrels would be prevented, and much labour to an estate would be gained by their reduction or abolition. In this connection I am afraid more illicit sale of arrack, than is thought, goes on on estates. Y.D.D.

NO. XX.—MID-DISTRICT.

(1) Generally work very satisfactorily, and should be used far more than at present on tea estates, their great cost lies in "Runners" which are very expensive and wear out quickly, surely something more enduring could be provided? cost so long as the runner is lasting could be met. Have not found leaf damaged.

(2) None.

(3) Don't think so.

(4) Certainly not.

(5) No. Anything covering the surface of the soil prevents light and air reaching the feeding roots of the bush, and the plant sickens, even Grevilleas grow better where the surface of the land is kept free from weeds. I have a section of an estate that always gets covered with moss during the South-West monsoon, you would be surprised how the coffee used to, and now the tea improves when this moss is cut away with carandies in the early part of the year.

(6) No.

(7) The best we can do, if labour were always available would be to cut drains at a gradient to take off the water only, and at frequent intervals top dress with the accumulating silt. The sourness from cuscus or grass of any kind is objectionable to any kind of cultivated bushes. The roots also would injure one line of tea the whole length of the drain.

(8) Nil.

(9) On old estates where there is plenty of spare land, gardens are large, but those who cultivate them are generally friends of the kangani and seldom do any other work. The good estate cooly, who kept his little patch of ground and worked it for a few beans, chillies, etc., and never dreamt of its interfering with his ordinary day's work, is a man of the past. The more garden available, the less work there is from a cooly now.

(10) No, the cooly like everybody else prefers going to "London" to buy his provisions, where there is sufficient competition to ensure his getting all he wants at fair market rates, which he does not do in Estate kaddies: these are generally run by kanganyes or their friends who give "tick," with the object of getting the individual cooly more and more into their clutches.

(11) Yes. The fewer liquor shops the better. S.

XXI.—LOWCOUNTRY.

(1.) Where transport of manure and firewood is down-hill there is no question of the utility of shoots. For tea-leaf, wire tramways worked by power at the store will save crushing and damage, and loads can be sent up-hill.

(3.) My experience of tramways is confined to this estate where we have a 2 ft. tram. It saves a deal of labor. Each car fully laden (4,000 lb) is moved by four coolies.

(4.) Yes. I always thought that the system I have read of as applied elsewhere, of cutting down weeds, as the correct and scientific one.

(5.) When I was an up-country planter I always encouraged the growth of mosses and other low forms of vegetation as soil binders.

(6.) Mr. Holloway, shewed me some years ago a field on which he had experimented with green-manuring and it looked very well.

(7.) On Arapolakande, in the Kalutara district, terracing with stones between drains was successfully tried by Mr. J. Newman. Cuscus above drains is good. In the old coffee days I saw from a distance an estate with guinea grass both above roads and drains. Wash was said to be effectually stopped.

(9.) I would suggest that coolies who work 24 days and over a month be paid an increased rate of wages. Gardens are much appreciated.

(10.) We have enough of boutiques down this way and I do not think their multiplication will do much good.

(11.) Liquor shops, licit and illicit, are the curse of the country. Coolies who patronize them do not work steadily and they steal produce. B, W.

XXII.

(Engineer's Opinion.)

(1.) Yes! I have erected many, and they could be much more freely used than at present. If properly erected at an easy gradient (not too steep) they do not damage tea leaf.

(2.) Endless wire rope tramways could be very much more freely used and effect an immense saving in transport.

(3.) Yes! but not on the average estate; but certainly a good many labour-saving appliances.

In my opinion, water power could be much more freely used, especially as regards estates having a small quantity of water and a large fall, where Pelton wheels are applicable; of which I have very considerable experience.

Many estates are now working with a steam engine the whole year round, and water power obtainable for say 8 to 10 months in the year, at very little cost.

Transport of firewood is often very heavy and a job the coolies don't care about.

ENGINEER.

XXIII.—LOW DISTRICT.

(1.) Yes. Where they can be used profitably, they have as a rule been put up. This applies to the transport of firewood, as on few estates can they be used profitably for the transport of leaf. No, not to any great extent.

(2.) None known—tramways.

(3.) Doubtful. Their first cost (I presume at least R1,500—2,000 a mile) would be too great and the amount of traffic relatively too small for the earnings of such

lines to cover interest on capital. This applies to the ordinary estate where the factory is more or less centrally situated.

(4.) No. The soil is too poor to support anything but tea, which is a sufficiently heavy crop in itself. In new clearings especially, the cleaner the ground, the better the growth of the plants. Moss, however, when left does not seem to do harm, but it will only grow on certain spots. What is undoubtedly wanted is some plant that while spreading thickly over the ground and forming a mat would take little or nothing out of the soil. I know of none such.

(5.) No. It might be tried on flat land; but any such experiment on sloping land would through the thorough loosening of the soil only increase the amount of wash.

(7.) Fairly so, but the best means of stopping wash, would be the thorough terracing of new clearings before planting; impracticable on account of expense. I know nothing of the grass mentioned and am afraid unless the rows were planted very close al through the tea, it would be useless.

(8.) I think, in connection with transport of leaf, more use might be made of tavalam bulls for ordinary transport, where the factory is any distance from the work.

(9.) Yes, a cooly is undoubtedly less prone to leave an estate where he has his own patch of garden. Most lines have gardens round them.

(10.) Yes, a very good idea, especially if one or two boutiques were run in connection with or under supervision of the estates, coolies to be allowed to purchase so much per month, amount to be debited them in the Check Roll and paid to boutique-keeper at end of month. Estate to equalize prices, &c.

(11.) No. The curse of the cooly is not the liquor shop *per se*, but the illicit sale of arrack on estates brought either by outsiders or coolies belonging thereto. This is more prevalent than is generally known and is most difficult to detect. K. V.

No. XXIV.—HIGH-MEDIUM DISTRICT.

(1) Yes! No, not at all events to any appreciable extent.

(2) I have seen nothing used in the matter of labor saving appliances other than what has been published.

(3) Where manuring is done to any extent, trams would no doubt, be very serviceable. I have, however, had no experience.

(4) Yes! where scraper or mamoty weeding has to be done it simply loosens the soil for the next rain to wash it into drains, and from thence to ravine or other outlet.

(5) Mosses tend to keep soil together; also, I think to keep ground moist in dry weather.

(6) Cannot venture an opinion.

(7) I have seen, on a small patch, a ledge of tea immediately above roads and drains, and it undoubtedly proved a barrier against soil being washed away.

(9) I am a great believer in leading coolies have a strip of garden ground, for if they ever cultivate it, they take an interest in it, and are loathe to throw it all up at the bidding of their kangany. I believe in distributing vegetable seeds.

(10) Coolies prefer to meet, at some central place for their weekly supplies, as they can then depend on seeing their relations and friends. Boutiques on estates I think, generally lead to illicit sale of arrack, and perhaps for reception of stolen produce.

(11) Liquor shops in the neighbourhood of estates are a perfect curse and generally mean at least ten per cent more loafers about estate lines, than there would otherwise be.

"LUNUGALLA."

No. XXV.—HIGH DISTRICT.

(1) Every tea estate ought to have wire shoots leading to the factory wherever the lay of the land is favourable. The damage they do to tea leaf is practically nil.

(2) Endless ropes, or aerial tramways, for uphill transport in the field, and all machinery in the factories are labour-saving appliances.

(3) On most upcountry estates, I should say the gradients are too steep for ground tramways, but wherever an easy gradient is obtainable they might be very useful.

(4) From long experience, my opinion is that weeding cannot be overdone, provided it is done carefully, with the minimum of scraping of the soil only allowed. Of course, it can be greatly overdone when heavy scrapers and machines are in use.

(5) I do not think any saving of labour can be effected by weeding less frequently, but just the reverse, as if the weeds were left for some months, one weeding would probably cost a great deal more than two or three monthly weedings. As to selected weeding, I am afraid it would be hopeless, as the extra supervision and trouble it would entail would be infinite. The weeders would most certainly leave obnoxious weeds, in the shape of grasses, &c., amongst the ferns and other selected weeds, which in time would lead to no end of trouble and expense. I have personally tried it and found it a failure.

(6) I have never tried any experiments in lupines, &c.

(7) If the estate is handweeded, or practically so, the present system of draining, on our steep hill sides, cannot well be improved upon, if the drains are close enough, say half-a-chain apart, and traced at proper gradients, say 1 in 12 to 1 in 16.

(8) The use of bullock and hand carts as much as possible.

(9) I think the coolies ought to be allowed more space for gardens &c. than they generally have at present. Some Superintendents, in my opinion, are very parsimonious in this direction. All coolies appreciate a good plot of ground however small, and at present I fancy not more than 20% of our labour force have anything of the sort. Those who have not, very often feel the want of this convenience and have to go to the villages, and other places, to buy vegetables &c. instead of having a supply at their doors.

(10) In some districts bazaars are plentiful and in others they are insufficient, but it is almost impossible to get coolies to take their supplies from any one place. They will go miles to get their currystuffs at a fraction less cost than they could get the same articles on, or near to, the estate for an insignificant extra cost.

(11) Not much trouble about liquor shops in this district, but there is no doubt the fewer there are the better, although I think it would scarcely do to abolish them altogether. G.J.R.

NO. XXVI.—LOW DISTRICT.

(1) Wire shoots are in use for firewood and leaf on many estates, but the formation of the land and situation of the factories render them impracticable on many others.

(2) There is no work so hard on coolies or which disgusts them so much as carrying chests of tea. Light narrow hand carts would obviate this very much and ought to be in more general use than they are.

(3) On the majority of estates, no practicable, would pay on very few.

(4) No, but often underdone.

(5) There ought to be little weeding. Clean the land thoroughly to begin with and never allow weeds to get to a length that the soil would be disturbed by taking them out. Mosses should never be disturbed—they grow in wet seasons—and go off when heat and drought set in having served a good purpose while they lasted.

(6) No, nor do I believe it would be advisable in Ceylon where our lands are so steep even though we had the labour, nor do I believe it would return the cost.

(7) The present system, I believe, is as good as we could get but the distance between the drains is often too great; with 16 to 19 chains drains to the acre

according to soil and lay of land, there won't be much wash.

(8) Hand carts for transport of tea, lead, building materials, everything, where practicable will save 30 per cent to 40 per cent in cost and be much easier for the coolies.

(9) Certainly give coolies plenty of garden space; it makes them more at home, and if they barter a pumpkin or a few sweet potatoes for a coconut at the caddis, why not? In the low country it is a wise thing to dot the estate over with jak trees—they will begin to bear at 6 years. Set apart a division for each set of lines to get the fruit and leave out the balance—the Sinhalese will readily take it up.—Estates with plenty of jak trees will never be short of coolies.

(10) Liquor shops—especially illicit—are unmitigated evils in every district and Government Agents and Police Superintendents are powerless to suppress them,—though the places are pointed out to them. They are above detective work themselves; the supposed detectives they send are well entertained and bribed and report “nothing wrong.”

W.M.U.

PICKINGS.

INDIAN INK, says the *Indian Forester*, is made in China as follows:—

SESAMUM (GINGELLY) OR COLZA OIL or oil extracted from the seeds of *Dryandra Cordate*, varnish and pork fat. The lampblack got by burning these is mixed with glue and made into a paste which is beaten on wooden anvils with steel hammers. Generally some musk or camphor is added for the odour, and gold leaves to give a metallic lustre. Two good hammers can prepare 80 pieces each weighing half a pound. The price varies from 2s. or less per lb. to as much as £7 per lb., there being over a dozen different grades. In 1895, about two tons of Indian ink were exported to foreign countries from Shanghai valued at £564, but the best part of the manufactured ink (and the best qualities) are used in China and not exported.

According to the *Agricultural Gazette* of N. S. Wales, “Experiments with

RHEA

have shown that this fibre plant will thrive to perfection in the loose, well-drained, sandy loams of our Northern river districts.” The Government is anxious to encourage the cultivation of the crop on a commercial scale and intends offering a special prize for quantities of the product suitable for export. It is said that numbers of farmers have already arranged to put small areas under Rhea this year.

CEYLON TEA IN AMERICA AND ON THE CONTINENT OF EUROPE.—The “Thirty Committee” have resolved that the Tea Advertising Campaign must be vigorously pressed in America for another year, at least: £12,000 have accordingly been voted for Mr. Wm. Mackenzie to spend during 1898, and attention is to be given to the Western States. For Russia £2,000 have been voted; but we were not told who are to be the Advertising Agents. For the rest of Europe, but more particularly Austria and Hungary, the great tea house of Messrs. Cooper, Cooper & Co., are to be assisted in advertising. What will “Horniman’s” and other rival houses say to this? However, the work of advertising is to go on merrily and that much good may come of it must be the earnest wish of all in Ceylon. We only hope the Indian Tea estate proprietors will do their duty as fully as their Ceylon brethren. If Ceylon expends £12,000 in America, India ought to lay out £16,000 to £18,000; and in same proportion in Russia, &c. If further warning as to the need is required, we would just point to the latest deliverance of the *Investor’s Guardian* quoted on page 283 *et seq.*

TEA IN CALCUTTA ; FACTORY BULKING.

(From *William Moran & Co.'s Market Report.*)

Calcutta, Sept. 1.

FACTORY BULKING.—In a circular dated 23rd August just issued by the Indian Tea Association, the proceedings are reported of a meeting held in London, attended by most of the influential men of the *Indian and Ceylon Tea Trade*. Mr. Peek, the Chairman of the Dealers' Association, said: "The Trade would like to know where the Tea was bulked, but they preferred bulking in the Factory, because Tea got injured by being bulked in London." He further stated with regard to Teas not bulked on the Factory: "That what professed to be a sample of the bulk in some instances, was not what it purported to be, the result being, that the Trade not only had parcels of Tea thrown up by their customers, but often lost an account in consequence." In the face of this very decided opinion in favour of Bulking on the factory, we invite Agents and Managers to give it their attention, no chance should be lost to give Indian Tea every advantage in our power, to further its popularity with the consumer. Owing to the heavy arrivals of our Crop, during the rainy months in London, and the present system which prevails of bulking all Teas, exposure to the damp atmosphere is unavoidable, even under the most careful superintendence, as the bulking rooms, by the Fire Insurance rules, cannot be artificially heated and many fine parcels suffer in consequence and lose their flavour. If Factory bulking can be made really reliable, we think, it will prove a great boon to the Trade.

TEA PLANTING IN ANNAM.

A French paper states that after a long series of efforts and attempts which have been pursued with indomitable patience two Frenchmen have at last succeeded in giving to Annam a new industry in tea planting. It was in 1780 that the first attempt took place without any result; but in 1855 a French missionary residing at Phu-Thuong succeeded with a great deal of energy in getting some tea plantations started, but he was obliged to return to France, and thus the result of his energy was for a time dormant. Another missionary, after the insurrection of 1885, succeeded to some extent in making the population understand the value of tea planting. From that time all the neighbouring villages vied with each other to such an extent that now all the hillocks of Tung-Sen, Kien-Kien, Phu-Hoa, &c., are covered with tea, where formerly nothing but unhealthy shrubs were growing. Subsequently some French merchants came, they rented a few plots, and undertook to propagate by example in practising on their own plantations a well understood pruning, thus making the plants strong and healthy. A mission was sent to China, another to Java and Ceylon. A temporary factory was created in 1895, and today the cause has been so well fought that all the district of Phu-Thuong is devoted to the methodical culture of tea. A large brick and stone factory was constructed at Phu-Thuong at the beginning of this year, where the tea leaves are prepared as at Java and Ceylon, but without the addition of the perfume to which the Chinese have accustomed the Europeans.—*L. and C. Express*, Aug. 27.

PAPAW-JUICE.

A 30lb-case of the concrete juice of the papaw (*Carica Papaya*), shipped from Ceylon, was included in the drug-sales recently. It consisted of small irregular masses of a light brown colour, having an odour somewhat resembling that of Para-rubber. Papaw-juice is obtained by scarification from the unripe fruits, and is generally employed medicinally in countries where the tree is found. The active principle is readily precipitated by the addition of alcohol. Many virtues are attributed to papaw-juice; it is said to have the property of rendering tough meat tender, is used in the treatment of dyspepsia, diphtheria and as an anthelmintic, and is also recommended for eczema. The lot in question was sold at 5s per lb., "subject to approval."—*Chemist and Druggist*, Aug. 28.

TEA SHARES AS AN INVESTMENT:
INDIA AND CEYLON.

In our recent article we tabulated the net revenue receipts for 1896 of nearly one hundred tea-producing Companies of India and Ceylon. These statistics showed that 57 Indian Companies, with an aggregate paid-up capital of £4,730,523, last year earned a net profit of £447,197, equal to 9.45 per cent. and 37 Ceylon Companies, with a capital of £2,531,112, made £272,229, equal to 10.75 per cent. Together, the ninety-four Companies with a paid up share capital of £7,261,635, made £719,426 in net profits, equal to 9.90 per cent. all round. These figures, we remarked at the time, pointed to tea-growing as a very remunerative undertaking, and it being, in our opinion, a sound and well-established industry, we unhesitatingly commended the debenture and preference shares generally as affording opportunities for safe investment. We added, however, that there were circumstances affecting the future of the trade which needed to be carefully considered in estimating the value of the ordinary shares as a permanent investment. The consideration of these circumstances is the purpose of the present article.

The immediate danger which threatens the tea trade is that of over-production, with all its associated evils. Hitherto India and Ceylon planters have had a competitive market in which to place their increased output, but that market has now been won and fully supplied. The British market has shown tremendous elasticity in the past for the teas of India and Ceylon, but it has been very greatly at the expense of those of Chinese growth. China is now almost completely beaten out of competition, therefore the expansion of the home market for tea in the future must depend upon additional consumption per head, and the natural increase in the population. It is improbable that these possible sources of increased demand will be sufficient to take the increase in the crop which would result merely from improved cultivation of the old gardens, and it is altogether impossible that the British market can by any means take up the enormous increase in the output which must result from the very large extensions which are being made. The trade therefore depends upon the opening up of new markets—in Europe, America, Australia, and South Africa. Each of these continents offers the possibilities for a large trade, but in many instances they are pioneer, not competitive markets. Speaking broadly, they are not already occupied by another variety of tea, with which the product of the Indian and Ceylon gardens has only to be brought into competition to win, hands down.

In considering the value of the ordinary shares of British tea companies, it is of primary importance to gauge what probability there is of British-grown tea finding acceptance in these new countries. A large increase in the output in the immediate future may be taken for granted. If it needs to be substantiated, we have only to refer to the extensions of their old gardens which are being, or have recently been made, by nearly every company—in some cases very large extensions—and the new areas which are being brought into cultivation. We are informed by an old planter of many years' experience, that had there been sufficient labour to have gathered the whole of the Ceylon crop of last year, the market would have been glutted. This shows how imminent the danger of over-production is. There is no doubt that when, in the course of years, the young plants which have been put in during the last year or two, come into full bearing the increase must be something enormous. It is quite unnecessary to labour the point of how disastrous must be the effect of this large increase on the price of tea, unless the demand of the new markets is commensurate with the increase of the output.

What are the prospects of new markets? Take first America. The consumption of tea in the United States in 1890-92 was about eighty-two or eighty-three million lb.; in 1893 the imports were 88,000,000 lb.; in 1894,

91,800,000 lb.; in 1895, 96,500,000 lb.; and in 1896 over 100,000,000 lb. Canada imported in 1896 about 22,000,000 lb. These figures are unofficial, and too much reliance must not be placed upon them. The tea for American consumption, however, is supplied almost wholly from China and Japan. The consumption of British-grown tea, although increasing, is insignificant. According to Mr. Blechynden, the agent of the Indian Tea Association, Indian tea is displacing the China varieties in the American market. Although the capture of this market would be a valuable prize for the Indian tea industry, we do not think that it is in this displacement that British planters can look for relief from the threatened evils of over-production. The American consumption averages only $1\frac{1}{2}$ lb. per head of the population, against 8 or 9 lb. for the United Kingdom, and we note also that Mr. Blechynden, in his 1896 report, specially qualifies his statement regarding the displacement of China teas, by adding, parenthetically, "not Japan." This indicates that the energetic and enterprising Jap will prove a more formidable competitor than his neighbour, the Chinaman. We think, therefore, that the best chance for Indian and Ceylon tea lies in creating a demand of its own, not in attempting to take the market—and that a comparatively small one—from rival varieties. That would come later, in the natural course of things. British-grown tea is steadily making its way in the favour of our American cousins and Canadian brethren, as the following statistics, being the imports from 1890 to 1893, will show:—

1890 ..	2,364,152 lb.	1893 ..	4,211,075 lb.
1891 ..	2,635,772 "	1894 ..	5,379,542 "
1892 ..	3,208,655 "	1895 ..	9,283,144 "
	1896 (U. S.)		9,474,019 lb.

This improvement continues, and Mr. Wm. McKenzie, the agent of the Ceylon Association, reports that the shipments of Ceylon and Indian teas for London to North America in January and February of this year amounted to 1,202,000 lb. against 262,000 lb. in the corresponding months of the previous year. There was also a much larger shipment direct from Colombo and Calcutta, although he adds that the apprehension that a duty might be put upon tea may partly account for the enorm increase. Notwithstanding this, it is estimated that during the present year the American market will take upwards of five or six million lb. more than in 1896. If this expectation be realised—and there is every indication that it will—the outlook for British-grown tea securing at least a fair proportion of the American market is very favourable. Still there is the Japanese competition to meet. Already the Japanese Government has voted a sum of about 245,000 dols. to be expended over a period of seven years in the United States for the purpose of pushing the sale of Japan teas.

Outside of the United Kingdom, Australia is the largest consumer of British-grown tea. The tea drinking of the Australians is a by-word among nations, and it is in this market that the grower of Indian and Ceylon has the best chance of expansion, for here again he comes into competition with the China tea, which he has already shown he can easily beat. The quantity of British-grown tea consumed in the Australias is steadily increasing, having risen from eight millions to sixteen million lb. in the years 1891-6. In the last season the direct export from India and Ceylon was 17½ million lb. out of a total import into Australia of 28,000,000 lb. This represents a considerable displacement of the China variety.

The other great possible market is Europe, and here again the outlook is distinctly promising. Tea is coming more and more into favour in the countries of the

Continent. In the short space of five years the consumption has increased in Russia and Germany from 1 to $\frac{1}{2}$ millions lb.; in Turkey and Persia from $\frac{1}{2}$ to $\frac{1}{2}$ millions. The French have not yet taken to it. In 1896 only 200,000 lb. was imported, although this is an increase of 100 per cent. in five years. In all these countries, however, there is promise of very considerable development.

In determining the value of tea shares, it is also necessary to consider several circumstances which are much in their favour. For the most part the Companies are not over-capitalised, and, in the second place, speaking generally, they are managed by practical business men of great experience either in tea planting, or in the tea market at home, or who are well versed in Indian and Ceylon administration. There are, perhaps, fewer "ornamental" directors in this industry than in any other of equal importance in the City. The trade is also a secure one—for tea is not a commodity which is at all likely to lose its hold on public favour.

With combined and energetic action on the part of British planters the new markets indicated above should furnish an appreciable outlet for the increased outputs. If growers do not find some such outlet the price of tea, which has already fallen 2½ per lb. within the last few years, must fall still further.

ERRATUM.—In the statistical table in our previous article, the dividend on the ordinary or "C" shares of the new Dimbula Co. appeared as 6 per cent.; it should have been 14 per cent. The net profit of £20,323, on a capital of £86,200, made the mistake obvious.—*Investors' Guardian*, Aug. 21.

DRUG REPORT.

(From the *Chemist and Druggist*.)

London, Sept. 9th.

CINCHONA.—The auctions to be held in Amsterdam on September 30th will consist of 3,925 bags and 366 cases Java bark, details of which will be published next week. The stock in first hands now consists of 2,661 packages, exclusive of above quantity. The stock in second hands have also decreased by 1,500 packages. The exports of cinchona bark from Java during the period from July 1st to June 30th have been as follows:

	1896-7 Amst. lb.	1895-6 Amst. lb.	1894-5 Amst. lb.	1893-4 Amst. lb.
Private Plantations	8,826,536	8,401,282	8,030,536	6,961,296
Government Plantations	615,255	707,103	674,471	467,040
	9,441,791	9,108,385	8,705,057	7,428,336

COCAINE.—It is reported that one continental manufacturer is offering Hydrochlorate at 8s 6d per oz., but we have not heard of any business at this figure. The makers of B. & S. brand do not seem to be offering, though the nominal quotation is from 9s to 9s 6d per oz. Seven packages: crude have arrived, per the "Atrato," from Callao.

COCOA-BUTTER.—At auction on Wednesday 300 cases (30 tons), Cadbury's brand, sold at 11½d to 11¼d, the average being about 11 13-16th d. against 10½d per lb. in August. One hundred and fifty cases of Dutch were bought in at 10½d per lb. At the Amsterdam auctions, held on September 7, 85,000 kilos (84 tons) Van Houten's brand were offered, and sold at prices ranging from 60c to 63c per kilo (equal to 1s to 1s 0½d); 30,000 kilos (29½ tons) Hauser sold at 59c (equal to 11¼d). For 15,000 kilos (15 tons) Hollandsche 55c (11d) was bid, and refused; 7,600 kilos (7½ tons) Mignon were bought in, 5½c (11¼d) being refused. Of 4,000 kilos (4 tons) Suchard's brand offered, 2,000 kilos sold at 5c the remainder being bought in. On the whole, the market was irregular.

OILS (Essenti D).—Citronella oil is steady, but unchanged, at 1s 2d to 1s 2½d per lb. on the spot for either drums or tins. Owing to the continued rise in cloves the English oil has been advanced 1d per lb., making list-price 2s 3d per lb. for opt., and 2s 1d per lb. for B quality, these prices being without engagement considering the strong position of the article. Lemongrass firm at 2 11-16th d. to 2½d per oz. c. i. f. terms.

DEAFNESS. An essay describing a really genuine Cure for Deafness. Ringing in Ears &c., no matter how severe or long standing, will be sent post free.—Artificial Ear-drums and similar appliances entirely superseded. Address THOMAS KEMPE, VICTORIA CHAMBERS, 19, SOUTHAMPTON BUILDINGS, HOLBORN, LONDON.

THE AGRICULTURAL MAGAZINE, COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for October :—

Vol. IX.]

OCTOBER, 1897.

[No. 4.

SEASON REPORTS.

ESTERN Province.—Paddy. Yala harvest has begun; the excessive rains have to some extent damaged the crop.

Central Province.—Paddy. Yala crop being harvested in Kandy and Matale district. Rainfall registered at Matale 10.77 in.

Northern Province.—Paddy. Ploughing and manuring going on in Jaffna for next year's Kalapokam. Rainfall at Jaffna 5.41 in. Threshing of Kalapokam going on in Mannar as well as manuring of fields and tobacco gardens.

Southern Province.—Paddy. Yala harvest over and yield fair; good crop under Walawe channels. Preparations for Maha cultivation begun.

Eastern Province.—Paddy. Pinmari cultivation over 8,000 acres in good condition and ear. Murrain in some parts of Batticaloa South.

North-Western Province.—Paddy. Prospects of Yala crop good. Murrain in the Three Korales. Rainfall at Puttalam 2.11 in.

Province of Uva.—Paddy. Maha harvest still going on. Health of cattle good.

Province of Sabaragamuwa.—Paddy. Yala harvest in progress; prospects good. No cattle murrain reported.

North-Central Province.—Paddy. Crop maturing and being reaped, prospects good on the whole. Rainfall at Anuradhapura 1.83 in.

TREATMENT OF SUCKERS ON CACAO IN CEYLON AND THE WEST INDIES.

We are accustomed in text-books whether treating of agriculture or any other industrial pursuit to find certain hard and fast rules laid down for the guidance of the student,—rules, no doubt, founded on correct principles; but it would be the height of absurdity for the young agriculturist to stick by his text-book rules and regulations, and, irrespective of any modifying

circumstances, refuse to depart one hair's breath from their teaching. This would be as bad as the case of the enthusiastic novice who sallied into the field armed with a tome which he ever consulted before issuing instructions to labourers, regardless of the character of soil, rainfall, and other modifying conditions.

Many of our readers may have seen the textbook on *Tropical Agriculture* by Dr. Nicholls, a work which the Jamaica Government considered to be the best of those which were written in competition for a premium offered by it. In the end the work was published by the Government of Jamaica, it received the *imprimatur* of so high an authority as Dr. Morris, and was highly commended by the West Indian press. Dr. Nicholls states that his hope—expressed in his Preface to the first edition—that the book will prove serviceable to peasant proprietors, owners of estates, and intending settlers in tropical countries, is likely to be realized, while the fact that his work is being used in the colleges and higher schools in the West Indies is further testimony to the value which is attached to it. Dr. Nicholls himself accounts for the success of his *Tropical Agriculture* by stating that it "is due probably to the fact that it is not a mere compilation but the record of experience that has been gained by study, observation and experimental cultivation." So that it would appear that all West Indian authorities (including the good doctor himself) have accepted the book referred to as a standard work on the subject of which it treats.

Now the West Indies, where Dr. Nicholls has gained all his agricultural training and experience, is the home of cacao, and therefore may we expect to have sound advice as to the methods involved in the cultivation of the plant. We are, however, at present only concerned with the treatment of Suckers, and will therefore quote from *Tropical Agriculture* on this point.

In his chapter on Pruning, Dr. Nicholls thus refers to the treatment of suckers, no doubt speaking generally: "In all cases, however, suckers or robber stems, as they are called, must be removed from trees or bushes grown for their crops, as suckers rob the plant of much of the sap or food necessary for the growth of the flowers or fruit."
